Thus I have named just half a century of Orchids out of my own small collection, to which I have either applied or mean to apply cool treatment. If your correspondent will accept my counsel and consult Backhouse's list, he will possess a far wider scope for selection; and will find that the genera *Cattleya*, *Dendrobium*, *Epidendrum*, *Lælia*, *Lycaste*, *Oncidium*, and, *facile princeps*, the glorious genus *Odontoglossum*, are profuse in fine species, which will thrive under a greenhouse regimen. May I not add, that you will be glad to learn the results of his experience?—P. H. GOSSE, Sandhurst, Torquay.

### PRESERVING PEAS FROM MICE.

I HAVE discovered a most effectual method of preventing mice eating sown Peas. It may, perhaps, be useful to some of the readers of your Journal. If the Peas are soaked for about twelve hours in a strong mixture of sulphur and water previous to sowing, not only will the mice be prevented from attacking the seed, but the Peas will be stimulated in their growth by the immersion.—C. S.

CURIOUS EFFECT OF GRAFTING.—We extract the following from *The Naturalist*. "Some time ago, in a public garden of this place, a branch of Elm was grafted on an Oak in the expectation of obtaining a tree half of which would be an Elm and half an Oak. Contrary to the expectations of the gardener, however, the following was the result:—The tree commenced budding this spring, and when the leaves appeared it was found that each branch—nay even each twig, had both Oak leaves and Elm leaves growing upon it, in place of there being separate branches, each bearing a different kind of leaf. I will only add that the tree is in full leaf, and I have just obtained a cutting, which I intend to cultivate if possible; and I hope next spring to be able to inform the readers of the *Naturalist* of the result of my endeavours. I also enclose a sprig for your examination, and would like to ask, Is this a unique phenomenon, or has anything of the kind been observed before?"

It is certainly remarkable, yet not less strange than true.—  
T. G. H., Clifton, Bristol, Sept. 1864.

["The twig mentioned above has four secondary branches springing from it, and bears eight Elm leaves on the lower branchlets, and ten Oak leaves on the upper two. Can any of our readers state whether a similar occurrence has previously come under their notice?—Eds. Nat."]

**MR. ABBEY'S STRAWBERRY-HOUSES.**

MR. ABBEY'S first figure (page 154) is, I suppose, intended as a Strawberry-house *in toto*. Well, I have no objection to the large accommodation here for the production of such a luxury as forced Strawberries, but how are we to get at them to water the plants or gather the fruit? He has unfortunately placed the best of his structures in the wrong place. I mean the small one occupying the middle of the house. Were it not for this one could with a good deal of trouble get at plants on the "suspended shelves;" but as it is, it is impossible to work any of them, but the two lower ones.

Though there is no objection to having plenty of accommodation for forcing Strawberries, I believe such a house as this is quite unnecessary, and, moreover, it would be comparatively idle for six months in the year. Had the centre been occupied by a slightly raised bed, it would have made a better orchard-house than the one figured as such.

Before leaving this house permit me to state, that some years ago I saw the plan of a Strawberry-house, the principal feature of which was a structure running along the middle of the house quite similar to the small one in this, with this difference, however, that the glass was only about 3 feet from it; the shelves did not come so low, and a sunk path all round it afforded ample head room. The vacancy under it was to be filled with fermenting material, in the first instance to stimulate a root-action in the Strawberry plants, and afterwards Sea-kale and Rhubarb, placed on it for forcing. Such a structure, if only 30 feet long, and having but six shelves on each side, would hold about four hundred plants, which I imagine would be enough for a single batch.

Permit me now to allude to the other structures. "Strawberry shelves in a vinery." Here Mr. Abbey has ignored altogether the time-honoured and well-tryed back shelf, for a second edition of his suspended shelves, and not only so, but in his zeal for his pots, has actually forgotten the legitimate occupants of the house, for where are the Vines? Suppose for a moment they are bent along the front of the house, then when broken how are they to be got to their places? or where is there a place for them?

What gardener would recommend such a structure to his employer? or what gentleman would suffer such a weight of clay, iron, boards, and crockery to hang from the rafters of his vinery? Even if they occupied but the spaces between the Vines, where is the favoured locality in these islands that has so much sunlight to spare as these loaded shelves would obstruct?

"Strawberry shelves in orchard-house." This, as represented, will not commend itself to any one as an orchard-house; it is absolutely dangerous as a Strawberry-house. He has certainly put up a sufficiently high house, but then he has not given them (the orchard-house trees) the benefit of it, for in the only space left in this plan for them (the side borders) there is but 4 feet head room. He has appropriated their proper place, the middle of the house, to the means to get at the suspended shelves; but here I suspect the provision was unnecessary, for there is a great likelihood of the shelves and their burden coming down to him, if, as represented, they are all dependent from the upper shelf.

"Strawberry shelves in a Peach-house," are even more objectionable than in a vinery, for where are the Peach trees? Not trained to the roof, there is no place for them; not on the back wall, they would be useless there, with such an obstruction in front of them.—J. K.

[The figures at pages 154 and 155 were intended to represent shelves fixed near the glass in various structures for the forcing of Strawberries. They were not designed for vineries, for at p. 154 are these words: "Nothing is so good

as shelves about 15 inches from the glass—one along the front and another at the back of a vinery." Nor were they intended for orchard or Peach-houses; but, considering the great demand for room in most places, they were calculated to ease these structures by providing a house for forcing Strawberries. The structures best calculated to accommodate the greatest number of shelves were selected, being simply those which I had found from experience desirable for the purpose, and the only ones, in my opinion, that can economically accommodate a large quantity of Strawberries in a small space.

The structures best suited for the forcing of Strawberries are those with steep roofs; they receive more direct rays of the sun at the season of the year when the plants require such, they will accommodate more shelves than a flat roof, carry a greater weight, and the plants can be more easily attended to. It is a mere supposition of "J. K." that they were intended for any and every house, and his not being able to find the Vines, the orchard trees, and Peach trees, is because I was only writing about Strawberries. I was not writing of Vines, nor of orchard-house trees, nor of Peach trees, but of Strawberries, and placed them in the best position the structure appropriated to their growth afforded, being that where they can enjoy the sunbeams, and make the most of what is provided for their growth.

I set out with the intention of giving the Strawberries that which "J. K." finds I have done—a good position, and I state once for all they were all intended for Strawberry-houses. Provision had previously been made for their accommodation on shelves in vineries, one along the front and another at the back, then provision was made for their culture in houses separately devoted to their growth, it being presumed that the shelves in vineries, &c., were not sufficient to accommodate all the plants, and provision was also made for their accommodation in orchard-houses. True it is I did not state they were for "Strawberry-houses *in toto*." Some member of Parliament was said to be continually complaining of the press making him speak "what he did not mean, and leaving out what he meant to say;" but I have not a complaint of this kind to urge, for our friends at 17, Fleet Street have printed what I did not write as to the second, third, and fourth figures at page 155, I only being responsible for what is said of the first figure, and that is nothing, and I said nothing more of the remainder, for they were intended solely for Strawberry-houses, being such as I found best suited for providing the plants with a good position.\* What the figures were intended to represent I will state as briefly as I can.

Fig. 1.—Strawberry-house. The shelves are 15 inches from the glass, fixed by holdfasts to the roof, one to each rafter; the rafters are those usually provided for houses with lights, and are supported with inch-iron tie-rods from rafter to rafter across the house, and two the whole length, one of them being halfway up the rafters. Rafters 7 inches by 3 inches, will carry both the lights and the shelves, whether the latter be fixed at 36, 42, or 48 inches apart. The tie rods should be fastened with bolts that go through the rafters. All the houses are built in the same substantial manner, and will carry the shelves and their burden very well.

"J. K." objects to this figure on the ground that "the plants cannot be watered, nor the fruit gathered." There is a stage in the centre of the house, of which he thinks highly, but I only esteem it as affording easy access to the plants in the good position, and use it to stand upon. Two of the shelves he can reach from the floor, according to his own statement, and the others may be easily watered and the fruit gathered by making use of the stage, for from it the plants are more manageable than on stages where you have to reach beyond the equilibrium. All parts of the house are easily reached from the stage.

His other objection is "that the house would be idle fully six months of the year." Well, the house would be occupied with Strawberries from December to June; Vine plants on both sides of the house, one to each rafter, would be introduced in May, and tied down along the sides of the house. When the Vines were regularly broken, and the second batch of Strawberries fruited, the former would be trained to the rafters, the shelves being removed, one of their main

\* This is strictly true. Mr. Abbey put no descriptions to his drawings.—Eds.

features being that they are moveable. Now is the time to make a proper use of the centre stage by placing plants upon it, relieving the other houses, and enabling the cultivator to have finer plants in all. The advantages of *fig. 1* are, it is an excellent Strawberry-house for six months, and an excellent late vinery during the remaining six, its produce being two crops of Strawberries at a time when Grapes are raisins, stone fruits rare, Pears scarce, and Pines deficient in flavour, the only fruit then at its best being the Apple. Two crops of Strawberries would be worth something even in Covent Garden during the height of the London season, and the Grapes surely pay for the extra outlay in providing the shelves for the Strawberries.

"J. K." introduces us to a house of his own, one that he has seen (I tried mine), the chief features of which are that the plants are provided with a stage "only 3 feet from the glass," and the vacancy under the stage is filled with fermenting material "in the first instance to stimulate a root-action in the Strawberry plants, and afterwards Sea-kale and Rhubarb placed on it for forcing." It was some years ago when "J. K." saw this Strawberry-house, reminding me that it is now some years since I assisted at the turning of fermenting materials in a vinery, not thinking at the time that it was done expressly to stimulate root-action in the Vines which were in an outside border, which it was as likely to do as stimulate root-action in Strawberry-plants on a stage with a bed of fermenting materials under it, and also to destroy every leaf of the Strawberries, the young trusses, and the crop, if the steam were at all rank. Well, the house was 30 feet long, and held 400 plants, enough, says "J. K.," for a single batch; but what of the fruit? "J. K." forgets to tell how the house answered. This house is, I presume, given as a comparison. Granted the house *fig. 1* is 30 feet long, it would hold 1500 plants, in 4½-inch pots for fruiting early in March, and 1000 in six-inch pots to fruit in April and May, or 2500 plants in all. They are not 3 feet from the glass, but in that good position for Vines, Peaches, all fruits, and all plants, especially those of low growth, 15 inches from the glass, and I have proved that the fruit is then more plentiful, finer, and better-flavoured than when grown on plants at a greater distance from the glass. In "J. K.'s" house he places the plants in the worst position, and occupies the best himself, increasing the difficulty of attending to the plants.

*Fig. 2.*—This shows one of those houses known as an early vinery, which might be furnished with shelves for the forcing of Strawberries, and thus obviate the necessity of erecting a house on purpose, the house answering all the purposes of a late vinery. The shelves in this house are as easily reached as those in *fig. 1*, by using the stage to stand upon. We have exactly accommodation for the same number of plants as in "J. K.'s" house—viz., 400, or forty on a thirty-foot shelf, and two crops may be had from this house by May, and a crop of late Grapes as well.

*Fig. 3.*—This will commend itself to many as a span-roofed Peach-house, it not being intended for an orchard-house, but a Strawberry-house; I being the last to admit that a house having four rows of hot-water pipes is an orchard-house. *Fig. 1*, I quite agree with "J. K.," would make a better orchard-house, and, being 24 feet wide, and 15 feet high in the centre, allowing for a raised border, and a corresponding length, would be something deserving the name of orchard-house; but it is very questionable whether it would produce more, finer, and better-flavoured Peaches than *fig. 3*, which is only 12 feet wide, furnished with a trellis at 15 inches (not 3 feet) from the glass, and the trees trained so as to produce the fruit on young wood of the previous year, instead of on spurs, as in the case of orchard-house Peach trees closely pinched-in. Perhaps "J. K." will tell us whether he finds trees trained so as to produce their fruit year after year on spurs, or those bearing on the young wood of the previous year, considerably shortened at the winter pruning, give the most, the finest, and best-flavoured fruit? also, which trees are the least liable to the attacks of insects, and which remain in a bearing state the longest, and are in every way the healthiest and longest-lived trees?

I may observe, with regard to *fig. 3*, that it admits of shelves on both sides, and accommodates sixteen shelves and eighteen rows of Strawberries. The irons to support the shelves go through to the rafter upwards, and to them

outwards, being fastened in both places with screws. The reason they are not so represented in the figure is, the upright part of the iron passes through the shelves, and cannot be seen from the floor, and so are those in *fig. 4*. The roofs of these structures being steeper, carry the shelves very well, the rafters being properly supported with tie rods. Five of the shelves, and six rows of plants, can be watered from the floor, and the remaining three by placing a plank across the tie-rods at 6 feet from the floor, a boy handing up the water; or a step-ladder can be employed, and half a dozen plants watered at the same time. This house would give two crops of Strawberries by May, when the shelves could be taken down, or they might remain, and numbers of Primulas, Cinerarias, Calceolarias, and other plants be forwarded thereon. The shelves being taken down, and Vines in pots at hand, these would be trained one to each rafter, they having been previously accommodated in a cool house. Between them space will be found for young plants raised in January from eyes, and these, if then transferred into their fruiting pots (the turves from the shelves being the material for them, the Strawberries for another season's forcing also liking the same), will form strong canes to fruit in the place of those now fruiting. Thus we have a crop of Grapes in October up to Christmas, and two crops of Strawberries, besides Vines for fruiting another year.

*Fig. 4.*—This is, ordinarily, a lean-to Peach-house, now converted into a Strawberry-house, wherein "J. K." will see one of his "time-honoured and tried back shelves," and eight more on the roof. It is simply one-half of *fig. 3*, and, like it, could be employed for Vines after forcing Strawberries, as a Fig or Melon-house, or be used for plants, as thought proper.—G. ABBEY.]

[We have, as we invariably do, omitted, as much as possible, all sarcasms and all ridicule from this attack and defence. It is extraordinary that men cannot search for truth without endeavouring to wound those who are devoted to the same research.—Eds.]

#### THE EARLY TEN-WEEK POTATO.

SOME twenty—aye, or more—years ago, I received from a Mr. Chatwin, a Potato merchant at Hungerford Market, near Charing Cross, a list of different varieties of Potatoes. I was quite astonished to find such a long list of names, as I then thought there were but very few sorts of Potatoes known. I remember being struck with the name "Early Ten-week," for I thought it must be something new and good. I therefore ordered a peck, for which I paid some 10s. or 12s. They were carefully planted and attended to, but to my great disappointment a great portion of them proved twenty-week rather than ten-week; in other words, they were dreadfully mixed with some late sort. Some few, however, were really the true thing, as they were dwarf and very early, reminding me of a very old sort that had been here for generations, and called the Early Betsy. I mention this because we have, I think, had for many, many years some dwarf early kind of Potato under different names—almost a species in character. Well, my selected Ten-weeks proved better, or we thought so, than Betsy, and she, poor old girl, was dropped. Many old friends have in like manner been dropped, only because new ones have sprung up. A truce, however, with moralising. I hate essay-reading and trite moralisms. What a number of moral sermons have I heard from our old pulpit! They were, I suppose, fashionable when I was a youth; I know they were very common. What a delight it was to hear "Lastly, my brethren!" and how we bolted from the dear old church on a fine summer's day!

Well, "too far have I got," as a young German from Vienna, who was coming to stay with me, wrote on a large card and held it before the old coachman's eyes when he saw my house, which he guessed was mine from the description of it given to him. Alas, poor old Gibby! how full of fat and fun he was! "Too far have I got." What does he mean, John?" (to his guard). "I'm blown if I know," says John. Again the card was pushed before Gibby's nose. "Too far have I got?" this time with a note of interrogation; but coachee did not know the "little crooked thing." A shake of the head and a whip of the horses, and the coach

bowled along to Bishop Stortford, where a German lady was found, who told the unlucky German that he had got too far by four miles; and so the next morning he was brought back and safely deposited at my house. That great card which I saw held before coachee's eyes, who stopped a minute on the brink of the hill "dubitating," will never leave my memory, nor the hearty laughs we had with Brifhaut about it when he had learnt English.

Well, I have got too far, and have left Early Betsy and ditto Ten-week somewhere. I must "resume the thread of my interesting narrative," as the novelists say, by stating that after selecting the true kind from the medley received, I cultivated the sort to some extent, and distributed it in the neighbourhood—among others to Mr. Moffat, who exhibited this kind at South Kensington last autumn, and obtained a prize for it. I mention Mr. Moffat's name in conjunction with the Early Ten-week Potato, because he corrected an error into which I had fallen. When the Early Handsworth was sent out a few years ago I hastily concluded that it must be the same as the Early Ten-week; but Mr. Moffat says that it is a much better sort both in flavour and earliness. I have thought it worth while to give the history of this old and interesting Potato; and as the true sort is scarce, to observe that its usual form is a blunt oval, but many round tubers are usually found. It is very early, its habit dwarf, and it does not bloom. Probably it is one of our best early round Potatoes, and is quite worthy of culture for forcing and for a first crop.—T. R.

### HADSOR HOUSE,

THE SEAT OF — GALTON, ESQ.

THIS residence is one mile from Droitwich. At the entrance gates is a handsome lodge, the drive from which winds along the side of a hill between plantations and groups of Furze, with a Gothic cottage nestled among trees below to the right; on the left is ground, diversified in surface, rising above the drive, and planted with groups of forest trees, interspersed with handsome specimens of Hawthorn. The drive then passes through a large plantation of Oaks, extending on the right through a deep dell, and on to the house. On the west side of the house the terrace was furnished with large specimens of variegated Aloes in vases, and on a lower level are flower-beds on grass. On the north side below the terrace is the Rose garden furnished with all the best sorts of Roses. Attached to the house is a conservatory 65 feet long by 36 feet wide gay with Passion-Flowers, Tecoma jasminoides, Mandevilla suaveolens, Brugmansia sanguinea, and B. suaveolens, planted in the border. The Brugmansia suaveolens was the finest specimen I have ever seen. It was 15 or 16 feet high with about three hundred large, white, trumpet-shaped flowers hanging down from all parts of the tree. The succulence and rapidity of growth apparent on its branches, and the prodigious numbers in which it develops its gigantic, snowy white, and sweet-scented blossoms, mark it as one of the most magnificent of conservatory plants. This fine exotic is too much neglected in collections on account of its liability to the attacks of the red spider. Having hitherto seen but poor sickly specimens with straggling flowers of tawny hue, my delight at beholding this Peruvian beauty in all its splendour may be conceived. Many of the blossoms were 12 inches in length, and 7 or 8 inches across the mouth of the flower. There were also Passiflora edulis bearing fruit used at the dessert, fine specimens of Camellias, and Orange trees. In a niche in the centre of the conservatory were a marble statue of Venus, and a fountain. There was great taste displayed by Mr. Dalrymple, the head gardener, in the arrangement of the plants in the border, and grouped beside the pathways. A terrace walk leading from the flower garden to the temple is ornamented with vases; and on the right a peep may be obtained of the pleasure grounds and a lake at the bottom of the lawn, with all sorts of water fowl.

The pleasure grounds contain some fine specimens of Spruce Firs well feathered to the ground; Pinus excelsa; Sumachs in their autumn scarlet livery; Pinus pinsapo, infested by wasps to such a degree that Mr. Dalrymple feared the trees would be ultimately killed by them, although he was adopting every means to insure their destruction; also,

Turkey Oaks, Wellingtonias, Cryptomeria japonica, 25 feet high, and 16 yards in circumference; Taxodium sempervirens, 25 feet high; and a Deodar Cedar, 27 feet high. There are Cypressess, Red Cedars, Ilexes, and Turkey Oaks, with other trees and shrubs of diversified foliage in another portion of the pleasure grounds to represent Italian scenery.

After admiring for some time the rich and gorgeous scenery produced by the autumn tints of the foliage we descended to the fernery, composed of old roots and stumps of trees with arches to walk under, to admire the various British species of Ferns that are planted in the crevices, and kept moist by an underground pipe from the fountain in the conservatory, the water from which can be made to trickle over them when required. The plumed Ferns, but lately so light and green, were then clumps of blackened fronds hanging over the old roots, whose nakedness they covered so tenderly during summer. On the edge of the lake is a hollow old Oak with a seat in the middle, where a person may sit and contemplate the manifold beauties of Nature around him. The following lines of Cowper, who had a keen sense of the beautiful, are applicable to this picturesque object.

"Thou wert a bauble once, a cup and ball,  
Which babes might play with, and the thievish jay,  
Seeking her food, with ease might have purloined  
The unborn nut that held thee, swallowing down  
Thy yet close-folded latitude of boughs,  
And all thy embryo vastness at a gulp.

\* \* \* \* \*  
Time made thee what thou wert—king of the woods,  
And Time hath made thee what thou art."

Further on is a grass walk with a Yew hedge at each side leading through a grove from the ornamental water to the keeper's lodge. Returning by the terrace walk from the bulling to the bear, so called on account of a representative of the grizzly animal at the end of the terrace walk, we pass through a plantation of trees and shrubs to the kitchen garden. The horticultural structures are a span-roof Orange-house 36 feet by 27 feet, containing good specimens of Orange trees, Lemons, and Citrons; a greenhouse 36 feet by 14 filled with Azaleas, &c.; three vineries, ridge-and-furrow, the middle one 48 feet by 17, with a high roof, and the other two, one at each side of the middle one, 42 feet by 15 each. They contained good crops of Muscats of Alexandria, Black Hamburg, and Barbarossa, bunches of the latter averaging about 4 lbs. each. There are besides a Peach-house 80 feet long by 6 wide, with healthy Peach and Nectarine trees that had, in the summer, borne fruit of the average weight of 8 ozs. each; a range of Pine-pits 72 feet long by 16 wide, for fruiting and succession Pine plants, and containing some good examples of Queens, Black Jamaicas, and Smooth Cayennes; and a range of pits, also 72 feet long by 16 wide, for forcing French Beans, Strawberries, Potatoes, and many other things, all heated by hot water.

These grounds are naturally varied and tastefully arranged. The woods, pleasure grounds, roads, walks, drives, and plantations with the kitchen garden, horticultural buildings, and the various scenes connected with them, have been laid out in the best manner to give a pleasing succession, and a harmonious effect to the whole.—WILLIAM KEANE.

### SOIL FOR RHODODENDRONS.

HAVING just read Mr. Robson's article on Rhododendrons, and having had some experience in growing them in uncongenial soils, I think I may be able to give some useful hints or information to those similarly circumstanced.

When living in Ireland on a limestone formation surrounded by large black peat bogs, which furnished excellent fuel not only to the poor but to the gentry around, I tried this turf mould, or "bog stuff" as it was called, for Rhododendrons, but they barely existed in it, and never flourished, though it formed an excellent manure for most vegetables and flowers. Several of my neighbours attempted to grow them, but with no better success. One person, however, had a large bed of them growing most luxuriantly, and his mode of proceeding was this: He dug a large hole or pit several feet in diameter and about 2 or 3 feet deep, and this he filled, not with the rich-looking black stuff which others as well as myself had used, but with the surface sod

if I may so call it, of this black stuff. He skimmed the surface of the bog, taking Heath, roots, and all that grew there, and filled his pit with them, chopping them up, and his Rhododendrons flourish and flower there most perfectly, while they fail all round him. I did not hear of this plan until I had left the neighbourhood, so did not try it myself as I should otherwise have done.

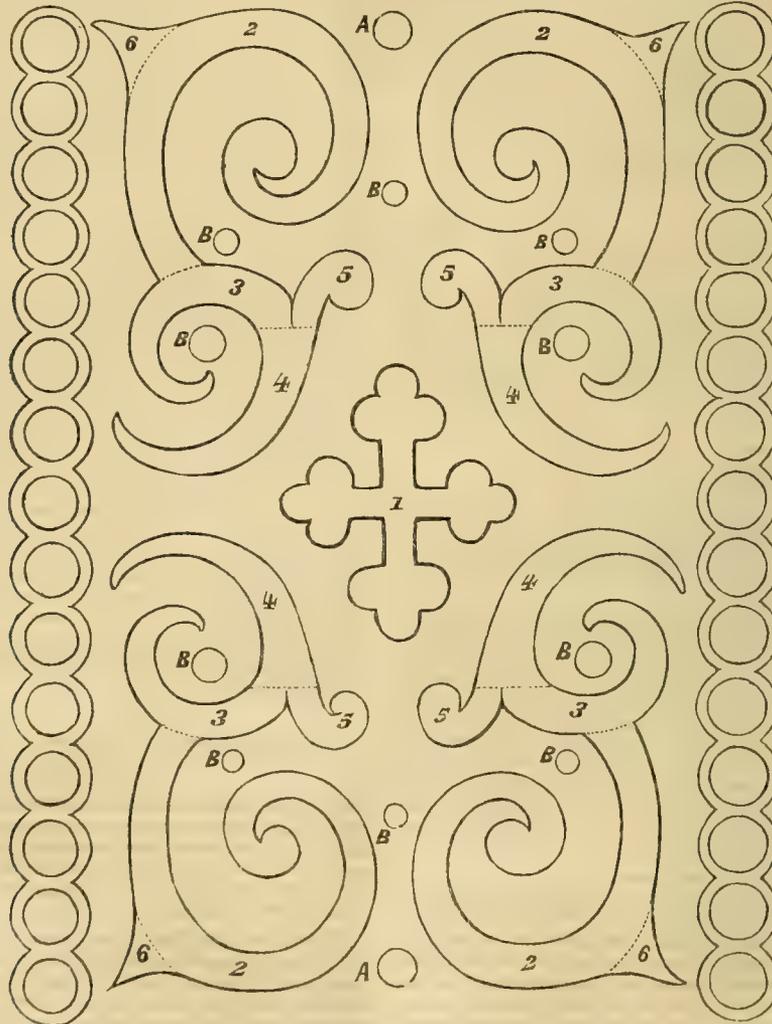

I am now living within a few miles of Dublin (south side), on a granite formation, and I find that the numerous nursery-men around get all their Rhododendron mould from some mountains eight or ten miles off, paying 6s., or at the least 5s., for a small cartload of this. I have myself had to pay at times 8s. a-load. This stuff is, like my friend's, composed

of the top, or surface sod, from 3 to 6 inches deep, with Heath, roots, &c., growing on it; and in this quite pure the hybrids, as well as the common kinds, grow perfectly. All the neighbouring gentry grow them in the same manner and with equal success. The nurserymen tell me that the best substitute for this is leaf mould pulverised; but the growth of the plants in it is so far inferior that they find it well worth their while to pay for this stuff drawn from a distance. In some parts of Ireland Rhododendrons grow so freely without culture that I have had sods of self-sown seedlings sent to me from thence.

I agree with Mr. Robson that where the Foxglove grows they will grow.—A. B.

### FLOWER-GARDEN PLAN.

NORTH TERRACE.

TERRACE.

The above design is from Mr. Thomas Sampson, Houndstone House, Yeovil, and is proposed to be planted this year as follows:—

- 1, Centre, *Centaurea candidissima*.
- Second row, *Amaranthus metachoffens ruber*.
- Third, or outside row, *Mrs. Pollock Geranium*.
- 2, Variegated *Geranium Alma*.

The circles in the centre of the chain, along each side, *Stella Geranium*. Rings surrounding the circles, and forming the chain-pattern, *Cineraria maritima*.

A A, *Golden Chain Geranium*; B B, *Centaurea gymnocarpa*.

- 3, *Christine Geranium*, pink.
- 4, *Calceolaria Aurea floribunda*, yellow.
- 5, *Purple King Verbena*.
- 6, The four corners yellow.

The only alterations we have suggested are to continue the chain along both ends, if the position will admit of it, leaving an opening in the centre of each end; to plant the small circles with upright evergreen shrubs; and, instead

of dividing the four scrolls into separate colours, to plant the centre bed and chain-borders with scarlet and white, so that the scrolls might be crossed with pairs of purple and pairs of yellow.

### LA CONSTANTE STRAWBERRY.

THE drawbacks to La Constante Strawberry, as stated by Mr. Radclyffe, resolve themselves into these:—

1. It is not sufficiently hardy.
2. It does not produce runners enough.
3. The runners not being produced till after fruiting, cannot be used for autumn planting.
4. In summer the leaves are scorched by the sun.
5. The fruit is ripened simultaneously, and
6. When ripe it must be gathered at once, and eaten immediately.

If any of these objections were founded on facts observed in different situations, La Constante would not be worth retaining in cultivation. As to the hardiness of the plant there is only one opinion, and that is in conformity with Dr. Roden's; besides, the plants have stood the test of the severe winter of 1860-61.

As regards the second point, it was settled fifteen years ago, and the principle then laid down is recognised as correct—that to send out runners moderately, and to do so after the crop has been gathered, constitute two of the greatest merits which a Strawberry can possess. If the runners are not fit for planting in the autumn of the year in which they are produced, they are left round the plants to gain strength, and are in the best possible condition for planting in the following March or April. If carefully planted in spring, as many good fruit can be depended on from them in the following July as from any other variety planted in autumn. If the above assertion appears doubtful to any of your readers, I will give them twenty-five runners of La Constante if they will defray the expense of carriage, which would not amount to more than from 1s. to 3s. according to distance.

During the ten years in which I have grown La Constante I have never observed, either here or elsewhere, that the leaves are liable to be scorched by the sun, and such a peculiarity has never been remarked by any of my correspondents. But if the leaves have been anywhere found to burn, I believe the cause to have been ill-timed watering, or planting and transplanting without having first removed the ball of earth from the roots—a matter of such elementary importance as only to require mention.

Does the fruit of La Constante ripen all at once? The contrary is the fact; for it is well known to Strawberry growers that the bearing of this variety lasts from a fortnight to five-and-twenty days, and that the last-gathered fruit are as fine as the first, if in dry weather the plants are well supplied with water.

The sixth objection rests on no better foundation than the five preceding it. There does not exist, so far as I am aware, a Strawberry of which the fruit will keep so long as that of La Constante. It is precisely on account of its continuous bearing and long keeping, that experienced growers near Brussels have planted it largely for supplying the market.

If any of your readers who has grown La Constante for two years does not agree with what I have stated in this article, by making his conclusions known, he will, I think, render a service to Strawberry-growers in general, and contribute to the solution of the questions which have been raised.—J. DE JONGHE, *Brussels*.

### CLIMBING DEVONIENSIS AND ROSE SPORTS.

It would seem that a few more remarks are needed to satisfy the minds of some of your readers that the climbing Devoniensis Rose is really something distinct from the old well-known variety. Owing to a supposition, arising out of a letter from Bath in your columns, that it is the same grown under certain conditions, I have had a package of fifty-two plants returned to me.

I must adhere to what I have already stated that I have proved it to be a most distinct sport, now thoroughly fixed, from our old friend and favourite, and of so distinctive a character as to be honestly called the Climbing Devoniensis, if a Devoniensis may be so called which equals Cloth of Gold in vigour of growth and habit of climbing, with the hardiness of Gloire de Dijon or a Hybrid Perpetual.

It is interesting to trace the origin of the sport, and I was not aware that it could be done until I read Mr. Pavitt's letter in your paper. I am, therefore, most happy that he

should have the credit, according to his statement, of having obtained the sport from the Celine stock. The history of the Rose as far as I am concerned is simply this: During a journey on Rose business in some of the neighbouring counties I found that several gardeners possessed what they called a strong-growing Devoniensis. I did not visit Bath in my rambles, nor have I the pleasure of knowing Mr. Pavitt personally, but hearing that he had some stock of this strong-grower, and being particularly interested in the Devoniensis Rose, I sent to purchase some buds from him, wishing to prove it for myself, not however with the idea of anything distinct. Many of the buds failed, but out of the living ones about two-thirds came not distinguishable from the old variety, the rest assumed a very distinct and remarkable habit. These were again very carefully budded on suitable stocks, and I soon perceived their decidedly running character which has been again improved by budding.

And now a word on its hardiness. Out of a piece of more than 3000 buds and shot plants, though they have been many times covered with ice during this late most inclement and trying season, and buds of Narcisse and others have been killed near them, I cannot perceive the slightest injury inflicted on one of them by frost.

Although I have myself budded many thousand Devoniensis on the Celine without such a result, I cannot but feel gratified that this magnificent climber has been obtained from that stock, which I was the first to prove an excellent one for budding upon more than twenty-five years since, and to introduce publicly for that purpose, challenging Mr. Rivers to try it against his Manetti stock. Though the Manetti has proved so invaluable, yet the Celine is equally so for Noisettes and some varieties.

A few years back I obtained a sport from Elise Sauvage, Tea, by budding it on the Celine, the shoots came from 3 to 4 feet in length and were fixed. The foliage and buds were exact counterparts of the parent, but without the beautiful orange-coloured centre so charming in Elise Sauvage, so that we subsequently decided not to work it.

While on the subject of sports it may be interesting to mention that in the year 1840, observing a running or barren shoot on a plant of the old Aimée Vibert Noisette, I immediately budded it on the Celine and fixed it, and I had the pleasure of first sending it to Mr. Rivers as a climbing Aimée Vibert, which character it has since maintained.

In closing I would earnestly impress on my brother Rose-growers and budding friends to see that they work the Hybrid Perpetuals only from flowering shoots, as there is a tendency, now that class of Roses is so luxuriantly grown on root stocks, to throw them into shy autumnal bloomers by budding from excessively long or barren shoots.—HENRY CURTIS, *Torquay*.

### NUMBER OF WORKING HOURS FOR GARDENERS.

WILL you inform me the number of hours' work per day that a master has a right to expect of his gardener? I hold that ten hours' work per day during the summer months, say from 6 o'clock A.M. to 6 P.M., with two hours for meals, is not too much when we consider the short days during winter.—W., *Yorkshire*.

[We agree with you that from 6 A.M. to 6 P.M., with two hours for meals, are very good hours during the summer months. If the gardener lives at a distance from his work, forty minutes may be required for breakfast instead of thirty minutes, and the same for tea—say breakfast at 8, dinner one hour, at 12, and tea at 4. In many cases where the gardener has to go a distance, he foregoes the tea, or takes something to eat with him, and perhaps a glass of beer instead. Though we say this much, we would advise every gentleman who has a gardener worth keeping, not to be too particular at all times as to these hours. A gardener who sees that things require to be done will not be watching for the clock to strike 6; he will rather feel annoyed that the time has gone too quickly, and to keep things right will often work much later, and come earlier in the morning too. There are many things which are better done in the cool of the evening and the haze of the early morning; but if a

gentleman shows annoyance if a gardener is either behind 6 in the morning or locks up at times before 6 in the evening, the gardener, with all due respect to his employer, and without being anything of an eye-servant, may in return rigidly keep the prescribed hours, and yet not be able to give himself or his employer the same amount of satisfaction. Still, if only one or two men are employed, it is best in general to keep to these regular hours. Where a number of men are employed, whatever the time agreed upon, that time should be rigidly kept without any irregular deviation. Few things are more annoying, than to stand on a morning for ten minutes or half an hour waiting for men to come; or to see men only appearing to work, that the job may be drawn out until the hour strikes at night. The give-and-take principle will generally be found to work the best; but when the gardener takes back a little time he will act wisely to do so with the full knowledge and consent of his employer. There will be no disappointment to the latter then, if he does not see him at either of the hours referred to.

It is now happily becoming common for mechanics and workmen to leave off work at an early hour on Saturday. In most cases this would be unsuitable in gardens, but that is no reason why the gardener should not have a holiday at other times, and especially when he works often cheerfully before and beyond his hours. We hold then with "W.," that from 6 to 6 are very general and reasonable hours; but if that is rigorously insisted on, it cannot be expected that a gardener will long continue to do necessary jobs beyond these hours, unless, indeed, he is paid for that overtime. In all gardens of large extent where there is much of this work in extra hours, it is the most satisfactory plan to pay for it, and then strictness to hours may be insisted on without any want of kindness on the one hand, or respect on the other. Even then we know from experience, that a holiday freely given is anything but a loss to the employer. It often makes all the difference between working as a matter of duty, and working as a pleasure, from the heart-felt desire to give satisfaction to those we respect—a very different thing from merely filling up the time until the clock strikes. Knowing and feeling all this, we are great advocates for regularity in time, so much so, that we would have all deviations regular and a matter of thorough understanding between the master and the servant.]

#### DR. HUGH FALCONER.

THIS eminent naturalist was born at Forres, in Morayshire, on the 29th of February, 1808, and was, consequently, at the time of his death in his 57th year. He was educated at King's College, Aberdeen, where he took the degree of A.M., after which he studied medicine at the University of Edinburgh for four years, and became M.D. in 1829. Having been nominated to an assistant surgeoncy in the Bengal Army, but not having attained the requisite age, he employed the interval in assisting Dr. Wallich with his Indian herbarium, and in the study of geology and palæontology.

In 1831, he was sent in charge of invalids for the sanatorium of Landour, in the Himalayas, and passing through Suharunpore, where the botanic gardens were then under the superintendence of Dr. Royle, a friendship was soon formed between the two, and on Dr. Royle's leaving India, Dr. Falconer was appointed his successor. "Thus," says the writer of a memoir of him in the *Athenæum*, "at the early age of twenty-three did he find himself advanced to a responsible and independent public post, offering to a naturalist the most enviable opportunities for research; so fertile was the Indian service then in chances to rise for any young officer who chose to make the exertion. Suharunpore is situated between the Jumna and Ganges rivers, outside the belt of the Tarai forest, which lies between the mountains and plains, and is distant about twenty-five miles from the Sewalik hills, beyond which rise the Himalayas. It is thus most favourably situated as a central station for natural history investigations,—the rivers, plains, forests, and hills teeming with life in every shape, and the range of elevation combining, within a short distance, the features and productions of tropical, temperate, and alpine regions insensibly blended. Being a remote provincial station, with only half a dozen European families, the white man had to draw on

local means in all emergencies where the appliances of civilised life were required; but the intelligence, docility, and exquisite manual dexterity of the natives, backed by their faith in the guiding head of the European, furnished an inexhaustible fund of resource. To construct, for example, a barometer for mountain explorations, broken tumblers were melted and blown into a tube, mercury was distilled from cinnabar purchased in the bazaar, a reservoir was turned out of boxwood felled on the mountains, and finally a brass scale was cast, shaped, and even graduated, by a native blacksmith, under the superintending eye of the amateur. Such discipline was of value in training the young officer to habits of self-reliance, and to kindly relations with those among whom his lot was cast, and no doubt contributed to that great fund of information for which Falconer was remarkable."

Here he pursued his geological and palæontological researches, investigating, in conjunction with his friend, Sir Proby Cautley, the fossils of the Sewalik Hills; and the result of their labours was their discovery, jointly with Lieuts. Baker and Durand, of a sub-tropical mammalian fossil fauna of unexampled richness and extent.

A commission having been appointed by the Indian Government in 1834, to inquire into the fitness of India for the cultivation of Tea, and Dr. Falconer having recommended the attempt, plants were imported and placed under his charge. Since then the cultivation of the Tea plant has extended over a large portion of northern India and Assam, and is still extending.

In 1843, he was appointed to succeed Dr. Wallich, as Superintendent of the Calcutta Botanic Garden (now left little better than a wreck from the effects of the terrible cyclone of last year), and whilst holding this position he recommended the introduction of Cinchonas into India, pointing out the hilly regions of Bengal and the Neilgherrie Hills, as the positions most likely to insure the successful cultivation of these invaluable medicinal plants. Years afterwards this suggestion was carried out, and there are now many thousands of plants both in India and Ceylon. In 1855, Dr. Falconer came home and continued his favourite researches among fossil remains up to the time of his death, which resulted from an attack of acute rheumatism, coupled with bronchitis, terminating in congestion of the lungs. His writings were chiefly scattered over the *Geological and Philosophical Transactions* and other scientific Journals; but, to quote the words of the writer in the *Athenæum*, "the work which he published was but a small fraction of that which he actually accomplished. The amount of scientific knowledge which has perished with him is prodigious, for he was cautious to a fault; he never liked to commit himself to an opinion until he was sure that he was right; and he has died, in the fullness of his power, before his race was run. Those who knew him well can best appreciate his fearlessness of opposition when truth was to be evolved, his originality of observation and depth of thought, his penetrating and discriminating judgment, his extraordinary memory, his scrupulous care in ascribing to every man his due, and his honest and powerful advocacy of that cause which his strong intellect led him to adopt; whilst they, more than others, will have occasion to deplore the death of a staid adviser, a most genial companion and a hearty friend."

#### FRENCH VERSUS ENGLISH ASPARAGUS.

I COULD not sooner reply to the observations of our friend "G. A.," in your No. 197, because, to be very candid, several of my friends, interested in the discussion, insinuated that I might be wrong in my estimation of French Asparagus, which they had considered to contain more white on the shoots than did the English. I therefore determined to write to my French friend in whose gardens I first saw the beds laid down by L'Hérault, and who is himself a very fair horticulturist. I think his letter will be interesting to your readers, and, therefore, give you a translation of it.

I cannot consider "G. A." quite fair to me, when he writes—"We do not measure the value of Asparagus in England solely by its appearance, but according to its utility." Such a remark appears as though he intended your readers to infer that I did, whereas, nothing I have

said warrants such a conclusion, and after perusal of my friend's letter, it will be seen that utility, by which I presume is meant the larger amount of edible matter produced enters as a large item in my argument.

"G. A." has, probably, never eaten French Asparagus under the favoured conditions described by my correspondent; but he may have done so at some restaurant in Paris, if he has been there, or from some of our markets eight and forty hours, probably, after being gathered, after being subjected to a long voyage, and badly packed, and badly cared for. He will forgive me, therefore, if I hope he will say no more about "stick liquorice," or the "roots of an old Elm tree"—two comparisons quite irrelevant to the subject. Upon one point I will not presume to dispute with him—viz., his assertion that, "As fine Asparagus has been grown in England as was ever grown in France, if that alluded to be the heaviest grown there;" I suppose him to be a horticulturist by profession, and will not enter into the lists with him. I can only say, that neither I nor any of my friends, who have been at a great many of our best shows, have ever seen anything approaching to them. He appears to look on me as one of those who think nothing good in their own country. I beg to assure him, that I am as out-and-out an Englishman as he can be, only I do not disdain to learn from any one of any country who can impart knowledge to me. So I hope he will shake hands with me.—H. S. WATSON, *Cottage, Charlton.*

Extract of a letter from M. Carlos Forer, of Margency.

February 26.

"L'Hérault is beginning to plant out Asparagus, and I have, therefore, ordered him to send you at once what you require. Those who object in THE JOURNAL OF HORTICULTURE to your estimate of French Asparagus, may say what they please, but I can bear testimony that L'Hérault grows it to perfection. There are some amateurs who maintain that that with green ends is preferable to the rose and white, as grown by him, but we are certainly not of that opinion.

"To eat Asparagus, however, in perfection, a few precautions must be observed:—

"1st. It should be gathered before the rising of the sun, and should be eaten during the same day.

"2nd. If required to be kept twenty-four hours, it should be put into fine and rather moist sand, leaving 2 or 3 inches only exposed.

"3rd. Care must be taken after gathering and cleaning it, neither to allow it to be wetted nor to be exposed to the sun.

"Our Asparagus, although planted by L'Hérault, is neither so long nor so thick as that grown under his immediate supervision, but it is very fine and very excellent, and in answer to your special question, as to the quantity edible, I should say that we eat nearly all of it. I am quite sure that not 2 inches goes from the table. I can very well understand, that the case is not the same with that eaten at the hotels and restaurants of Paris.

To sum up. If the English be equal to the French, how happens it, that in the season it is the English who are the great buyers of it in the Halles of Paris, at from 25f. to 30f. the bundle, and from whence they send it to the London markets to be eaten by your rich consumers, who do not and cannot get it as I describe it, owing to the length of time that must elapse before it can be brought to their tables; and it is for this very reason that L'Hérault is so anxious to find a London agent, as when the railway passes Argenteuil, which it will do shortly, he will be enabled to cut it and have it eaten in London within the twenty-four hours.

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

At the time of earthing-up any of the crops strew a little soil close to the stems of the plants; this will prevent slugs harbouring there and nipping them off under the surface of the soil, which they are very apt to do in the early part of the season. Loosen the earth between the winter-standing crops, and keep every part of the garden free from litter. *Asparagus*, the general spring dressing, if not yet done, should no longer be delayed, as the roots will now begin to move. *Beans*, make another sowing; the Longpod is a

prolific sort, but the Green Windsor has the best appearance when sent to table. Earth-up the early crops. *Capiscums*, pot-off the young plants as soon as fit and place them in a hotted frame; they are very subject to the green fly, which should be destroyed as soon as it is observed. *Carrots*, the weather is now favourable for getting in the main crop. The Early Horn is an excellent sort both for early and late crops, and is much better adapted for many soils than any of the others. *Celery*, prick-out the early-sown into boxes or on a slight hotbed; when it has taken root give air at every favourable opportunity. *Cucumbers*, as soon as the frames are uncovered in the morning give a little air for an hour, when they may be closed again till the day is further advanced; if air has been given to the frames all night they may be closed for an hour or two. As soon as the principal shoots have reached the sides of the frame, do not allow any of the laterals to grow more than two joints before being stopped. *Kidney Beans*, make another sowing in pots. Keep the bearing plants frequently syringed to check red spider. *Lettuce*, some of the best plants that have been wintered in frames may now be put out, some under a south wall and others in a more open situation. *Onions*, sow the main crops if not already done; if very large ones are required plant the very small bulbs of last year, or the autumn-sown plants, in very rich ground. Larger Onions may be grown by the following method: Well tread the ground, and lay 3 inches of very rotten dung upon it; on this sow the seed, and cover with a little fine earth. *Peas*, stick the early crops as soon as they are earthed up; a few small Hornbeam boughs with the leaves on may be stuck on each side of the row, this will protect them from cold winds. *Purslane*, make a sowing on a warm border. *Radishes*, sow for successional crops; the Turnip-rooted sort may now be sown. *Rhubarb* may be forwarded by placing a hand-glass over the roots. A little litter should be laid round the bottom of the glass to prevent the ingress of cold. *Savoy*, make a good sowing of the Dwarf Green, which is best for general purposes. *Salsafy* and *Scorzonera* should be sown in drills from 9 inches to a foot apart. Now the weather is favourable for the purpose clean and move the ground between the rows of Lettuce, young Cabbage, autumn-sown Onions, Garlic, Shallots, and other winter-standing crops; clear the garden of all rubbish, and let general neatness prevail; lay down and roll the walks if they have been loosened by the winter.

### FRUIT GARDEN.

When Peach, Nectarine, and Apricot trees are coming into flower, put up coping-boards and curtains, or nets, or, in the absence of these, a few spruce fir boughs may be stuck about the trees. Continue re-grafting bad sorts of Apple and Pear trees. Securely stake newly-planted standard fruit trees, nothing is more injurious to them than being blown and twisted about by the wind.

### FLOWER GARDEN.

Sweep and thoroughly clean lawns, and give them a double rolling with a heavy roller, to render the turf smooth and solid. If any alterations or planting still remain unfinished, every available hand should be concentrated on this work so as to complete it as soon as possible. Where necessary stir the surface soil of beds planted with bulbs, so as to keep it open and friable, and also to give it a clean, neat, and fresh appearance. For small and suburban gardens, the white Arabis and the purple Aubrietia are very ornamental, especially for small rockeries. Fancies make showy border plants; Anemones may still be planted; all the species of Phlox are well adapted for these gardens; the Lily of the Valley will fill a shady corner; Pæonies are fine showy plants where there is plenty of room, but will not do well in very small gardens; *Geum coccineum* is a good plant for a small border, so is the yellow Alyssum, also the double Rocket. All the varieties of Pinks, and Carnations, and Larkspur, the variegated Monkshood, and Pentstemon gentianoides are very showy plants; the Canterbury Bell will flower in August, as also French and African Marigolds. In September, Dahlias, Salvias, Verbenas, and other half-hardy plants will furnish a constant succession of flowers. If planted in May, the common Fuchsia flowers the most of the summer and autumn. Asters and Chrysanthemums should not be forgotten for a late display.

### GREENHOUSE AND CONSERVATORY.

Proceed as diligently as possible with the repotting of

such of the hardwooded greenhouse plants as require it, so as to afford them every chance of making a vigorous growth. Be careful, however, before potting to have the ball in a nice moist state, and avoid giving large shifts to weakly growers. Endeavour to keep the newly-potted specimens together as much as possible, keeping the house rather more close and moist than usual. See that softwooded plants, as Pelargoniums, Cinerarias, &c., are allowed plenty of space and kept perfectly free of insects. Give air freely on every favourable opportunity, but do not allow cold winds to blow over them and disfigure the foliage. Let the occupants of the conservatory-beds and tubs receive that attention which is demanded by all greenhouse plants at this season, especially in regard to the supply of fresh soil and other necessary stimulants to active growth. Mandevilla suaveolens, the Kennedias, Passifloras, and Bignonias will require regular supplies of water, and, possibly, further supplies of rich mould. While the variable weather which usually characterises March continues, attention must be directed in these structures to maintaining a uniform and moderate temperature. The heavy showers and boisterous gales which frequently occur at this season, succeeded by intervals of mild weather and brilliant sunshine, render some management necessary. Fires should be dispensed with as much as possible. On still nights the houses may be damped and the syringe used, avoiding the plants in flower. Soil containing a considerable portion of decomposed vegetable fibre must obviously be more suitable for dwarf-growing plants, the natural habit of which leads us to suppose that such soil, existing on the surface of the earth must form, from its being readily available to them, their congenial and natural food.

## STOVE.

Proceed with the repotting of such plants as require it, and give all necessary attention to those in active growth. To secure strong short-jointed wood, keep up a vigorous root-action, and let the plants occupy a place as near to the glass as possible. Ixoras, Clerodendrons, and Allamandas that have become well rooted, will be greatly benefited by a careful supply of clear manure water, but see that it is given in a tepid state, and not over-strong.

## PITS AND FRAMES.

Keep a nice growing heat to the cutting frames, and if the linings are becoming cold, turn them to the bottom and add some well-fermented dung.—W. KEANE.

## DOINGS OF THE LAST WEEK.

## KITCHEN GARDEN.

WATCHED for an opportunity and sowed a piece of Onions and Parsnips, the rest of the ground not being sufficiently mellow for fuller or more general sowing. The Onion-ground was turned over, and when dryish well trodden, then raked, and shallow drills drawn about 12 inches apart, which were covered with fine rich soil, trodden, and raked, and a little soot and lime thrown all over. When the ground becomes dry will run a roller over it. This compression is good for the Onion at first, just to form the bulb and keep it near the surface of the soil. As soon as the Onions are fairly up the space between the rows will be kept slightly hoed with a Dutch hoe to keep clear of weeds and to keep the ground moist, without much loosening except at the surface. The depth to which the roots of Onions will penetrate in such circumstances is quite amazing.

*Celery*.—Ere long we shall take up with good roots the most of our beds of Celery, and pack the heads closely together with earth and ashes between them, that we may prepare portions of the ground for more Onions and other crops. Our Red Celery, Cole's Manchester Red and some other sorts, wants taking up, for if this is not done it will soon go away of itself, the tops having suffered severely; whilst those of the Dwarf White Incomparable, that received no more protection than the Red in time of frost, are as green and nice as if there had been no snow and frost to contend with. Sowed Celery in heat. For forward crops it should have been in the soil at least six weeks ago; but, after all, more depends on never stunting the plants after they are pricked off than in mere early sowing.

*Means and Room*.—Where the room under glass is to be

found for multitudes of things now, would puzzle the brains of a sage. It almost makes one envy those who have villages of glass houses, and who can procure coal from head quarters at so small a cost, that the value of a few extra shovelfuls need be no matter of consideration. Many of our great gardeners, and the proprietors of sweet little gardens, know but little of the shifts, and the cogitations, and the worries that many clever men experience when they find that there is never any boundary as to the expectations of extent and variety of produce, but a very limited boundary indeed as to means and room. We have known such cases as a man being up the half of the night, and often too, ransacking every possible place for wood, and cutting it up for his furnaces; and then being coolly told that he must be incompetent because he could not keep up the requisite heat in his houses, when there was no fuel to do it with. It was bad enough to be forced to make bricks without straw; but what if there had been no clay either? Some of the proprietors of small gardens may thus imitate those who expect very great results from the very smallest outlay; but in general they are alive to the fact that certain causes will only produce certain effects. Some time ago, a gentleman who had known what hard work was, when settling down in his beautiful villa, or box as he called it, wished us if possible to solve a problem which was giving him a considerable amount of uneasiness—namely, How it came about, that his gardener seemed to work hard, to be always at work, and ever and anon staying late to bring up his leeway; whilst the gardener in the next place, very similar to his own, and with the same amount of glass, some frames, a pit, a greenhouse proper, and a greenhouse vinery, seemed to be getting over his work very easily and quietly? It required no magic to find out the cause. Over the wall, the gardener was able to keep everything in its proper place. There was not a bit of cramming. The beds in the flower garden were few and thinly planted, with plants all standing primly potted in the houses, so as to fill the beds at some 18 inches asunder. A lady with a fair amount of crinoline could have passed through the houses without inconvenience. In our inquirer's garden, the greenhouse proper was clear as to its paths, but crowded everywhere else. There were four times more flower-beds to fill, and the gentleman liked to see his beds full of good plants some 8 inches apart. The vinery was crammed in consequence, floor, path, stage, suspended shelves—wherever a ray of light could be obtained. Early vegetables—as Peas, Cauliflower, Radishes, Beans, &c., were also brought forward in this house, so that generally, even as respects these common matters, he could have them at his table some weeks before his neighbour. In a dark place below the stage where no plants could do any good, was a Mushroom-bed that had furnished some nice pickings all the winter, protected from the drip from the pots by a piece of old waterproof-cloth. In watering, in moving, in coaxing such a number of things to be healthy in such little room, the gardener had actually more labour to perform than if he had had another house or two in winter and spring; and the same increase of labour was continued in hardening-off, planting, and tending such numbers of plants in beds, that were so good that the proprietor owned that few elsewhere, or anywhere, could beat them. He saw at once, that the little room for producing such abundant, diversified results, of itself did greatly increase the labour, and as he had no desire to go backward and be satisfied with less, he settled the matter with his conscience by considerably increasing the uncomplaining, hard-working, gardener's wages, and giving extra help when most needed.

*Peas and Potatoes*.—We are so far glad to get out of the glass-covered places to say that we planted a piece more of Potatoes where we can give them protection, and on a piece of the best-aired ground we have we sowed Peas and planted Potatoes. The backwardness of the season made us take this ground which we intended for another purpose; but if we do not obtain a first-rate crop of both Peas and Potatoes we shall be greatly disappointed. Last autumn it produced a heavy crop of Parsnips, Carrots, &c. The rich soil had previously been trenched down deep, and the poor and fresher soil brought up with a little of the subsoil, and this winter it was retrenched and ridged again, which brought some of the richer soil from the bottom to the top, and after being turned once or twice during frost in winter

the ground was in very good condition for anything. The Peas were sown in rows 10 feet apart, and three rows of Potatoes were planted between each two rows of Peas, the Potatoes being 3 feet from the Peas, and then the Potato rows 2 feet from each other. Some rows of early Peas were sown to prove so far what is said of them. As yet, for earliness and cropping combined, Sangster's No. 1 is our favourite. When well treated its produce is wonderful. At the outside we have sown the Tall Marrow, Jeyes' Conqueror or Ne Plus Ultra, the shorter, more compact, Veitch's Perfection, and the much smaller sort, but a good bearer and very rich flavoured, Harrison's Perfection. Of Potatoes the sorts were Early Frame, Ash-leaved, Early May, Early Shaw, &c. The Potatoes were in fine order for going out; but they would have been better had we had the convenience of wide shelves or shallow bins for storing them on until wanted for planting. A friend was boasting lately of what a fine sort of early Potato he had. He would astonish some of our old stagers, that he would. He had harvested them in a little barrel, and placed them in a snug warm place all the winter. On going to the barrel the other day he could not take a Potato out; they had grown into one impenetrable lump, so that to make anything of them he was obliged to knock the little barrel to pieces, and then the aspect of the strong long shoots was pitiable to behold. Kept cool and thin the Potato would have had plump shoots about an inch or less in length, and would have been a storehouse of vigour to support the shoot out of doors when the soil was warm enough to encourage it to lengthen.

Other vegetables much the same as in previous weeks. We found some stools of *Sea-kale*, very strong last season, on which the crown seemed to have rotted. In most cases shoots were breaking from beneath, but we do not like them so well as the strong prominent buds. We attribute this to want of protection during the very changeable weather of the winter—frost, snow, thaw, sleet, rain, succeeding each other in rapid succession; not but that *Sea-kale* is hardy enough in general, but the larger the tops above ground the more liable are they to the giving way of the crowns. A nice mound of ashes over the crowns, or even a little mound of dry earth in the autumn, would have saved this trifling miscarriage. We will shortly sow seeds under protection and transplant, as this will save them from the fly, which is apt to seize them when sown out of doors. Such seedlings well treated will do to force next season, and will be strong in the second season. Bits of the roots will also grow freely, but we prefer crowns with six or eight-inch stems to them or young seedlings.

#### FRUIT GARDEN.

Merely a repetition of previous weeks, with the exception of the *birds* that have attacked within eight days the buds of every fruit tree comeatable. Dusting, painting, dredging, &c., with nasty stuff and even netting seemed unavailing. As soon as the fruit-buds of Gooseberries, Currants, Pears, &c., swell and expand, out the heart goes, and often so quickly is a row done that you cannot see the deprecators. Our kitchen and fruit garden is bounded by stables, bushes of the pleasure ground, and farmyard, all right enough but for these terrible marauders, and even they are often useful except at the bud and fruit time. It is certainly disheartening when, after pruning, nipping, and fore-shortening in summer, you have nice little trees bristling with fruit-buds, and you find suddenly four-fifths of the best buds rendered useless and only a few small ones left. One evening, without getting leave exactly, a few of the garden lads batfolded some hundred dozen of sparrows and other birds from a few shrubs in the pleasure ground. Without desiring them any harm we do wish that those who advocate the use of these birds at all times and all seasons had a portion of our supply. In many places, where from covers all round, and where schoolboys must not peer into a hedge after a nest, fruit gardens out of doors will soon be unproductive if not securely netted all over before the buds of the fruit trees begin to swell.

#### ORNAMENTAL DEPARTMENT.

Out of doors we have done but little, as we had to collect a good quantity of tree leaves, which would have been done at once after the last pheasant-shooting, but for the snow and rains which rendered such work unsuitable; leaves col-

lected wet being both difficult to carry any distance, and to preserve even for a short time for heating purposes, as they cannot be kept from decomposing, whilst dry leaves can always be made to ferment by the addition of a little water.

Shrubby and herbaceous Calceolarias designed to flower early in pots, should now have their last shift using rich, rather light, sandy soil, but pressed firmly together, and as soon as the roots run into the new material, strength of bloom may be given by manure waterings. Pelargoniums intended for early flowering should now be tied-out, and if the leaves are too close thin them a little so that the light shall play nicely upon them, and for this purpose set the chief plants sufficiently thin. Much may be done in this way even in a house which is crammed, by setting smaller plants between the larger ones; or by elevating the latter on inverted flower-pots. Manure water as a rule should not be given until the flower-trusses are formed, after that the strength added will tell more upon them than on the foliage. Cinerarias, Primulas, Camellias, and even forced flowers coming into bloom will be the better of manure water but not given strong. Lily of the Valley, and all bulbs relish it as soon as the flower-spike appears. Azaleas to bloom late should be removed to a north aspect and kept cool; and, as said the other week, Lilliums, Tritonias, Ixias, Sparaxis, &c., should be watered and shifted as they require it, as soon as growth commences. We would, however, refer to other weeks as to many plants; and here only state, that if dull weather continue Neapolitan and other Violets in beds may be better of a slight dredging of sulphur and pounded charcoal, a little dry sandy soil being worked in among the plants to dry and improve the atmosphere of the enclosed pit or frame. Leaving such matters we will, to please several inquirers, advert to two modes of practice which have engaged our attention and time considerably during the week, and which relate to

*Planting Geraniums in Turves* instead of pots. First, "Our Geraniums, &c., stuck thickly in pots and boxes in the autumn, now want more room, and we have neither room enough, nor pots enough, to pot them singly. We fear to plant them out in an intermediate-bed as you do, and lift again after the middle of May for the flower-bed. How would it do to give the plants a little soil and wrap them in little bundles of moss, rough cocoa-nut fibre, &c.?" Tolerably well, but after considerable experience with all such modes, we think the timid cannot use anything better as a substitute for pots, than pieces of fibry turf. Thus, suppose, from the side of a road or an old pasture, you can take some turf 2½ inches thick, and in breadths of 1 foot. We place that turf where it will be gently dried a little and warmed, and we prepare, a little warmed, light, sandy soil, consisting of loam, sand, and very sweet old leaf mould. Then for stoutish plants of rooted cuttings, with a sharp knife we cut our turves longitudinally and transversely into pieces of 4 inches square, for less plants 3 inches square, and so on; and a clever handy lad will scoop out a round centre piece from each of these square turves nearly as quickly as he would crock a pot; just leaving a bit all round the side and not going quite through to the grass of the turf. A little of the nice mellow, heated soil is placed in the hole, the roots put in over it, a little more soil put over the roots and firmed as in a pot, then carried in sieves to their position, and watered with water from which the chill has been taken off. Now, as to the position. For quick work—that is, making small plants large ones, and to have the turf-pots bristling with roots all over, the best plan is to set these turf-pots on a little leaf mould over a hobbed, however slight, as that will increase the rapidity of the rooting and the growing; but in that case the turves must be lifted as soon as the roots come through them, and transferred to light soil in a cold pit, &c. If left long the roots would run through the bed, and the plants could not be safely turned. If taken in time to the earth-pit and the trench, the roots will progress more slowly, and when planting time comes, they will hang like a wig round their centres of turf. When planted turf and all together, they will run away into the well-aired soil, and thrive better than if they had come out of a pot with the ball unbroken. This is a good plan for all plants with straggling roots that will not lift well out of an earth-bed, as *Manglesii Geraniums* *Heliotropes*, &c.

The next best position and the best for strong plants that need no forwarding, and where less trouble is an advantage, is a cold frame or pit to which glass or other protection can be given. In this case a hard bottom must be secured, and a couple of inches of rough mould or other mould placed over it; on that pack the turves with their sides all but touching each other, water, strew a little rough soil all over between the plants, and besides protection and air when the sun is very hot, and now and then a dash from the syringe, such plants will need little or no watering or other care until they are taken with roots all through the turves and in the light earth round them, and transferred at once to the beds.

We meant to have followed with a few words on cuttings and potting, &c., but we must close for the present, merely stating that in a mild sweet hotbed cuttings of Geraniums, Calceolarias, Verbenas, &c., will strike in as many days as they will require weeks generally in autumn.—R. F.

COVENT GARDEN MARKET.—MARCH 18.

The supply of out-door vegetables is still very short; Sea-kale, Rhubarb, Kidney Beans, and other forced vegetables are quite sufficient for the demand. Pines are still scarce, and command a high price, but old Grapes are tolerably plentiful and still very good; new Black Hamburgs are also to be had at from 21s. to 30s. per pound, but the retarded Grapes being so good, are not in much demand; Apples are still abundant, but good dessert Pears are now chiefly confined to Beurré Rance, Easter Beurré, and Bergamotte d'Espereu. Consignments of Salads, &c., from the continent are well kept up, and include Asparagus, and Peas selling at about a guinea a quart. New Potatoes are to be had at 3s. 6d. per pound. There is a heavy supply of Cucumbers, but the demand for them being very good prices are fully maintained. Of Potatoes the stock is very heavy.

TRADE CATALOGUES RECEIVED.

Francis & Arthur Dickson & Sons, 106, Eastgate Street, and Upton Nurseries, Chester.—New and Select Agricultural Seeds.

G. White, 3, Moss Street, Paisley.—Catalogue of Florists' Flowers, Greenhouse, Herbaceous, and Bedding-out Plants, &c.

John Morse, The Nurseries, Dursley, Gloucestershire.—Catalogue of Cuttings of Dahlias, Fuchsias, Chrysanthemums, Verbenas, Pelargoniums, &c.

Ambrose Verschaffelt, 50, Rue du Chaume, Ghent, Belgium.—Prix Courant pour le Printemps et Eté, 1865. Plantes Nouvelles.

J. Bruce & Co., Hamilton, Canada West.—Descriptive Catalogue of Seeds for the Farm, Kitchen Garden, and Flower Garden, Roots, &c.

TO CORRESPONDENTS.

EARLY ASH-LEAVED KIDNEY POTATO (A Subscriber).—If by "chit" you mean eye this Potato certainly has not "a black" one, nor do we know any variety that has. Several emit dark purple sprouts.

SOILING CELOSIA SPICATA, PENTSTEMONS, AND SALVIA AZUREA (Contradiction).—Sow them all in pans in a compost of turfy loam two-thirds, and well-rotted leaf mould one-third, with a free admixture of sand, just covering the seeds with fine soil, and after watering place in a frame on a gentle hotbed. Keep the pans in the frame until the plants are up and have shown their rough leaves, then prick off into small pots, especially the first and last, pricking the Pentstemons into a pan—an inch or so apart will do. Continue the whole in the frame until the Pentstemons and Salvia azurea have made good growth, removing them, however, before they become drawn to a cooler situation, where they can be hardened off for finally planting out in the last week in May or first of June. If strong the Pentstemons may flower in autumn, they being hardy perennials, and the Salvia azurea will probably flower also, it being a half-hardy perennial. It should be taken up in autumn after the first frost, the roots potted, and kept rather dry during the winter in a greenhouse from which frost is excluded. The Celosia spicata seedlings should be repotted as soon as the roots reach the sides of the pots, and continued in the frame until May, when they should be removed to a warm greenhouse, or ainery at work, placing them on a shelf near the glass. When the flower-head is just visible in the heart of the leaves pot them in their blooming-pots, which may be from 6 inches in diameter for the small plants, up to 9 inches for the large plants. Employ the compost already named, with the addition of well-rotted cow or stable manure one-fourth of the whole. Provide sufficient drainage and keep well supplied with water, occasionally sprinkling the plants overhead with tepid water through a syringe. Continue near the glass in a warm greenhouse orinery, and when the pots are filled with roots every alternate watering may be of weak liquid manure, which will increase the size of the spikes of bloom. It is a highly ornamental plant for the autumn decoration of the greenhouse or sitting-room, and very useful for bouquets.

SMALL VINERY, VENTILATING AND PLANTING (Idem).—We do not notice anything in your arrangements to hinder your planting the Vines in front within the house, providing them with a border inside. We think that with the sharp incline of the roof the Vines would not do well trained down the sides from the back. It is not necessary to have front lights, there being no objection to there being none, nor to the sharp fall of the roof. The ventilation provided is ample. Six Vines, with two rows from each, planted 4 feet apart, the rods trained 2 feet apart, would be sufficient.

COTTAGE GARDENERS' DICTIONARY, &c. (B. H.).—You had better inquire of Mr. Eohn, the publisher, whether a supplement is intended; we have no interest in the work. We do not know the date of the last edition of Don's Catalogue, nor its price. Your Conifer is often called Cupressus aliformis, but it is now usually described by botanists under the name of Biota pendula. Lambert named it Thuja pendula, and Thunberg Cupressus pendula.

FLOWER-GARDEN PLANTING (S. G. W.).—As you ask our advice, we would be inclined to plant the wheel on both sides of the second terrace with the same colours. The Petunias will not harmonise with your other things in height, unless you have such a dwarf variety as the old small-flowered splendens. Each of these wheels consists of a circle for centre, and eight oblong beds round it. These beds may be made more artistic, and of many shapes; but your straight solid columns so many spokes will just look as well when planted as the most artistic scroll. The planting of the Day circle is with Heliotrope pegged down, and edged with Flower of the Day Geranium, the pegging being done not to intercept the view of the baskets raised on the third terrace. Now we have no fault to find with this; many adopt the pan; but we do not think that Heliotrope and Geranium make a good combination. We would then fill that bed with Heliotrope, and a broad edging of dwarf Ageratum, as you seem to have them; or if tall kinds, they could go in the centre, and be pegged down. In either case you would need no more blue. Better than that, we would prefer making the circle entirely of Flower of the Day, and the opposite circle of Alma or Lady Plymouth. This would give white either with or without the flowers of the Geranium. Then you propose to plant four of the spokes of your wheel—that is, each alternate bed with Cerastium. Two with Scarlet Verbenas, and two with Gazanias, would, we think, be making too much of a good thing of the Cerastium. Now though we like the Cerastium, we do not think it is quite right to have such large beds of it. With the centre bed white, a very simple arrangement would be to have these eight beds alternately filled with scarlet and yellow. They would also look very nice to be planted with scarlet, blue, yellow, and purple, the match or pair beds crossing each other. A very pretty arrangement would be to make the centre white-leaved Geraniums, as Alma, with the flowers removed, bordered with Lobelia speciosa, and then have four scarlet beds of dwarf Geraniums or Verbenas, edged with Cerastium, and four beds of a dwarf yellow Calceolaria, edged with purple Verbenas. This last would make each bed complete in itself, and you would have a beautiful contrast and shading of colour. You may use different tints for the two sides, but the more the two groups of nine clumps resemble each other the more pleasing they will be. We cannot quite make out about the raised bed or basket on the right-hand side, but we would decidedly use scarlet Geraniums instead of Cuphea for the centre. For the two four-tiered baskets we would do as you propose, but for the high central basket we would prefer a drooping Fuchsia, as Banks's Glory, to the Delphinium, or even such climbers on a rough trellis or the top of a tree as Murranda or Lophospermum. The edging might be Verbena pulchella. Your other arrangements on the third terrace will do very well.

STOVE AQUATICS FOR TAKE (A Lady).—These plants are grown by very few, the difficulty not consisting in the price, but where to meet with them. Nubium speciosum, N. jamaicense, N. Tamara, N. caspicum, and N. lutum; Nymphaea corulea, N. stellata, N. versicolor, and N. blanda; Heteranthera reniformis, Euryale ferox, and Villareia indica—these have floating leaves. Pontederia azurea, Alisma cordifolia, Jussiaea nansan, J. suffruticosa, J. repens, Herpestes stricta, Sagittaria angustifolia, Dama-sonium indicum, and Papyrus odoratus.

ACACIA ARMATA LEAVES YELLOW (Rather Puzzled).—The shoots enclosed in your letter are quite yellow, which might be occasioned by a variety of causes; but, in the absence of any data whatever, we cannot undertake to give an opinion. The roots are probably defective. There is, however, a trace of E.rips having been on the foliage, and they may have been the cause of the mischief. Fumigating with shag tobacco two nights consecutively, taking care to have the foliage dry, would extirpate them.

MISTLETOE SEED.—Mr. W. Gath, Bradford, Yorkshire, will be much obliged by any one sending him a few seeds of the Mistletoe.

ADDRESS (E. L.).—Messrs. A. & S., 571, Euston Road, N.W.

**CHARCOAL AS A MANURE (O. S.).**—We cannot answer you better than by giving the following:—Charcoal is a most efficient manure to all cultivated plants, especially to those under glass. Heaths, Rhododendrons, Cucumbers, Onions, Roses, orchidaceous plants, Hydrangeas, Camellias, Melons, and Fine Apples, have been the subjects of extensive and most successful experiments. We think no cultivated plant would be unbenefited by having charcoal applied to the soil in which it is rooted. It should be broken into small pieces about the size of a nut, and, for potted plants, may be mixed in the proportions of one part charcoal to twenty parts earth. If applied to the open ground, one-fourth of a bushel may be sown over a square rod or perch, and dug-in before inserting the crop. The reason of charcoal being so useful as a manure is very apparent. MM. Sennebiar, Saussure, and others, have demonstrated that plants are rendered much more luxuriant and productive by having carbonic acid applied to their roots, than other plants to whose roots no such application was made. Now charcoal kept moist, as when buried in the soil, slowly combines with oxygen, and emits carbonic acid—in fact it slowly dissolves. For drainage in flower-pots none better can be employed than 2 inches in depth of pieces of charcoal about the size of a fibret.

**CUTTING EXHIBITION FRUIT (Idem).**—The judges always cut Melons, as well as Apples and Pears, if needful to ascertain their ripeness and quality.

**STRAWBERRY FORCING (A Poor Amateur).**—1. The shelves shown at page 155 (Fig. 2), and styled Strawberry shelves in vinery, were intended to show the kind of house suitable for fixing the shelves, it not being intended to occupy the house with Vines and Strawberries at the same time—it is, indeed, impracticable; but if you do not start the Vines until April, you might have the Vines so contrived as to take out, and use it as a Strawberry-house from December to April, the shelves being put up in December, and taken down in April, after the crop has been gathered, and the Vines introduced, retaining a shelf, however, at back and front for more Strawberries. 2. The stage at back, beneath the shelves, is of no use for Strawberries, though useful to get at the shelves, and for plants after the shelves are taken down. 3. The earliest of all Strawberries is May Queen, it being ten days or a fortnight earlier than Black Prince under the same conditions; but it is a small fruit, though a great bearer. Black Prince, undoubtedly, would be the better for market. Perhaps the earliest and best for market is Keens' Seedling, which comes in about ten days after Black Prince, the fruit being large, and the plant a good forcer. The old Wellington is a very prolific and certain forcer, though the fruit is only small.

**TURF FOR VINE-BORDER (Idem).**—We laid up a heap of turf for a Vine-border in June, 1858, and turned it over twice, adding a bushel of soot and fresh lime to each cartload, and formed the border in autumn of three cartloads of chopped turf, one of brick and old mortar rubbish, and six bushels of boiled half-inch bones, thoroughly mixing the whole together. Unexpectedly we had two more borders to make ready by March, and we cut the sods 2 inches thick, and used them fresh, merely chopping them as they were brought, adding the old brick and mortar rubbish, and the same quantity of charcoal and half-inch bones. All the Vines were planted on one day, and there was no difference whatever in their growth. We have since used the turf a year old, but we find the older it is the worse for a Vine-border, which cannot be made too open, considering the length of time it has to remain undisturbed. Fresh sods, cut at a dry time, and roughly chopped, we like best, planting the Vines in a little fine rich compost, and making the border 9 inches or a foot higher than the required depth, to allow for settling.

**ALL SORTS OF PLANTS IN ONE HOUSE (B. W.).**—From the first part of your letter we thought you were going to give us an example of keeping everything in its proper place, and allowing nothing else to interfere with it in the way of the cramming that many of us have to resort to; but as we read on we found that, if you do keep flowers to themselves, you are not to be behind any one as respects cramming for fruit, when you speak of Strawberries, Vines, Peaches, fruit in pots, and Melons &c., in the same house. Now, all you propose doing may be done, and is done often; but compromises have to be made, and one crop must suffer frequently from attending to the wants of others. The great point is to get your Peaches in bloom, and set, before the Vines are scarcely broken, and then the increase of temperature that will suit the Vines when in bloom, will just suit the swelling Peaches. As the Peaches approach maturity, the greater quantity of air required for flavour will be too much for the Grapes, so that, though the Grapes will be very good and sweet, they will not likely be so large as if grown in a house by themselves. Our first advice, then, would be to keep one house for Vines and another for Peaches. You might plant Vines against the back wall; but neither they nor Peaches will do much good there, unless your stems of Vines, up the rafters, are at least 5 feet apart—that is if the Vines reach the top of the rafters. Then you might grow any sort of fruit, as Peaches, Figs, &c. in pots on the floor of the house, and move them so as to get what light and air and temperature would suit them best. By this plan you may grow any sort of Vines, giving Muscats the warmest end. Our second advice would be, if you will have Peaches in your early vinery, to confine them to the back wall, as there the greatest amount of air can reach them from the top ventilators; and to grow only the earliest and hardest Grapes, as the Black Hamburg, Buckland Sweetwater, and Royal Muscadine, and, for Muscat flavour, the White Frontignan. Bear in mind that the Peaches will thrive only as you keep the roof of the house thin of Vines. Or—third advice would be, if there must be mixture, to confine the Peaches chiefly to the late house, and have some early ones in pots, which could be moved from the vinery. In this case we would have a trellis in front, and trees against the back wall, and keep the Vines thin up the rafter—say from 4 to 6 feet apart. For this late house the same hardy Vines may be used, or, if you contemplate keeping them late, a plant or two of Lady Downes' may be planted at the warmest end. Before the trellis, and the rafters are filled, you may grow any of the fruits alluded to on the floor of the house, and Melons will do well in pots over the hot-water pipes. It will be as well if the pots do not touch the pipes. Your description of the position is unfavourable. Everything else can be done under glass except giving the command of light; and if you cannot have the health-giving rays of the sun the south aspect will be of little avail. The arrangement of the houses seems to be very good.

**DISSIES ON LAWN (A Subscriber).**—There is no other mode of extirpating them than by having them grubbed out by the aid of a knife, and putting a little quicklime into the hole thus made. A little light soil should then be sifted over the surface, a sprinkling of Suckling seed sown, and then the roller passed over it.

**VEGETABLE SEEDS FOR BARBADOS (G. J. Nottingham).**—In the mountain districts any of our English kitchen vegetables might be cultivated if the cultivator had a moderate amount of judgment. On the low grounds Broccoli, Cauliflower, Kidney Beans, and Cucumbers, would be likely to endure the climate; but why not try all our usual kitchen vegetables? If they fail the loss will not be heavy.

**EXPORTING STRAWBERRY PLANTS—VINES FOR SUCCESSION (R. D.).**—Tie the plants in bundles as you propose, plunge the root ends in cocoa-nut fibre refuse, put moss over its surface, and lace it down firmly with string. We should put the whole in a box and use wire net instead of a lid, and have the box in a cabin or on deck. Use zinc labels, and write on them with the appropriate ink. There is no Grape more marketable, or less liable to failure, than the Black Hamburg, and it will keep up the succession you mention.

**SILVER TREE (H. H. H.).**—This native of the Cape of Good Hope is found there only on the eastern slope of Table Mountain. The Dutch colonists call it *Witeboom*, and botanists name it *Leucodendron argenteum*. It requires a greenhouse or conservatory for its shelter. Soil two parts heath mould and one part sandy loam, chopped together, but not broken fine; drain the pot well, and mix some pieces of charcoal with the soil. Keep it cool and the air dry, never syringe it nor put it out of doors in summer. Let the soil be moderately moist, but excess of water and dryness are equally fatal to the roots.

**LILIUM ATRATUM (An Old Subscriber).**—Any moderately rich lightish loam suits it. It is hardy, and the bulbs left in the border during winter require no other protection than 2 or 3 inches depth of leaves or cocoa-nut fibre refuse to be placed over them.

**HYGROMETER (Lex).**—Catgut is sensitive enough in showing the dryness and moistness of the air, but this is useless unless affixed to a graduated scale, whereby a comparison and estimate of the amount of moisture may be ascertained. The seed was lost; but the "Desert Pea" of Australia we believe to be *Cianthus puniceus*, and the cultivation is given in all gardening books.

**CARNATIONS (G. R.).**—You can have "Florists' Flowers for the Many" free by post if you send five postage stamps to our office, with your direction. We give this answer because you will find in that book far fuller information than we can here find space for.

**PEARS FOR A S.S.W. ASPECT (A Subscriber).**—All the Pears you have planted will do on the aspect of your wall except Glou Moreau, and we would recommend in its stead either Thompson's or Red Doyenné. Marie Louise we should prefer to Ne Plus Meuris, and Fondante d'Automne or Urbaniste to Jersey Gratioli. However, you have not seriously erred. The S.S.W. aspect is just the place for Winter Nells, and we anticipate you will have some very fine fruit from it. In speaking of walls use the term "aspect," and then no mistake can arise.

**TRICHOMANES SPECIOSUM FRONDS BROWNED (A Constant Reader).**—Judging from the appearance of the fronds sent, we think the case in which the plant is grown is not kept sufficiently moist. The atmosphere should be kept constantly humid. The compost should never be allowed to become dry; and if water were constantly dripping on it, free drainage being afforded, the plant would have a greater length of frond. Your keeping the atmosphere so dry accounts for the occasional appearance of the small black insects, which assuredly are thrips. These will be best got rid of by keeping the case more moist, sprinkling it with soft water, which has been exposed to the air, once or twice daily, or as often as may be required, in order to maintain a uniformly humid atmosphere. A slight fumigation with shag tobacco will assist in destroying this pest; but the fronds should have no water standing on them; and care must be taken that the smoke is not too strong, and that it is cool when it reaches the fronds. This Fern requires a very humid atmosphere, a fair amount of light, a little of the morning or evening sun, and fresh air, the fronds dying off in a close atmosphere. It should, therefore, have air by opening the case a little, not much, otherwise the dry air of the room will dry the atmosphere of the case too much, and be equally pernicious, and the condensed water on the glass should be wiped off in the morning; this will tend to keep the atmosphere of the case pure, and lessen the necessity for air-giving.

**PINUS MARITIMA AND P. AUSTRIACA ON THE COAST (Blackpool).**—These Pinuses do very fairly on land by the sea, and withstand the sea breezes better than any trees we know of. Yours is a very bad situation; but we would advise your giving the above-named a trial, planting more extensively if they succeed. They do so in many places, and are extensively planted on the east and west coasts.

**INK FOR ZINC LABELS (A. B.).**—Try that which we gave a recipe for at page 163 of our Number published Feb. 21.

**LONICERA AUREO-RETICULATA (A Regular Subscriber, Peckham).**—Your plant is all right. The young leaves are always like those you enclosed, somewhat oak-leaf shaped and green. The plant strikes readily from cuttings.

**ESPALIER APPLE AND PEAR TREES (A. W.).**—If the shoots be rampant and gross they may be cut back to half their length, but if of medium growth they need not be cut in so much. Some regard to the shape of the tree ought to regulate the pruning, and in espaliers, trained horizontally, it is better always to allow the bottom branches to be the longest. There is no difficulty in getting the upper ones to elongate, which they sometimes do to the detriment of the lower ones. Being planted only last year, it is not likely they will want severe cutting in this season; but another season they may possibly want checking a little at root and top; but when they once get into a bearing condition grossness of growth is more rare.

**BEDDING GERANIUMS SUITABLE FOR PLANTING TOGETHER (N. C.).**—We are sorry we are not acquainted with all the varieties you mention, but we hope they will flower with you before planting-out time, and enable you to judge of their colour. Of the kinds we are acquainted with in your list, Spiffire, Stella, Glowworm, Sir W. Wallace, and Admiration might go pretty well together as scarlets; the last-named one, being the strongest grower, might be in the middle of the bed. Rubens is a dull rose, but good bloomer. Ross Morn is somewhat brighter. Carmine Nosegay is a crimson, and is a great favourite in many places. Bishop of Exeter and Ossian are strangers to us. If you want to increase your stock, cuttings may be put in for some time yet, and these may still be tidy plants to turn out in May if they be kept warm, but there is no doubt but they would be better and larger if not cut. Usually the requirements of the case determine whether propagation should go on or not.

**CREEPERS IN STOVE OVER FERNS AND ORCHIDS (Orchidophites).**—We think you have put in more wires than are needed, but you are not compelled to use them all. Creepers with strong large foliage, like *Ipomoea Horsfallii* and *Pasiflora edulis* or *P. quadrangularis*, occupy more space than most of the *Jasminums* or *Hoyas*, but they can be trained to any reasonable condition. There is no question but *Orchids* and *Ferns* will thrive very well under such shade; the great point being to prevent the creepers darkening the house too much late in the summer when the *Orchids* want a little more sun. This you must remedy by thinning. *Bougainvillea* does best in a pot, the plant being exposed to the full sun. Let us know how Mr. Bewley's mode of glazing answers with you.

**GRAPE VINE BUNCHES BECOMING ABORTIVE OR TENDRIL-LIKE (Subscriber of Some Years).**—This is not an unusual occurrence, and is attributed to two causes—the imperfect ripening of the fruit-bud the preceding autumn, and the absence of sunshine to assist nature in her up-hill work of making the most of such bunches as are not entirely blind. We have little hope of any treatment now preventing the evil; but we may say that allowing the fruit to hang long after being ripe tends to weaken the Vine, as also does pruning too soon or too late, or a too-heavy crop, or perhaps the border lacked moisture, or had too much of it. All these and some other excesses tend to check the due development of the plant, and a failure is the result. Your present management seems all that can be done, and brighter weather will, we hope, assist in saving what is now left.

**ARRANGEMENT OF PLANTS AND FILLING STONE VASES (A Constant Subscriber).**—Arranging plants for effect on a greenhouse stage is a matter difficult to understand, unless the operation was performed in the presence of the person wanting such information. Of late years plants with remarkable foliage have entered largely into plant arrangement, and fresh ones are added every year, and as we do not know your particular wants we may say, that in the staging of plants, allowing one now and then to rise above its fellows is a good plan, providing always that such as show

themselves above the level are well grown and handsome. The filling of large stone vases may vary each time the plants are changed, which, we presume, is pretty often for in-door purposes; as the plants may simply be plunged, pots and all, and covered with moss, in our case we often have creepers prepared for the purpose of hanging over the edges, and tall and medium-sized plants for the centre. A trailing *Tradescantia* is one of our greatest favourites for a marble vase, but *Isolepis gracilis* and several *Ferns* are used occasionally. Possibly one of our contributors may give us a list of plants available.

**GARDENING NEAR THE SEASHORE (Marina).**—If your situation be a favoured one, and not likely to be reached by the spray from a cold boisterous quarter, you may plant several kinds of shrubs, with a fair prospect of success. *Laurustinus* thrive well in such places—better than common *Laurel*; then there is the *Tamarix*, *Pinus Mugho*, double *Gorse*, and even *Sycamore* will endure a strong sea air. In fruits the *Peach* thrives well, as likewise do *Strawberries*; and amongst vegetables *Potatoes*, and the whole of the *Cabbage* and *Broccoli* tribe do well, as is shown in the large quantities sent to the London market from Cornwall, where they are grown mostly within a mile of the shore, and often within a stone's throw of it.

**NAMES OF FRUITS (Rev. H. W.).**—The two small red Apples are *Scarlet Nonpariel*, and the large paler one is *Dumelow's Seedling*.

**NAMES OF PLANTS (R. F. M.).**—We do not recognise the scrap you sent. (*Notice*).—*Chondrus crispus*. A common pocket lens will answer your purpose. It may be had of any optician. (*Col. D.*)—Apparently an *Arbutus*, but we cannot be sure without seeing the flower. (*R. P. B.*)—Your Mosses are—1, *Bryum hornum*; 2, *Dicranum scoparium*; 3, *Polytrichum piliferum*; 4, *Hookeria lucens*; 5, *Hypnum muscoides*; 6, *Tortula muralis*; 7, *Bryum nutans*; 8, *Funaria hygrometrica*; 9, *Weissia controversa* (or *W. trichodes*?); 10, *Hypnum proliferum*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending March 18th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY-KEEPING FROM A COMMERCIAL POINT OF VIEW.

It is for Englishmen to determine whether England is capable of profitably supplying eggs and poultry for her own consumption, but I am painfully surprised to notice how very few seem to take an interest in the subject, which you have been pleased to bring before your numerous readers with laudable zeal and perseverance. When I had the honour of addressing you in No. 204 I was in total ignorance of the highly interesting discussion raised by Mr. Geyelin, whose ability and industry entitle him to public sympathy and support, at least to the extent of fairly trying if it be commercially possible for England to feed her own people. He goes very fully into figures to show this may be profitably done. Some few, and I regret to say but very few, of your numerous correspondents seem to notice his remarks, though none can doubt their importance. This is not very creditable to the poultry amateurs of England, who are ever ready to discuss most zealously and learnedly about the breeds of fowls, or the proper colours of cock's legs and tails, but who seem to ignore such practical dry business details as the produce of hens and the cost of feeding them.

These are mere questions of detail, and resolve themselves into a matter of £. s. d., but the success of Mr. Geyelin's project depends entirely on the amount and cost of production and the market value of the produce.

It is not for me to interfere between Mr. Geyelin and "C. S. J.," so I leave them to settle as they can, for it is evident both mean well though differing considerably in their views. I must, however, notice two correspondents in No. 206, one "AN OLD SUBSCRIBER," on the wholesale price of eggs, the other "BARNDOR," on poultry food and annual egg produce. Both are apparently adverse to Mr. Geyelin's figures, but in point of fact neither seems to affect him in any way.

His scheme only refers to London prices, and to the productive powers of hens fed and lodged so as to stimulate the utmost powers of production. It is but fair to Mr. Geyelin and the public to use the utmost candour and sincerity so as to put the case fairly. He fixes the produce of hens fed on his plan at 180, while "BARNDOR" writes, "Cochins, Brahmas, &c., should lay 120 eggs in a year." True, but how many more may be reasonably expected? Does "BARNDOR" give this as the actual result of his own experience? If so, will he say how the hens were treated, their ages, &c.? I admit the mere opinion of one man, or even his practical experience, can carry but very little weight; I can, however, quote some well-known authorities which fully sustain Mr. Geyelin's calculations about the produce of hens, while but one goes so low as 120, the figure of "BARNDOR," for the best known egg-producing breeds. Cobbett says eleven hens should give 2000 eggs and 100 chickens, if well fed, in one year, and allows eighteen bushels of barley to feed them with one cock. Richardson relates that three Polish pullets laid 524, cost 16s. 6d. Baxter records that four hens laid 710 eggs one year at a cost of £1 2s. 1½d., and 594 the next year at 15s. 9½d. In the work called "Farming for Ladies" we read, "Hens lay nearly all the year round, except when moulting and in the depth of winter, but generally speaking at least ten to twelve or fourteen dozen eggs a-year may be counted on." I dare say the experience of most of your readers will differ quite as much as that of those writers, so much depends on the peculiar circumstances of each case. In my opinion a fair average can be taken only by the actual results obtained by a large number of the most careful breeders, who keep their poultry in the best and cheapest way. I am in candour bound to add that in "Chambers' Information for the People" it is broadly laid down that no hens will pay for their food if it is all purchased.

This question is strictly a national one, for it is most important to ascertain by actual experiment if eggs and poultry may be produced by ourselves as cheaply as by various nations immeasurably behind us in everything relating to agriculture. If Mr. Geyelin can succeed in teach-

ing Englishmen that this may be done, then few will deny his claim to be fairly considered a national benefactor. At present his task is not an easy one. As it is really the duty of every well-wisher of his country to aid this noble effort by every practical means, so your experienced readers should each contribute so far as he can to simplify this question by clearing up the doubts and difficulties that surround it. Men are naturally timid and shy of embarking their money in any novel experiment of which they have but very scanty knowledge, and which of us can say that he has any knowledge of thus producing eggs and poultry commercially in England? For the present I shall say nothing about the little animal which is well known to be a decided commercial success in Belgium, where many are largely engaged in breeding, feeding, and exporting to hungry, wealthy England the—OSTEND RABBIT.

#### MR. DOUGLAS AND THE GAME BANTAMS AT MANCHESTER.

I DID not attend the Manchester Exhibition, but I received a letter from Mr. Fielding, in which he stated that Mr. Douglas had claimed the first prize pen of Game Bantams, and that the birds were offered to me for £10. I authorised Mr. Fielding to purchase the pen, but at the same time observed that a judge acted improperly in claiming birds at a show. The money, less a sum due to me from the Islington Show, was remitted to Mr. Douglas by Mr. Fielding. I highly disapprove of anonymous accusations, and recommend "A TIMID EXHIBITOR" and "HE WHO RESOLVED THE BANTAMS" in justice to all parties concerned to communicate their names to your readers.—ST. GEORGE GORE, *Hopton Hall, Wirksworth, Derbyshire.*

#### EXTRA PRIZES FOR PARTRIDGE-COLOURED COCHIN-CHINA FOWLS.

HAVING read the letter of Mr. Tomlinson, in your Journal of the 14th inst., respecting extra prizes for Buff Cochins at the next Birmingham Show, and being as enthusiastic an admirer and breeder of Partridge birds as he is of Buff, I beg to suggest that similar prizes or one or two cups, say for old and young birds, be given to Partridge Cochins; and I have much pleasure in subscribing £2 in furtherance of this object, trusting that other Partridge breeders will do the same, and at once send their subscriptions to Mr. Lythall, Birmingham.—EDWARD TUDMAN, *Ash Grove, Whitchurch, Salop.*

#### DISTINCT VARIETIES OF PIGEONS.

It is with pleasure I respond to "WILTSHIRE RECTOR'S" request as to my opinion respecting the distinct varieties of our domestic Pigeons. I write "varieties" because the word "race" seems to me to be too uncertain of meaning, and when explaining our ideas we cannot be too particular as to the words we make use of. I consider that all our domestic Pigeons are descended from the Wild Rock Pigeons, and, consequently, are all of one species; but these Rock Pigeons, even in a wild state, present us with slight variations, which have been designated as sub-species or geographical varieties. These are the Blue Rock with white rump, the Blue Rock with blue rump, the Blue Rock with chequered shoulders, and the chequered Dovehouse Pigeons—variations slight indeed, but such as have been considered by naturalists to constitute only geographical varieties and not distinct species. These varieties of Blue Rocks having been domesticated in different countries and their offspring becoming crossed and mixed has given an impetus to sporting or greater variations, which, under the fostering care of man have been wonderfully increased and developed, sometimes by accident, at others by careful selection. Through many successive ages have the variety of domestic Pigeons arrived at their present state.

All tame Pigeons are therefore supposed to be of one species. But there are very many varieties. Let us take, for instance, the variety with wattled beaks, of which, the

Persian Carrier (closely resembling our Dragoons), is probably the original, or, at least, the oldest known example; it has been bred with longer beaks, as in the Scandaroons, Bagdads or Horsemen, and with shorter beaks, as in the Barbs. The English Carrier is the last or newest sub-variety of the Wattled variety. I believe it to be admitted that the English Carrier is essentially a high fancy bird, and produced from a cross from Persian and Bagdad Carriers with a dash of Powder. The sub-varieties may therefore be regarded as the various branches of one family; they all bear a striking family likeness, and yet differ much in size, form, length of beak, &c. As to colour of the plumage, that may be influenced and altered at will, leaving so little appearance of any admixture in other respects, that a bird can hardly be said to be of another sub-variety, because it is of a different shade or tint. Black seems to be the original colour of this family or variety.

Next as to Fantails. Here we find white as the original plumage of this family or variety; and, as in the preceding, we have several sub-varieties, as the Indian with long necks and point-headed; the German, with shorter necks and turned crowns; the French Silk Fantails, and our graceful English broad-tailed Shakers. Various colours are in the Fantails of much more recent introduction, black and blue not being uncommon. No doubt they were first produced by a cross, but if well up in the requisite points of the variety are so much the more valued by fanciers.

As to the colour of the eyes, the dark hazel is common to all white Pigeons, the difficulty is to breed a white Pigeon with any other. All the wattled Pigeons just alluded to, when they come of white plumage have dark eyes; but dark Pigeons have light eyes. I remember a curious blunder in this respect among the stuffed Pigeons in the Prince of Weid's museum, where the white Fantails were stuffed with pearl eyes, and some other dark breed had received their dark eyes. Coloured Pigeons, or such as have coloured heads, as a rule have light eyes. Sometimes white Tumblers have pearl eyes, but they are difficult to breed; and I have at this time an excellent breed of white Tumblers, many of which tumble from thirty to forty times in a minute, that have just that deep hazel iris and black pupil which "WILTSHIRE RECTOR" alludes to. In parti-coloured birds, as Almonds, Baldheads, and Beards, it is the aim of the fancier to breed the Pigeons with pearl eyes, but they well know the proneness of such birds to breed broken eyes; and in many of the Toys, where the division line of white and colour passes through the eye, such birds often have the eyes half and half, that touching the white plumage being hazel or dark, while that part next the coloured feathers will be gravel. I do not therefore lay much stress on the colour of the eyes; that I believe to be influenced by the plumage in our domestic Pigeons. I have no doubt but that all varieties were originally of a certain colour, and that of that colour they were best; but fancy often changes, and better birds after a time may be had of quite a different colour, so much depends on cultivation.

The purity of varieties is so very different to the distinctness of different species that the two will hardly bear comparison. Many of our choicest breeds of Pigeons and poultry are so crossed either accidentally or intentionally, that absolute purity of variety is a thing more easily talked about than proved. If individuals of some desired form or colour are selected and bred carefully for three, four, or more generations, the offspring will generally come pretty nearly alike; and I suppose this is what some persons allude to when they call this, that, or the other a pure breed or a distinct race—terms more easily said, I think, than explained. Generic or specific distinctions are very different. They are limited by nature, and the mixture of species generally produces barren mules.—B. P. BRENT.

A VERMIN TRAP WANTED.—We beg to direct attention to an advertisement in which the Royal Society for the Prevention of Cruelty to Animals offer a prize for an improved vermin trap, which shall either, without inflicting torture, secure vermin alive or instantaneously destroy them. There can be no doubt that much unnecessary pain is inflicted by many of the contrivances at present in use, when it becomes

necessary to check the too rapid increase of destructive animals; and it is to be hoped that the inducement offered by the Society may be the means of calling forth an invention fulfilling the conditions laid down; we will also take this opportunity of saying that this Society is most praiseworthy in all its proceedings, and every way worthy of support.

### BEEES IN LANARKSHIRE.

POLLEN-CARRYING commenced here on the 24th February, although I saw young bees (Ligurians), as early as January 26th; and February 9th being rather a mild day most of the hives got well aired, and a great many young bees were seen, so that, what with early breeding and fertility, it augurs well for their future prosperity.

The hint respecting strange bees killing the queens of other hives will still be fresh in the minds of some of your apiarian readers. The stock of which the queen was killed has remained queenless the whole winter, and the bees have been wonderfully preserved, being the most crowded hive in my apiary. I was unwilling to lose it, and therefore obtained two weak hives from a friend who was unable to bring them through the winter. One of these queens, which I gave them on the 10th of February, was well received, and this stock since threatened the destruction of several hives by robbing; and although the Ligurians could protect themselves well enough, still it prevented their going abroad in search of dollen, and not a single hive escaped.

I may here mention that it is not all profit to have hives over-strong, unless all in the apiary are about equal, as the warfare, when once begun, seldom ends till some have fallen victims. I generally deem it best to remove the strong stocks; but in this case I lessened its strength by taking part of the bees and uniting them to one of the queens above referred to, whose bees were all dead. Having presented the queen to them, she was immediately imprisoned, and would not have been allowed to survive had I not interfered. I then caged her and put her in the hive, but the bees deserted her, and it being too cold to leave her alone, I freed her, and tried her with them again, but still the same spirit reigned. I again captured her, and having kept her in my hand for a short time, again presented her, when in an instant a strange Ligurian darted furiously at her, and nearly stung her. I thrust it off, but only for a second attack, when it seized her by one of the legs. I then killed it; but, so tenacious had been its hold, that, after fifteen minutes, the queen was still dragging the Ligurian about. This clearly demonstrates that strange bees attack the queens of other hives.

All this time I had not been able to effect a union. There was no time to lose, as the bees were fast leaving; nor would they receive her till I applied a drop or two of essence of peppermint, diluted with a little syrup. I first smeared the queen and then the bees, and in an instant the union was as complete as it was interesting. I have now made two hives from one, with plenty of bees for both, and restored peace in my apiary, having them now all in their spring dress, which is a covering of soft dry grass round each hive, to promote breeding; woollen cloths I detest as harbouring moths.—A LANARKSHIRE BEE-KEEPER.

### TAKING HONEY IN CENTRAL AMERICA.

READING of taking honey in Assam in your Number of the 7th inst., reminds me of taking honey in British Honduras. There, however, precautions are not needed, the honey bee having no sting, and being, so far as I recollect, the only insect in that unpleasant country without a weapon of offence and a strong inclination to use it. The Indians (Asteques) are sometimes employed in the mahogany-cutting works, and their fondness for honey makes them take every nest they can. All the nests I saw were in hollow trees. The Indians having found them (and to find them requires pretty sharp eyes), cut down the tree, and having sounded it with their axes, would cut it open where they found the nest to be. The honey was very clean and good, the combs were

not hexagonal, but shapeless, like the cells in an ant's nest. The wax, in comparatively large quantities, was taken by the Indians to make candles of. The bees were small black ones and stingless. We met with others, by no means stingless, but got no honey from them.

It may interest some of your readers to hear that in the centre of the large hanging ant's nests the Indians found a mass of white grubs which they said were as good as honey to eat, but I confess I had not courage to attempt them. Once I believe I did eat some at an Indian festival, thinking they were sweetened rice, but my companion found out what they were, and I could not persuade myself to try their taste again.

If I had known anything about orchids I might have written plenty about them, as Guatemala abounds in them, but, unfortunately, I was as ignorant of them then as I am now. Should I ever find myself there again I will try and be more useful to the readers of THE JOURNAL OF HORTICULTURE.—V. G. C.

### DRIVING BEEES TO AVOID THE WAX MOTH.

SINCE last writing to you I have lifted the hive referred to off its floorboard. In the feeding vessel I found several maggots and also a live moth of a grey colour and full of life, but it was thrown into the fire; the former I have sent for your opinion.

Having a nucleus box, half filled with honey and combs, I purpose driving them into it at once before the queen commences laying, and so rid them of the plague.—T. S.

[By driving the bees into a nucleus box at this season you will destroy more brood than you fancy, and very probably do the stock irreparable injury. Better have patience until fine mild weather set in, and then transfer both bees and combs to a frame-hive as directed in page 442 of our third volume, when the extirpation of the moths will become easy. The maggots accompanying your letter are larvæ of the wax-moth.]

### STEWARTON HIVES.

If your correspondent Mr. Raynor would apply to Mr. Paton, joiner, &c., Stewarton, Ayrshire, he could obtain an abundant supply of boxes.

The boxes need not be confined to 4 inches, but can be made to order of any depth. I have seen boxes used 6 to 8 inches deep, principally for "body boxes" and sometimes for honey boxes on strong hives. Bees can easily be hived in four-inch boxes by putting two together. With a nice roomy bee-house and Stewarton hives, the most nervous and unskilful may manage successfully without getting stung or killing a bee.

The Stewarton bee-keepers in favourable seasons take two crops of honey, one off the clover, and the second off the heather, to which they transport the bees several miles. The first crop is considered the best. A four-inch box, when full, weighs about 20 lbs., and sells at from 2s. to 2s. 6d. per pound.—P. M.

### OUR LETTER BOX.

STORING EGGS (*An Amateur*).—There is a difference of opinion, but we always stick the small end of each egg downwards in a shallow box of sand.

PIGEONS IN CONFINEMENT.—Can I successfully breed and rear first-class healthy fancy Pigeons in a large spare room without allowing them to fly out in the air? Of course a window can be kept open and covered with wire.—F. T. H.

[You can keep them well in that room. Most of our best fancy Pigeons are bred in rooms. Mr. Eaton, of 37, Red Lion Street, Clerkenwell, London, E.C., has published a diagram which will assist you to fit up the room.—B. P. B.]

BOOK ON POULTRY (*S. W. C.*).—It is in preparation, with coloured plates, and will appear early in the summer. We can give no further information at present.

GAPES (*J. Skinner*).—Chickens so affected should have a piece of camphor daily, given them as a pill about the size of a pea. Put also a piece of camphor in their water. Give them also daily a little bread soaked in ale.

BUYING BEEES (*A. B. C.*).—We cannot give you the information you require. Advertise stating how many stocks you need.

GLAZING AN AQUARIUM (*G. G.*).—We always use white lead.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 54.7°, and its night temperature 43.6°. The greatest heat was 73° on the 3rd, 1848; and the lowest cold, 16°, on the 1st, 1833. The greatest fall of rain was 1.19 inch.

DAMPING-OFF AND MILDEW.

**NO**WING that the preservation of bedding-out plants during the winter months, especially Geraniums, Verbenas, Lobelias, &c., is a matter of very general interest to nearly every class of your readers, I

venture to forward you a few remarks upon two of the greatest difficulties which have to be contended with during the dark days of winter—that is, damping-off and mildew. It is hardly right, perhaps, to class the two together, as they do not always proceed from the same cause; and certain classes of plants, such as Verbenas and Roses, are more liable to mildew than others, whilst Geraniums, which are very apt to damp-off during the winter, are rarely, perhaps, attacked with mildew.

I will begin with the damping-off of plants, which I think owes its origin more than anything else to defective root-action. It is a very generally-received axiom, and one which is confirmed by almost every book on gardening that one takes up: Keep your plants as dry as possible during the winter. Now this rule misleads amateurs or unpractised gardeners more, perhaps, than any other, because they forget that very essential proviso, that the plants are only to be kept as dry as is suitable to their health. There are many persons who withhold water from their plants just the same in whatever position they may be placed, whether on shelves, stages, or on the floor of the house, and again make no difference between a house heated by hot-water pipes, a flue, or hot air. Now all these points ought to be carefully borne in mind, because a Geranium in a large pot on the damp floor of a cold vinery, with just sufficient heat in the hot-water pipes to keep frost out, will, perhaps, remain in a healthy state all winter without any water; whereas young autumn-struck plants of Geraniums on a shelf in a house heated by a flue, and kept near the light and air, may require water every two or three days. Very often it happens that Geraniums are left on stages unwatered for many days after their leaves have begun to flag, and till the balls of earth have become so dry that when they are watered all the water passes down the sides of the pots, leaving the balls as dry as they were before. The consequence is all the young rootlets perish, and then, if a week of damp unless weather set in, the leaves, which had begun to droop from want of moisture at the roots, will eventually damp off from not being able to breathe—in short, they are no longer capable of performing the functions of vegetable life; and though, perhaps, in the case of a Geranium, the plant may be able to push some few young

leaves, or some of the young leaves may not have suffered as much as the old, still it too often ends in the death of the plants. When once the young rootlets are killed it is of no use supplying water to the plant, as it will not make fresh roots till the return of spring, or till it is put into a warmer atmosphere, or gentle bottom heat.

Now what is thus fatal to a Geranium is still more fatal to a Verbena, a Lobelia, or Calceolaria. With respect to the latter, nearly all your readers must know that it will more readily stand excess of moisture and cold than of heat or drought; there are no plants, therefore, so easily kept through the winter by means of a cold frame, and which require so little care as Calceolarias; but I have often heard complaints of Lobelias damping-off, whereas they will withstand almost as much cold and moisture as a Calceolaria, but require rather more ventilation; and far more plants, both of Lobelias and Verbenas, suffer from excessive dryness at the roots than from wet.

During bright frosty weather and moonlight nights, when it is necessary to keep fires constantly going, the air of a greenhouse becomes exceedingly dry. No doubt plants can resist frost better when they are dry than when the atmosphere of the house is charged with moisture, so that as a general rule it is not wise to water plants late in the day so as to have the floors and stages wet when all is shut up for the night. But if it be true that plants can stand more frost when they are dry, it is equally true that frost will less readily penetrate a moist atmosphere. I have raised the temperature of a house, 25 by 14 feet high in front and 13 at the back, and all surrounded by glass, except the back wall, from 40° to 44° in a very short time on a frosty night, merely by pouring water into the openings of the hot-air flues, the house being heated by a hot-air apparatus; and where houses are heated by flues (which are apt to dry the air too much), evaporating-pans placed on the top of the flues, and a slight syringing of the sides of the flues, will not only help to give a more healthy atmosphere to the plants but will materially aid in keeping frost out. Where stages and paths are wet the evaporation only produces cold, but a little water on heated flues or hot-water pipes helps to raise the temperature.

I have hitherto said nothing about mildew. This is no doubt the growth of a fungus on the leaf or stem, but what first causes the fungus to grow and how many different kinds of fungi there are which we commonly know by the name of mildew is a far wider question. Mildew is seen under extremely different circumstances, but I think is generally caused by defective root-action, the roots not being able to supply the sap fast enough to the leaves, or sometimes from the leaves being in a higher temperature than the roots. Verbenas and Roses suffered very much last year in the early summer, especially in dry soils and sunny places, and it would seem as though mildew attacking healthy young Rose shoots exposed to sun and air in the open ground must differ very much from the mildew which attacks plants in cold damp houses in the winter, and yet I am still inclined to

think the cause is much the same. There is no more certain cure for mildew on Roses in summer than a thorough soaking of water at a temperature of 80° or 90°. "UPWARDS AND ONWARDS," I think, speaks of liquid manure heated to 140°. This seems a severe measure, but if the plants do not suffer from their bath I have no doubt it would effectually check the mildew. In either case, however, the remedy is owing to the roots being excited so as to give a more abundant supply of sap to the plant.

When a mildewed leaf is examined under a microscope a fine reticulated white substance like inspissated sap is seen to stand on hair-like tubes quite above the leaf; it can be scraped off with the point of a knife, leaving the cells of the sap-vessels of the leaf flattened. I cannot trace any cellular formation in the mildew, the white substance seeming more like sap which had escaped from the leaf, owing to the leaf being punctured by the root of the fungus. I should like to know whether any of your readers who have a microscope with very high powers have ever been able to trace the different parts of the fungus.

Any check to the sap predisposes, I think, the leaf to the attack of mildew, and the best way to avoid it in winter on Verbenas and other plants is to keep them steadily but constantly growing, and to have a thorough circulation of air round the plants. Wooden stages, with plenty of air between the bars, and hot-water pipes or flues underneath, with the outer air coming directly on the heated pipes through openings in the front wall, so as to create a thorough circulation and yet to have the air heated before it ascends, is about the best way to succeed with Verbenas; and it is much better to put the plants into a hotbed for a fortnight in the spring and let them make young wood before taking their cuttings, rather than to try and strike the tops which have been on all the winter; no time is lost in the end, as there is as much difference between striking fresh quick-grown cuttings and old ones as there is between striking the old wood of Calceolarias and young shoots.—X. Y. Z.

#### THE LATE MR. F. CHITTY.

MANY readers of THE JOURNAL OF HORTICULTURE, who have, in common with myself, read the interesting and thoroughly practical articles on general gardening, written by the late Mr. Chitty, will feel that his loss to the lovers of horticulture will not easily be replaced, and all must feel deep sympathy for the bereaved widow and helpless children of such an estimable man.

The letter from his employer in last week's Number of THE JOURNAL OF HORTICULTURE, proves how well he was beloved by his personal friends, and how much he was respected and esteemed by his employer.

What a lesson this teaches both to employers and employed! and how forcibly does it illustrate the advantages to be gained by both, when there is such a reciprocity of feeling as this existing between an employer and his gardener. What a large amount of pleasure it would bring to the employers of labour in all its various branches, and what a degree of happiness and contentment it would bring to the hearts of those whose bread is gained by the labour of their hands, if this feeling of reciprocity was more widely extended. On the part of the employer of labour, the feeling would be one of confidence instead of suspicion and mistrust, and on the part of those employed content, happiness, and a keen appreciation of their master's worth. This would lighten the burden of their daily toil, and the constant wishing for the time to leave off work, thus prolonging the day, and the habit of leaving many things undone, and doing that which is done in a careless and slovenly way: this would be removed by the desire to do all in their power to make a suitable return for the respect and confidence reposed in them. The mind would thus be so intent upon, and absorbed by the duties of the day, that the fast-fleeting time would not be noticed. Man would, therefore, return to his home at the close of his day's toil, in the happy consciousness of having done his duty to his employer, and with the satisfaction of having omitted nothing necessary for the attainment of the object of his labour.

Let us all, then, try to emulate the good examples set before us by him who has gone from amongst us, and by his

worthy employer, who still lives to do justice to his late servant, and to be a comfort and help to his widow and fatherless children; and let us hope he may long live, and be the means of inducing many employers of labour, with whom he may come in contact, to follow the example he has so nobly set.

I enclose a small sum, from myself, foreman, young men, &c., employed in the gardens at Oulton Park, for Mrs. Chitty, and hope all gardeners will respond to the appeal so kindly made by Mr. Webley, in behalf of Mrs. Chitty and her bereaved family, and show that they are, as a class of men, not insensible to the cause of the widow, and the cry of the helpless.—J. WILLS, *Oulton Park*.

[A list of subscriptions received since our last issue will be found among the advertisements on our sixth page. We have more which we will acknowledge next week.]

#### MR. BATEMAN AND THE CHISWICK GARDEN.

ALL of us interested in gardening must feel a high respect for the name of the gentleman at the head of this article, so well known is he as a patron of the science. In botany in the path he takes he is an authority, and in gardening with the same qualification he is to be looked up to; but an experienced general horticulturist, after his remarkable speech at South Kensington, we cannot consider him.

Alas! that we are not likely again to see at the head of the horticultural world a man like our once revered President T. A. Knight. "We ne'er shall look upon his like again!" I have been led into this train of thought by carefully reading the assertions of Mr. Bateman in his speech of February 14th, so very carefully reported in the "Proceedings of the Royal Horticultural Society."

Mr. Bateman commences by saying that "Chiswick is in a most efficient state," "making due allowance for the change of circumstances in the horticultural world." I am most willing to allow that Chiswick in its limited way of doing things is in good order; not a shadow of blame can be cast on the superintendents, but, then, how poor and trifling as a grand national experimental garden is everything there. I am often compelled to tell my foreign friends who make inquiry for our public garden where horticultural experiments are carried out, that we have no such garden; for Chiswick with its small and inefficient houses, except that extravagant folly, the conservatory, now a vinery, has nothing in it worthy of the notice of gardeners either foreign or English.

The "changes in the horticultural world" are all changes for progress, and not the mere keeping in good order an effete garden. I remember in old times, some thirty or forty years ago, the keen enjoyment I used to feel at Chiswick, only because it was then in advance of the age—it ought to be equally so now; and when we look at the enormous sums that have been squandered in the last few years by our Society one cannot help feeling deep chagrin that we as gardeners have nothing to show but a poor gaudy place all brick and stone, and an experimental garden without experiments.

There are no "impossibilities" in the way, as stated by Mr. Bateman. "The change which is taking place in the aspects of horticulture" calls for a change, and a great one, in our should-be national garden, so as to make it worthy of the present day. The changes in it ought to have advanced step by step with the gardening knowledge of the times, so that at this moment we might be able to show the whole world how much we are in advance of all the nations upon earth.

After enumerating three points in which Chiswick is eminently useful, commencing with, "first of all an experimental garden," Mr. Bateman passes to his fourth consideration—the Chiswick Shows. We all well remember their great popularity; their decadence was not owing to "rivalry, emulation, and competition," but solely to bad management—a lack of the *suaviter in modo*—a lack of skill in arrangement—a lack of that active superintendence which an efficient Council ought to have given; but there seemed no activity in it; all was left to one or two, who were overworked, and required the guidance of good and wise men,

and so the fall came. Chiswick at this moment ought to be the one fashionable flower show near London; its distance is an advantage, for whereas the Regent's Park Gardens would take off the great crowd of London sight-seers, Chiswick, with the price of tickets wisely arranged, ought to be the resort of the *élite* of society, not probably to see the exhibitions, but to meet the pure *crème de la crème*, and I have not the least doubt but that the "Chiswick Shows" might have been kept up to the present day if an active and wise Council had taken proper measures; but as far as I remember there was some adverse influence hanging over the Society for many years. The Council seemed inert, active men were kept out, and those that by some mistake were admitted were always outvoted; and so the Society kept "mooning" along till debt overwhelmed it, then came that ever-to-be-lamented sale of the library, and ruin, so far as the objects of the "Horticultural Society of London" extended. All that Mr. Bateman states about the decline of the exhibitions at Chiswick, and their being left "in consequence of rivalry" to the genuine votaries of horticulture, too few to "make them pay," is a mistake.

With regard to "another respect in which the garden was eminently useful—as an arboretum." I can only state from my knowledge of hardy trees and shrubs, which with, perhaps, some little presumption, I am inclined to place nearly on a level with that of Mr. Bateman, that if I were a nurseryman and wished for a site near London, on which to cultivate Coniferæ, Rhododendrons, shrubs of the order of Ericaceæ with a little assistance, and all the evergreen shrubs and trees and fruit trees known in our gardens, I should select Chiswick. The fertility of the soil is remarkable, and the slight assistance it requires to make hardy trees and shrubs flourish, has been to me for these thirty or forty years past a marvel. We have only to look at the coniferous trees in Mr. Glendinning's nursery, at Chiswick, in the immediate neighbourhood of the Gardens, to see at once how mistaken Mr. Bateman has been in his consideration of the present state of the Chiswick Garden. It is true that some few of the trees suffered severely in 1860, from which they have scarcely recovered; but no injury to the trees from the smoke of London can be discovered. With regard to the rivalry of Kew, that is *par excellence*, the people's garden; but Chiswick should be *our* arboretum, full of arboricultural beauty, and, above all, quiet, owing to its visitors being select and lovers of the science. As to the soil which Mr. Bateman abuses, I have always found the loam, spreading over the thirty acres (not twenty), reckoned deep and fertile. Where can be found a finer border of Peach trees, or trees managed more perfectly? Where do Pear trees flourish better? And where do kitchen garden crops succeed better? All these crops show plainly that the soil is not a "poor gravelly soil."

In my opinion, in which I am not solitary, it is not "childish to talk about reviving the horticultural interest of Chiswick." Far from it, for with only a small portion of the extravagant sums of money spent at South Kensington, well-spent at Chiswick, it might be, and ought to be, at this moment the pride of the horticultural world.

We now come to the third point discussed by Mr. Bateman, the introduction of new plants and trees. What valuable opportunities have been lost within the last twenty years! While our northern neighbours were organising societies for exploring the north-west coasts of America, whence they introduced so many valuable trees, and while collectors were gathering seeds for private persons of that grandest of all coniferous trees, the Wellingtonia, which alone would have redeemed the failing prospects of the Horticultural Society of London, the Council, apparently effete and lifeless, calmly looked on. Then within these few years came Japan with its invaluable stores of trees and shrubs, brought to us by private enterprise, without the least attempt on the part of the Society to be first in the field. When one considers these lost opportunities, one can scarcely believe that a horticultural society in this rich country could have been in existence at the time. With energy and money properly applied, what an arboretum might have been formed at Chiswick, not only in the open air but under glass; for if light roomy structures had been built—not such massive extravagant houses as the "great conservatory," but light, strongly-built, reasonably-priced, unheated glass structures—many Himalayan trees and shrubs, and all those from

Japan, might have been now in full luxuriance, and a pattern to the whole gardening world, which at present is little aware of the extreme beauty of what are called half-hardy trees and shrubs when grown in unheated houses, and even of many that are hardy enough to stand our winters, but requiring more heat in summer to fully develop their beauties, and this they can only have under glass. Now, experiments of this kind, of the highest interest to all who have a cultivated taste, should have been carried out by the Society at the Chiswick Garden, making it the pride of the country.

With respect to the fourth point in Mr. Bateman's address, I am most willing to acknowledge that a fair collection of varieties of fruit exists there, but not beyond that in the hands of others in this country. The distribution of scions for grafting, which that experienced horticulturist Mr. Cole says, "was never more fruitful than it is at this moment," and which the intelligent audience greeted with "hear, hear," is a small redeeming point in the doings of the Society. But how small, how insignificant, how odd, that only one little "ha'porth of bread" should be found worthy of a cheer in a very long apogetic address! Yes, there was another "hear, hear" when Mr. Bateman alluded to the Chiswick of the present and the past. A few words will correct the sophism uttered. The Chiswick of the past was before its day; the Chiswick of the present is behind its day.

As to the *lapsus lingue* respecting the dearth of "eminent practical horticulturists," it was of course only a slip for which Mr. Bateman is doubtless very sorry, and he will of course in due time apologise. The next slip is so full of burlesque and so ironical, that no wonder it was received in deep silence. *La voila*, "If any gentleman has any horticulturist in his mind more profoundly versed in the mysteries of the science than any members of the present Council, he has only to mention his name, and he will be elected by an overwhelming majority." Now just imagine one or two of the old Fellows selecting half a dozen good sound practical gardeners and men of business, and recommending them to the Council for election! What a mustering would there have been of Fellows and Fellowesses to assist in keeping them out. Mr. Bateman should not have made the assertion. Why, I could have pointed out a dozen or a score of good and true men, "more profoundly versed in the mysteries of the science of gardening," than any member of the Council, not forgetting one who has been a good practical gardener.

I regret to find that Mr. Bateman in his apology for Chiswick has omitted to mention the education of gardeners, which ought to be now in progress. Several eminent men last year lent their aid to concoct a scheme by which Chiswick would have been a centre of education and registration for gardeners, so that any gentleman requiring a gardener could at once go to the centre of gardening for one. Instead of this being promptly and fully carried out, it seems that "arrangements are being made" for gardeners to undergo an examination in botany by the Society of Arts. How unworthy of an old-established Society! This seems a sort of "shifty" policy that one cannot understand. Just imagine the Geographical Society, for instance, making arrangements for their neophytes, if they had any, to undergo an examination by the Linnæan. A powerful Society like the Royal Horticultural ought to do its own work.

As regards botany it is very agreeable, although not essential, for one's gardener to know the rudiments of this rather loose science. Surely it must to a certain extent deserve the name, for its professors have hitherto made it a point to agree to disagree; still, arrangement and classification are necessary, and a gardener with an intuitive taste for it, after knowing its rudiments, may make himself a proficient, but as a general rule a good gardener does not make a good botanist, nor a good botanist a good gardener; they are distinct species of the genus *homo*, and both good and useful, the former a man of active energy, the latter a man of quiet persevering research.

I have now gone over Mr. Bateman's apology for Chiswick, I can give his earnest speech no other designation, and, in common with most of the old Fellows of the Society, regret there being any occasion for it. Allow me now to state how our old favourite garden should be managed.

One good clever gardener should be there to give his undivided attention in carrying out experiments on a far different scale to the present. Some enlightened accomplished gardener should be on the Council to suggest such experiments, and to see them carried out, so as to put at rest all theoretic culture, and enable the Council to say to the gardening world, Come to Chiswick and see. I could, and I would if I thought there was the least chance of their being carried out with energy, give a list of horticultural experiments of great interest still untried; but while our Society has that millstone round its neck—the gardens of South Kensington—nothing of the kind can or will be done. I see no remedy for this state of things, unless the Royal Horticultural Society ceases to fritter away its time in giving certificates for music, sculpture, table puerilities, Primroses, Violets, and Wallflowers; or to form a National Horticultural Society. I have no wish to be hasty, and I shall continue to pay my four guineas annually till a society of true earnest lovers of horticulture can be inaugurated to show to the world what can be done by English gardeners when properly directed.—F.R.H.S.

#### LA CONSTANTE STRAWBERRY.

WHEN I was a Harrow boy, I used to go to London on a Saturday, to visit my relative, the Hon. Mrs. Agar, at 1, Dean Street, South Audley Street. Her son, Mr. Agar Robartes, the present Member for Cornwall, was also a Harrow boy. With him I went to London. On one occasion I went to Astley's, and saw acted the then famous "Tom and Jerry," and also the "Invincibles." On another occasion I went to Drury Lane, or Covent Garden, and saw a play acted, which convulsed everybody. Roars were excited by the announcement, "Here's Monsieur Tonson come again!" Well! here's La Constante come again! and I am one of the "Invincibles!" I do not want the last word, but Mr. de Jonghe, unintentionally of course, has not exactly "resolved" my statements. I refer only to the first. The others I admit. I never said La Constante was not hardy in the sense he intends you to understand—namely, that it will not stand the cold of winter. On the contrary, your readers will remember that I stated it was suited to clay lands, and a northern aspect. It was not here *summer-hardy*.

Mr. de Jonghe's offer is a very fair one, and I hope amateurs (it would not succeed with the generality of *quasi* Strawberry-growers), who have good land and take pains with Strawberries, will give it a trial.

I received a letter from Mr. Turner concerning a new seedling of Mr. Bradley's, in which he says, "My experience confirms Mr. Radclyffe's respecting La Constante; but those who differ may be right, as far as their experience goes. Different soils and situations have a great effect on some kinds. I cannot get rid of the impression, that it is a variety that will not remain very long in our collections."

I believe I sent it both to Mr. Turner and Mr. Rivers in the first place, having every desire to see it propagated in this country. I told them at the time, after my experience of it and great pains, that it did not suit me, but that it would, probably, suit their finer lands. I sent it also to Mr. Taylor, who lives in the fine vale of Mowbray, hoping that it might suit him. He has not had it long enough to be sure about it. It may yet turn up well, when put in early enough. It is, however, in any land strictly an amateur's Strawberry. It is not a Strawberry plant that can be recommended to go into all lands and all hands. No one can have read the statements made by the defenders of La Constante without perceiving that the efforts have been laborious, and the pleading "special." I remain a member of the "Invincibles," and promise, unless evoked, not to act again the part of "Monsieur Tonson."—W. F. RADCLYFFE, *Tarrant Rushton, Blandford*.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—At a meeting of the Committee held on the 20th inst. it was resolved that an election of three pensioners shall take place in July next. It was also resolved that the anniversary dinner shall take place on Friday, July 7th, on which occasion Jas. R. Jeffery, Esq., of Woollen Hall, Liverpool, will take the chair.

#### LIVERPOOL SPRING FLOWER SHOW.

THE flowers! The flowers! The stars that gem our earth, even as the stars themselves are the flowers of the sky! Who does not love the pretty flowers at all times and all seasons? beautiful as they are in the dewy morn of summer, and the calm eve of autumn; and if possible, still more beautiful and engaging, not only by contrast, but by all the delightful associations of promise and of hope, amid the frosts and the snows of winter, and the rude surly blasts of spring. Such, as we were permitted to read them, we feel convinced were the prominent sensations that passed through the minds of the more than three thousand visitors, who happily promenaded among the tables and banks of floral loveliness in the noble St. George's Hall, at Liverpool, on the 15th March; the fine proportions of the gorgeous Hall itself, and its rich artistic finish and embellishments, being for the moment lost sight of amid the attractions of some fifteen hundred entries and collections of plants, embracing such a blaze of Azaleas as reminded one of May and June, the dense masses of rich Rhododendrons, the many gaudy-coloured Tulips from a thousand bulbs; and not only the striking contrasts in colour, but the sweet fragrance that loaded the atmosphere, from more than seven hundred Hyacinths. And as if it were not enough that the organs of sight and scent should be gratified, the ear was regaled with beautiful music from Mr. Harrison's band in front of the grand organ, and during the interludes a splendid thrush made the arched roofs echo and re-echo with thrilling and plaintive notes, causing us to feel as if we were surrounded with choirs of the sweetest songsters of the "woodlands wild."

So far as we could make out in casual conversation, there are two horticultural and floral societies at Liverpool, which are severally independent of, but which act rather in unison with than in anything like opposition to each other. The one holds its exhibitions chiefly in summer, and is so far patronised by the Corporation as to be permitted to hold its *fêtes* in the Park close to the Botanic Garden, which at that time presents features in the new style of flower gardening hardly to be rivalled elsewhere. At these times and only then, as we understood, visitors to the Botanic Garden are allowed to traverse the beautiful lawns. At all other times visitors as a matter of necessity are confined to the broad handsome walks. The other Society, of which this is the third season, holds its *fêtes* early in spring and late in autumn; and though it boasts distinguished patronage on its prospectus, it is well known that it was chiefly set on foot to meet a felt want, by Mr. Tyerman, the much and generally esteemed manager of the Botanic Garden, ably assisted by Messrs. Ker, as Secretaries, and a Committee of nurserymen and gardeners connected with the immediate neighbourhood.

The decided success which this latter Society has already achieved, and the increased stimulus it has given to the culture of flowers for spring and autumn decoration in the western metropolis, have been so great that it might be advisable to merge in the management, not only cultural skill, but the enthusiasm of the amateur, and the matured judgment of men of business. We can well understand the anxiety felt on such occasions by those who sustain the chief responsibility, and who can receive no reward for their efforts but the consciousness that they have at least endeavoured to extend the range of knowledge and of happiness. We may differ much as to our estimate of true greatness, and may even regret that some called *great* have but too truly left their "footprints on the sands of time;" but we can hardly differ as to our estimate of the self-denying efforts of those who are quietly leaving their marks on human hearts, by opening up new fields of investigation, and pure fresh sources of enjoyment amid the contemplation of the beautiful.

On entering the Hall the effect was very striking, though with the same materials it might have been made much more so without any confusion as to the separate classes. To this we may refer before we conclude. Suffice it to say that the arrangement left nothing to desire so far as bringing the competitive plants in each class at once under the eye of the Judges. Immediately in front of the orchestra, and beneath suspended baskets, a long circular stand was filled with beautiful bouquets, and we would suggest that in future the awarding of the palm of honour should be left to a

chosen committee of ladies. The difficulty for any man to decide in the matter arose from the simple fact that they were all so beautiful. Ladies did award the nurserymen's prizes here, and Mr. Cutbush, of Highgate, and Mr. Rylance, were the successful competitors. There were at least a dozen bouquets in the best taste, and of the richest materials. We hope the ladies satisfied themselves, and if they did they far outshone the gentlemen judges. The decision among amateurs and gardeners at length rested quite as much on a matter of style as of intrinsic merit. The first bouquet was centred with a fine white Camellia, raised well in the centre, surrounded with a band of flowers of blue Hyacinths, slightly dotted with Maiden-hair Fern and the crimson flowers of *Euphorbia jacquiniæflora*, and then a broad band of white and red Roses, bordered with flowers of white Fuchsia and a little garnish of Maiden-hair. The second was one of some half a dozen in the flat style made of the rarest Roses, *Stephanotis*, &c., relieved by Mosses and Ferns, and decorated with lace. The third was very pretty though of simple materials. The centre was considerably raised, consisting of a circle of flowers of red Hyacinths, from which went four spokes or lines of red to the circumference, which again was formed of a rim of red and pink Hyacinths. This left four spaces to fill, and two of these were filled with bands of blue and lilac Hyacinths, and the two others opposite each other with flowers of the white Hyacinth; some Maiden-hair, &c., was used as garnishing. The successful competitors were for first and third Mr. Lythgoe, second Mr. Turner. We have been led on to this as it will suit several correspondents, but we have strayed from the description of the plants. These nosegays alone, so numerous and so good, gave an idea of the floral treasures of the district.

On the lefthand side from this orchestra end, a bank of Azaleas ran the whole length of the Hall, and on the right-hand side a bank was filled with Rhododendrons, and other plants. The centre of the room was occupied with three tables, with wide spaces for visitors between, that on the lefthand side was chiefly filled with fine-foliaged plants, Primulas at the sides, Narcissus, and fine pans of Lily of the Valley. The central table was wholly filled with Hyacinths at the sides, and bush and standard Mignonette in the centre. The other table was filled with Tulips and Cinerarias, and the end opposite the orchestra had some fine single specimens of greenhouse and stove plants, &c.

Leaving a correct list of the prizes to the Liverpool newspapers, we will just take a glance of the prominent features, with such running comments as may be useful and interesting. And first, of Azaleas, as perhaps, the most prominent feature in the Show, the first prize was taken for six small, bushy, compact plants sent by Mr. Sorley, gardener to Zwilchenbart, Esq., consisting of Duke of Devonshire, Elegans, Exquisita, Coronata, Dilecta, and Fielding's White; the second prize was taken by the same grower for plants very similar; all the twelve being dense, low bushes, as wide as they were high, and mostly concealing at least one-half of the pot. The third prize was taken by Mr. Williams, gardener to C. Mozley, Esq., and contained good large plants of Empress Eugénie, Præstantissima, Queen of Whites, &c., but they were not so well furnished at the base as the smaller and younger plants. In three Azaleas, the plants were very fine, and here Mr. Williams took first and third; Mr. Wood, gardener to F. W. Medley, Esq., second; and Mr. Sorley, third; and extras were given deservedly to Messrs. Turner and Leadbetter. For single plants, the first prize was given to Mr. Williams, for a large broad-based plant densely loaded with bloom; second to Mr. Lythgoe, for a dense massive plant of Apollo; and a third for a fine plant to Mr. Orr, gardener to H. Pierce, Esq.

For forced hardy plants, the first prize was taken by Mr. Morris, gardener to W. D. Holt, Esq., for well-bloomed plants of *Weigela rosea*, *Deutzia gracilis*, Rhododendrons, and hardy Azaleas, and second and third were taken by Mr. Leadbetter, chiefly for Azaleas and Rhododendrons. Passing from this bank and along the end of the Hall, we come to the single specimens of stove and greenhouse plants, the first prize being given to a fine plant of *Acacia Drummondii*, a mass of yellow flowers, growing in a pot about 14 inches in diameter, and we should judge the plant to be about 6 feet in height, and the same in diameter of head. The

second was a *Bletia Tankervilleæ*, with eleven spikes of bloom; and the third was a barrel-shaped *Rhynchospermum jasmuinoides*, the scent of which would have been more telling, but for the perfume from the Hyacinths. On the righthand corner, first and second prizes were taken for standard Roses in pots, by Mr. Maunderson, gardener to H. Jones, Esq.; and for dwarf Roses in pots, prizes were taken by Mr. Maunderson, Mr. Hignett, and Mr. Wood. Here, too, a prize was awarded to a fine-grown plant of the double-flowering Peach.

For six stove or greenhouse plants, the prizes were taken by Mr. Dunbar, Mr. Williams, and Mr. Wood. Besides good Azaleas, the first gentleman had neat plants of *Pimelea Niepperiana*, and *spectabilis*, an interesting plant of *Acacia longiflora magnifica*, *Eriostemon buxifolium*, and *Franciscea confertiflora*. Mr. Williams had fine plants of *Adenandra fragrans*, with pinkish bloom heads, and that rather troublesome plant, *Boronia serrulata*, in a robust state. The bank of Rhododendrons was nicely in bloom, and the prizes were well divided, but there did not seem anything remarkable except a light variety, *Rhododendron præcox*, a hybrid raised by Mr. Davies, of Larkfield Nursery, Wavertree, and said to be very suitable for early blooming, whether forced or not.

We have now arrived at the orchestra again, after passing several baskets, such as are used for flat packing-baskets in nurseries, some 3 and 4 feet in diameter, filled with plants in bloom. Two or three of these were done with much elegance and taste so far as the flowers were concerned, but others were pitched or tumbled in, to look more natural we presume, and certainly they bore little traces of art; and in one case only did we notice any attempt to hide the rough unpeeled sides of the willow baskets. We would recommend all such rough baskets to be dispensed with in future, and to substitute for them neat baskets of a definite size, to be filled with plants in pots, but the pots all hidden, or to be filled with cut flowers; and if all the boxes or baskets are of one defined size, we have no hesitation in saying, that if the same taste is exercised upon them as upon the bouquets, the place in their vicinity will be as crowded and impassable as it was round the nosegays.

The hanging baskets, though seemingly much admired, were a failure, simply because one set were filled with Hyacinths with their upright growth, and the others seemed a great variety of things stuck into wooden Orchid-boxes at random. Hanging baskets ought to have drooping plants dangling from them. To compensate for these suspended baskets in front of the orchestra, and separating the bouquets of the gardeners and amateurs from those of the nurserymen, were some stands of cut Camellias, which deservedly received a great amount of attention.

Having thus walked round the outsides, we come now to the three long tables, the first filled with fine-foliaged plants, Primroses, Narcissus, Lily of the Valley, &c.; the middle table with Mignonette, as bushes and standards, along the centre, and the sides with three plants at least in depth, of Hyacinths in pots; and the third table on the right was filled with Tulips on one side, and Cinerarias on the other.

Taking this outside table first, we would say that the Cinerarias were very passable, but much behind the fine Azaleas and Rhododendrons. The Tulips, however, were very fine, and gave the table a noble appearance. Here, among nurserymen, Messrs. Cutbush, of Highgate, took first and second prizes, for twelve pots of double, and twelve pots of single Tulips—that is, for thirty-six plants of each, there being three bulbs in each pot, and not less than six varieties in each collection. As affording some information to those proposing to force these plants next season, we here give the list of the varieties of double Tulips thus exhibited:—*Rex Rubrorum*, bright red; *Gloria Solis*, brown, crimson, and yellow edged; *Overwinnar*, crimson and white; *Yellow Tournesol*; *Golden Yellow*; *Duke of York*, rose, with white border; *Tournesol*, Red and Yellow. These were first. The second lot also had *Overwinnar*, *Gloria Solis*, *Yellow Tournesol*, *Duke of York*, *Tournesol*, and *Imperator*, crimson.

The following are the first twelve single Tulips:—*Duchesse de Parma*, brown, crimson, and orange; *Cramoisie Superbe*, crimson; *Fabiola*, violet and white; *Couleur Cardinal*, scarlet; *Alba Regalis*, creamy white; *Grand Duc*, yellow and crimson; *Cottage Maid*, rose, pink, and white; *Vermilion Brilliant*, scarlet, fine; *Roi Pepin*, fine white, crimson

flakes; Cramoisie Royale, red and white; Proserpine, rich rose; Keizerkroon, rich yellow and red.

The second twelve were as follows:—Cramoisie Superbe, Keizerkroon, Fabiola, Grand Duc, Couleur Cardinal, Vermilion Brilliant, and Proserpine, as above; to which were added—Duchesse de Parma, crimson and orange; Duc d'Artemberg, brown and yellow; Pottebakker, white; Rouge Luisante, fine rose. The very repetition of the kinds by one of the most eminent growers, will give a good idea of the best sorts for early work, and this will farther be promoted by noting the lists of such exhibitors as Mr. Paul, at Regent's Park and Kensington.

Fine collections of Tulips were exhibited by Mr. Maunderson, Mr. Williams, Mr. Sorley, Mr. Dunbar, Mr. Mossdale, &c., but the bulk of the kinds will be found in the above lists. We noticed besides showy specimens, among doubles, of *Imperator Rubrorum*, large red; *Marriage de Ma Fille*, red and white striped; *La Belle Alliance*, purple and white; *Lord Wellington*, singular dark lilac.

The collections of bush and standard Mignonette on the middle of the central table had been good, but were mostly past their best, and might be full of flower in a few weeks hence. The magnificent show of Hyacinths was here the great attraction. Among Nurserymen Mr. Cutbush again bore off the prizes of first and second for twenty-fours; Mr. Grey, of West Derby, second with good plants; Mr. G. Davis, Old Swan, third; and extra prizes to Messrs. Davies, of Waver-tree. Mr. Cutbush's collection of twenty-four pots that took the first prize, were as follows:—*Grand Lilas*, azure blue, large; *Princesse Clothilde*, pale pink and carmine, large; *Charles Dickens*, grey blue, large; *Macaulay*, deep rose; *Princess Charlotte*, rosy shaded pink; *Marie*, purplish blue, indigo stripe, fine; *Argus*, blue with white eye, fine and striking; *Alba Maxima*, fine large white; *Garrick*, dark blue; *Baron Von Tuyl*, dark blue; *Grandeur à Merveille*, pale blush; *Snowball*, pure white, large bells, new and dear; *Von Schiller*, salmon pink; *Haydn*, lilac mauve; *Mimosa*, purplish black; *Van Speyk*, pale, striped with dark blue; *La Prophète*, pale pink and carmine striped; *Maria Theresa*, pink and red; *Florence Nightingale*, pink and carmine stripes; *Mont Blanc*, fine white; *Mrs. Beecher Stowe*, fine pink; *Bleu Aimable*, violet shaded with blue, fine; *General Havelock*, deep purple, very fine; *Queen of the Netherlands*, fine, pure white. In the second twenty-four *Princesse Clothilde*, *Argus*, *Grand Lilas*, *Charles Dickens*, *Queen of the Netherlands*, *Macaulay*, *Mont Blanc*, *La Prophète*, *Mimosa*, *Grandeur à Merveille*, *Haydn*, *Mrs. Beecher Stowe*, *General Havelock*, *Van Speyk*, *Marie*, and *Florence Nightingale* were repeated; the fresh ones being as follows:—*Laurens Koster*, dark blue, fine; *La Dame du Lac*, rosy pink; *Emmeline*, blush with pink stripes; *Gigantea*, fine deep blush; *Duke of Wellington*, rose, with carmine stripes; *Lina*, bright crimson; *Lord Palmerston*, greyish blue with light eye, good, like *Argus*; *Von Schiller*, salmon pink.

These collections were distinguished not only for good spikes on the whole, but good-formed bells, and dense enough to conceal the stems, which proceeded from among short stiff foliage, that showed the bulbs had been encouraged to do their best, without leaves and stems being drawn or enervated by heat. As fine individual flowers could be found in plenty, but these collections above were very good and regular throughout. Among the plants of Mr. Davis were good specimens of *Von Schiller*, *Prince of Orange*, rose, striped and shaded with orange; *Lord Wellington*, *Mirandoline*, fine white; *Latour d'Auvergne*, pure white, &c. In the extra awards, among other fine spikes were extra good specimens of *Howard*, orange crimson; *Homerus*, dark red; *Alba Maxima*, fine white; *Baron Rothschild*, dark red; *Albion*, dark blue; *Anna Paulownia*, a fine blush, &c.

Very fine collections of Hyacinths were also exhibited by gentlemen's gardeners, as Messrs. Cahill, Hignett, Williams, Dunbar, Wilson, Sorley, Lythgoe, Turner, Fleming, &c. Among the sorts not mentioned above were fine specimens of *Cavaignac*, salmon with rosy stripes; *Seraphine*, fine pale blush; *Ida*, fine yellow; *Alba superbissima*, worthy of the name, &c. Were we to go in earnest into Hyacinths, we should like to have every one of these named, with an additional dozen from every celebrated grower of his best kinds.

Let us not forget we may also mention that there were some

beautiful Hyacinths that had been grown in water, some very strange flowers of some kind of *Arum*, that we could not obtain the name of some nice showy plants sent by friends to fill up, a very neat plan of a flower garden, with the colours arranged, and a nice box of black Grapes, sent by Mr. Meredith, that had a very fresh appearance, and the berries covered with bloom. We understood that they had been cut from Vines in 12-inch pots which had been started into growth on the 14th of January, 1864, and though thus fresh, they had been ripe more than eight months. We presume it was *Kempsey's Alicante*.

We have now glanced at all except the long table in front of the Azaleas, filled with fine-foliaged plants, which were very creditable without affording anything very striking; with *Polyanthus Narcissus*, which pleased more by their vigour and delightful scent than by their variety; also with nine shallow pans of *Lily of the Valley*, over which some ladies hung in raptures, and the first three of the nine being extra good, and well worthy of the first prize awarded; and last of all, with a fine lot of single *Primulas*, the most of which had been better a month ago, and the finest appearing in very small pots. The double *Primulas* were also showing signs of exhaustion from free blooming, but the first prize was given to fresh small plants, some of which seemed to be seedlings, and which were named *Delicata*, *Candida*, *Fimbriata*, *Atro-rosea plena*, *Rubra*, and *Old Double White*. Next the entrance end of this table stood a pretty silver-chased *épergne* with one elevated vase in the centre, and four smaller vases branching out at an equal and lower level; and these were so nicely filled with *Acacias*, *Camellias*, *Epacris*, &c., and wreathed into a light airy whole by means of pendent shoots and drooping Ferns and Mosses, as to impart the lesson that great elegance and pleasing effects may be produced in such circumstances in little room, and with but little variety and a small amount of material.

There are several things which this fête would bring forward as worthy of ventilation, but want of time prevents our alluding to more than the three following:—

1. Arrangement. The noble Hall has galleries at two sides and at one end, and from the latter especially a fine view was obtained of the whole floral display. From these points it struck us that the effect would have been more striking, if there had been a background of green branches or green baize, &c., to throw back the colours of the Azaleas, and the *Rhododendrons*, and if the three tables had obtained variety and irregularity, even as to height, by placing a thin row of the greenhouse and stove collections along their centre. Even the twelve standard *Roses* stuck up in a corner would have had a good effect on the centre table along with the *Mignonette*. Others may think quite differently, and they have a perfect right to do so.

2nd. A lesson may be gained as to the hours during which exhibitions in towns should be open to the public. We have known many once-flourishing societies come to grief, and end in loss and bankruptcy, at least be unable to meet their liabilities, and chiefly because the public were admitted only for a few hours in the afternoon. Mr. Tyerman and his *confères* are wiser in their generation. *St. George's Hall* was open on the 15th, from 1.30 P.M. to 10.30 P.M., and the crowded state of the Hall and the galleries during the evening, the well-dressed and well-behaved people being scarcely able to move along and obtain a view of the flowers, in which they seemed much interested, proved incontestably that the system is a good one. It ever seems natural to associate the flowers of earth with the still sweeter flowers of humanity, and a flower fête would be poor indeed, if not graced by our sister woman; but one striking feature of the evening company was the great preponderance of men, and especially young men, showing that they as well as their mothers, and sisters, and sweethearts, were recognising the powers of floral beauty as a refining, softening, and elevating influence.

And, lastly, such successful gatherings should impress on gardeners even a deeper sense of responsibility conjoined with true manly self-respect. As we witnessed the Show, we could not help reflecting that then there were three great educational establishments within a stone's throw of each other. First, there was the railway terminus, a good type of a system which has contributed most effectually for the

rooting out of prejudices and narrow-mindedness, by so greatly enlarging the field of our vision and our intercourse. Then there is the noble building, proof of private munificence and corporate liberality, appropriated to the instructive museum and the spacious library and reading-room open to all classes; and, lastly, there is the gorgeous St. George's Hall, devoted to the means of expanding heart and mind, opening up to many new sources of interest, and impressing all with proofs of the goodness of the Creator, in scattering with liberal hand the elements not only of the necessary and the useful, but also of the sweet and the beautiful. To whom are the inhabitants of Liverpool indebted for this last-named source of enjoyment? Without undervaluing other agencies, we say advisedly, chiefly are they indebted to the simple-mannered, clear-headed, warm-hearted, and hard-handed gardeners. A gentleman lately has raised some commotion by publicly stating that there were no great horticulturists now. It was, no doubt, a slip of the tongue, and some of us who make slips with tongue and pen, should be generous in such matters. St. George's Hall showed no proofs of retrogression. Great men lived before, but greater men and greater gardeners have lived since the times of Agamemnon. If there are now fewer towering trees among the surrounding brushwood, it is because the once brushwood has been cultivated to rival the trees in their godly proportions. The possessor and the manager of the gardens connected with princely mansions and baronial halls, may not stand alone in intellect and genius; but it is because equal genius and intelligence are possessed, united with untiring industry, among the managers of the gardens connected with the villas of the merchant and the tradesman. It would be well if such capabilities united with sterling honesty were more generally appreciated. Even now, however, every gardener wields a power for conferring pleasure and happiness, and power of all kinds is best associated with felt responsibility. Like all people who live much alone, we are apt insensibly to become prejudiced and narrow-minded. Surely those who are recognised as the means of imparting so much pleasure to others, may well strive earnestly to rub off all those jutting angularities that a kind of seclusion is so apt to engender, and thus endeavour to become as distinguished for breadth of view and expansion of ideas, as for that kindness of heart which has hitherto characterised the brotherhood. The more men thus secure their own self-respect, a very different thing from puffed-up self-esteem, the more will they command and receive the respect of others.—R. F.

### ROYAL HORTICULTURAL SOCIETY.

FLORAL COMMITTEE, *March 21st.*—The second meeting of this year was held at South Kensington on Tuesday last. The plants sent for examination were numerous and interesting. The collections of plants exhibited by several nurserymen and others were very excellent, and a great many certificates were awarded. Mr. Veitch sent several new and rare plants; the following were distinguished by first-class certificates:—*Urceolina aurea*, a greenhouse bulb, the plant unlike any we have seen before, producing large, thick, oval, green leaves, and a cluster of bright yellow drooping flowers, which are tipped with green, with a white margin; *Rhododendron Princess Helena*, sweet-scented, delicate, rose-coloured flowers, one of the hybrids between *jasminiflorum* and an unknown species; *Siphocampylus* species, a new climber, with bright purplish crimson flowers, promising to be very useful and ornamental—(we did not learn whether this was a stove or greenhouse plant; if the latter it will speedily find its way among numerous admirers);—a new distinct tree Fern, *Dicksonia Youngii*; and *Lomaria L'Herminieri*, a beautiful Fern; the young fronds, which spring from the centre of the plant, are of a pale red tint, which, surrounded by the green mature fronds, make it very conspicuous. Special certificates were awarded to plants from the same firm, comprising a beautiful *Cyrtopodium Lowii*; a very fine specimen of *Cephalotus follicularis*, growing from one crown, an extraordinary example of good cultivation; also a fine collection of plants containing a well-grown specimen of *Azalea Queen Victoria*, *Lycaste Skipperi*, *Acacia Drummondii microphyllum* (which we hope

to see again), *Anthurium Scherzerianum*, *Cymbidium eburneum*, and others. A label of commendation was given to a new *Peperomia*, with bright green foliage.

Mr. Bull sent a new Palm, a very beautiful specimen *Brahea dulcis*, which was awarded a first-class certificate; and *Lomatia elegantissima*, a pretty finely-cut-leaved greenhouse plant, which, in 1864, received a second-class certificate, was now awarded a first-class. Second-class certificates were given to *Elæagnus japonicus aureo-marginatus*, a useful hardy ornamental shrub for covering a wall; *Arisæma ringens purpuratum*, a curious form of the Arum family, differing from *Arisæma ringens* in its purple stem. Mr. Bull also sent *Elæagnus japonicus albo-variegatus*; *Elæagnus japonicus reflexus variegatus*; *Camellia Prince Camille*, a deep rose imbricated flower, of excellent form; *Camellia Comtesse de Gonda*, the flower not open; *Nephrodium molle cristatum*, and *Anthurium angustioranum*. A collection of plants, consisting of *Imantophyllums*, *Dracænas*, &c., received a special certificate.

Mr. Parker, Tooting, exhibited his seedling *Rhododendron*, Countess of Haddington, which received a first-class certificate in 1864. Messrs. Windebank & Kingsbury, sent a very choice collection of *Primula sinensis*, double and single-flowering, the four selected received a first-class certificate. These were—Glen Eyre, a fine double purplish rose; *Kermesina*, double carmine or rosy red, a novel colour; *Stewartii*, single white, striped with pink, fine large yellow eye; and Miss Eyre Crabb, single white, striped and mottled with rose. A special certificate was awarded for the whole beautiful collection, which was universally admired. Mr. Williams, Holloway, sent a new handsome *Dracæna limbata*, first-class certificate; and *Yucca Stokesii*, *Y. quadricolor*? *Dasylyrium glaucum latifolium*, and *Hechtia* species—a special certificate was awarded for the collection, three fine specimens of *Imantophyllum*, and a fine and beautiful collection of *Sarracénias*, which most justly deserved and received a special certificate.

Mr. Wilson Saunders exhibited a very interesting collection of plants, which were awarded a special certificate, containing *Pyrethrum Corona* de Regna, *Drymonia* sp., from Mr. Weir's collection, a seedling *Amaryllis*, the curious *Arisæma ringens*, which attracted much attention; *Imantophyllum*, *Gladiolus* sp., from Mr. Cooper's collection, a very minute form of this beautiful flower, white with brownish markings, not much larger than *Lobelia speciosa*; *Solanum vescum*; also a new *Pelargonium*, of dwarf habit, from the Cape. It had bright green lobed foliage, with a deep zone, and the plant grew close to the pot. It will, doubtless, afford a fresh groundwork for hybridising. Mr. Saunders kindly presented the Society with a fine plant. We trust that other amateurs will follow Mr. Wilson Saunders's good example, and send interesting specimens from their private collections, which will make these meetings of so much more importance and interest. Mr. Earley, gardener to F. Pryor, Esq., Digswell, sent a large tray of beautiful cut flowers, which were awarded a special certificate.

FRUIT COMMITTEE—George F. Wilson, Esq., F.R.S., in the chair.—At this meeting prizes were offered for the best three dishes of dessert and kitchen Apples respectively, and for the best collection of salads. In the former class, the only exhibitors were Mr. Earley, gardener to Felix Pryor, Esq., of Digswell; and Mr. George Curd, gardener to M. G. Thoytts, Esq., Sulhampstead, both of whom sent duplicate collections. Those of Mr. Earley consisted of *Sturmer Pippin*, *Cockle Pippin*, and *Wheeler's Russet*; and *Cockle Pippin*, *Fearn's Pippin*, and *King of the Pippins*. The flavour of all in both collections was inferior, with the exception of *Sturmer Pippin*, which was excellent. Mr. Curd's collection consisted of *Lamb Abbey Pearmain*, incorrectly named *Nonpareil*; *Vineyard* (wrong); and *Cluster Golden Pippin*; *Margil*, *Adams' Pearmain*; *Cockle Pippin* (wrong). In consequence of the numerous errors in nomenclature, both collections were disqualified, and a second prize was awarded to Mr. Earley.

In the kitchen Apples, Mr. Earley had *Lord Duncan*, *Dumelow's Seedling*, and *Gooseberry Apple*, to which a second prize was awarded; and Mr. Curd had *Alfriston*, *London Pippin*, and *Norfolk Beefing*, all of which were fine specimens and splendidly kept. To these a first prize was awarded. Mrs. Crabb, of Southampton, sent five dishes of *Blenheim Pippin*, and of *Uvedale's St. Germain Pears*.

Mr. George Tillyard, gardener to John Kelk, Esq., of Bentley Priory, exhibited several handsome bunches of Muscat of Alexandria Grapes splendidly set with fine plump berries, none of which showed any symptoms of shrivelling.

Mr. Brown, gardener to Mrs. Alston, of Elmdon Hall, Birmingham, exhibited large, handsome, and beautifully-coloured specimens of Easter Beurré Pears, the flavour of which had almost passed, but of which there was enough left to show that it had been of unusual excellence in that variety. The fruit had been grown against a wall.

A seedling Apple, of unusual excellence at this season of the year, was exhibited by Mr. House, of Peterborough, and which has been named "Lord Burghley." It is of medium size, roundish, and slightly flattened; is somewhat bluntly angular on the side, and ridged on the apex, this being caused by the prominent termination of the side angles. The skin, on the shaded side, is of a deep golden yellow, and on that next the sun of a deep clear shining crimson. The whole surface is dotted over with large russet specks, like the Golden Reinette. The eye is somewhat closed, and set in a pretty deep basin, which is uneven in consequence of the angles which terminate there. Stalk half an inch to three-quarters long, frequently a mere knob. Flesh yellowish, very tender, leaving but little mark in the mouth, very juicy, sweet, and with a fine pine flavour and rich aroma. This delicious Apple is now in perfection, and has the appearance as if it would keep for two months hence. Apart from its excellent quality, it is highly ornamental, and has a tenderness of flesh and a flavour similar and equal to Cox's Orange Pippin. It was awarded a first-class certificate.

Mr. Earley, of Digswell, sent a collection of salads; and Mr. B. Marcham, gardener to E. Oates, Esq., of Hanwell, sent two specimens of Rhubarb jam; one made in 1863, and the other in 1864. Both had kept remarkably well and were considered very good; the former suggesting the flavour of Guava jelly.

A collection of seedling Apples was presented by Dr. Hogg, which he had received from M. J. de Jonghe, of Brussels, but there were none among them that attracted particular notice by their flavour.

THE scientific meeting, March 21st, commenced at three o'clock, J. J. Blandy, Esq., in the chair. After the Rev. Joshua Dix, and G. F. Wilson, Esq., had, as chairmen of the Floral and Fruit Committees, read over and briefly commented on the awards made by those bodies, the Rev. M. J. Berkeley proceeded to point out the most interesting of the objects exhibited. Before doing so, however, he stated that a gold medal had been awarded to Mr. Joshua Clarke, for the discovery of a new British plant, *Erucastrum inodorum*, in a railway cutting near Saffron Walden.

At the last meeting a species of *Brassavola*, allied to *nodosa*, and sent home by Mr. Weir, was exhibited. On consulting the "Botanical Magazine," and "Botanical Register," he found that there were two forms of that *Brassavola*, but not sufficiently distinct to be considered species. Mr. Weir's was the same as that figured in the "Botanical Register." A new and curious Gourd had also been brought into notice by M. Naudin, it was the same as that exhibited by Messrs. Barr & Sugden, as Prince of Wales, but on account of its unpleasant odour, he did not think it would ever become useful for ornamental purposes. There were at the present meeting two beautiful *Dendrobiums* from Mr. Bateman—namely, *D. luteolum* and *densiflorum*, in addition to which from another exhibitor there were two fine *Cypripediums*—viz., *hirsutissimum* and *Lowii*. In connection with Orchids, he owed to Major Trevor Clarke, two leaves of some species of *Cattleya*, from Bahia, and which were all spotted. Nothing was more common than for cultivators of Orchids to complain of this, which was the result of a parasitic fungus from abroad, and which would be figured in the forthcoming Number of the Society's Journal. As another instance of a disease imported from abroad, an eminent nurseryman submitted to him (Mr. B.) some *Camellia* leaves attacked by a fungus belonging to the genus *Puccinia*, and on his (Mr. Berkeley's) inquiring if the plants had come from Italy, he was informed that two of them had, and from these

two the disease had spread over the whole collection. He would direct the attention of the meeting to a remarkable specimen of *Arisæma*, a genus closely allied to *Arum*, to the Australian *Cephalotus follicularis*, a very remarkable plant, and more particularly to those curious plants, the *Sarracénias*, of which there were some fine specimens exhibited. They were very difficult to cultivate, the tubes of the leaves going off, and the plants consequently failing to produce their flowers, in which they would notice the curious expansion of the stigma. It had been supposed that these plants were peculiar to the bogs of North Carolina, but they had also been found in Guiana. There were one or two plants at the meeting closely allied to *Aroidæ*, one *Anthurium Scherzerianum* was very beautiful. He would also call attention to the *Dracænas* and *Imantophyllum miniatum*, from Mr. Bull, the latter being a distinct variety in respect to the size of its truss. There was a very curious sort of *Gladiolus* from Mr. W. Wilson Saunders, and which had formed part of a large collection from the Cape of Good Hope. It was so unlike any *Gladiolus* known, that doubts at first had been entertained whether it was really so or not, but a botanical examination proved it to be so. A *Drymonia* was exhibited. This genus was closely allied to *Gesnera*, and a curious fact had been stated in the "Belgian Horticultural Review," that the pollen of *Gesnera coccinea* would retain its fertilising power for two or three years. This was a fact, which in the hands of cultivators might lead to useful results. In the genus *Salix* he might remark, the pollen actually retained its fertilising power longer than the seeds their vegetative power. Among the other plants pointed out to the meeting, were *Lomaria L'Herminieri*, *Nephrodium molle cristatum*, a graceful plant allied to *Pyrethrum*, and called *Corona de Regna*, the *Elæagnus* from Japan, *Peperomia*, *Urceolina aurea*, Mr. Veitch's *Lycastes*, raised by Mr. Dominy; the Chinese *Primulas* from Messrs. Windebank & Kingsbury, of Southampton, and in one of the flowers of which nearly all the parts were changed into new flowers; *Brahea dulcis*, a new Palm, and *Lomatia elegantissima*.

Mr. Bateman expressed his satisfaction at Mr. Berkeley's having taken in hand the subject of Orchid diseases, as Mr. Berkeley stood at the head of the cryptogamic police, and there was no doubt that justice would be done on the culprits. Mr. Bateman then called attention to the two *Dendrobiums* which he that day exhibited, as affording a lesson to Orchid growers not to be discouraged by the appearance of the first flowers of newly-introduced Orchids. When *D. luteolum*, which was introduced by Messrs. Low a year or two ago, first bloomed, there were only two weak flowers; those present could see what it was now, it had been in flower six weeks, and had it not been cut it was likely enough to have lasted six more. Almost all our best Orchids when they first flowered appeared hardly worth exhibiting.

The Chairman announced that it was intended to have held a discussion on fruit and floral awards, but so much time had been taken up by the lecture on the subjects before the meeting that the discussion must be deferred to that day fortnight.

Mr. William Paul then delivered a very interesting and excellent lecture on the cultivation of spring flowers, dividing his subject into two heads—hardy spring flowers blooming from February to May, and hothouse spring flowers, or those requiring the protection of glass to bloom at that season. Mr. Paul's lecture closed with some remarks on forcing, and a vote of thanks having been passed to him, the meeting concluded, the Chairman announcing that the next meeting would be held on the 4th of April.

#### MR. W. PAUL'S SHOW OF SPRING FLOWERS.

THIS is held in a glazed apartment adjoining that devoted to the weekly shows, and a very excellent display there is, consisting of splendid Hyacinths, mostly of the same kinds as those which obtained the first prize at the Regent's Park, besides *Camellias*, *Epacris*, *Rhododendrons*, flowering Peaches, *Eriostemons*, Tulips, *Narcissus minor*, a very good kind for edging, and cut Roses. These subjects are to be replaced from time to time with others, so as to maintain a gay appearance throughout the month, and those who

seek a lesson in spring gardening will do well to inspect the exhibition of one so competent to instruct in the art.

#### FIRST SPRING SHOW.

This was held on Saturday the 25th, and never since the Society first commenced such shows has there been one so varied, so interesting, and in every respect so well calculated to advance the true interests of horticulture as that which we have now to report. From the Regent's Park Show having so immediately preceded it, that at South Kensington was in some of its features necessarily a repetition, but a repetition under vastly more favourable circumstances; for even the most strenuous advocates of canvas in preference to permanent glazed structures must admit that the latter are infinitely more comfortable for spring exhibitions, especially in such a March as the present.

And now of the Show. Hyacinths, of course, were the principal object; and in the collections from Mr. W. Paul and Messrs. Cutbush among nurserymen, and Mr. Young of Highgate among amateurs, right worthily were they represented. For eighteen Mr. Paul was first with splendid spikes of Von Schiller, Macaulay, Solfaterre, Koh-i-Noor, Miss Nightingale, all various shades of red; that rich deep-coloured variety brought out last year by the exhibitor—King of the Blues; Garrick, Van Speyk, Charles Dickens, and Grand Lilas, paler shades of blue; Feruck Khan, and Prince Albert, both nearly approaching to black, the latter a very fine spike of its kind; and in blush and whites, Tubiflora, Gigantea, Seraphine, Grandeur à Merveille, and Alba Maxima. Messrs. Cutbush came second; their collection contained two very conspicuous white-eyed, blue-flowering kinds—viz., Lord Palmerston, which, though bearing a certain degree of similarity in its general character to some other kinds, has a rich azure tint entirely its own; and Argus, a better known flower of a deeper hue, and having the white eye even more conspicuous than the preceding. Robert Fortune, another new variety, fully justified the appreciation of it entertained last year, for the spike was fine, and no doubt when older bulbs are obtained will be finer still. Haydn, another of the mauve class, was also fine; and there was an excellent spike of Ida, yellow.

In the Amateur's Class for six kinds, two of each, Mr. Young, gardener to R. Barclay, Esq., Highgate, was first with Mimosa (violet blue), Macaulay, Von Schiller, Van Speyk, Grandeur à Merveille, and Madame Van der Hoop; the second prize was withheld; and Mr. Higgs, gardener to Mrs. Barchard, Putney Heath, was third.

The class for six kinds, was open both to nurserymen and amateurs, and here Messrs. Cutbush took the first prize with Von Schiller, Macaulay, Duke of Wellington, Seraphine, Marie, and Grand Lilas; Mr. Young second; and Mr. Paul third, the whole of the spikes exhibited being good.

Hyacinths grown in windows, in pots or glasses, exhibited no improvement on last year. We have seen many better under similar circumstances. Perhaps after seeing the magnificent spikes grown in pots by Messrs. Paul and Cutbush, people are afraid to come forward. As it was, Mr. Bartlett, Hammersmith, was first, his Queen Victoria, La Dame du Lac, Charles Dickens, and Grandeur à Merveille, being by far the best exhibited; Mr. S. Young, Highgate, was second; and Miss Fortune third, the last having the only exhibition of Hyacinths in glasses.

New Hyacinths from Messrs. Cutbush, who were first, consisted of Thorwaldsen, marbled pale blue, shown last spring; Cuvier, pale blue, with indigo stripe in the centre of each petal; La Française, a large-belled white variety; Hogarth and Gertrude, rosy pink. Mr. W. Paul's consisted of Princess Mary of Cambridge, pale porcelain blue, with fine spike and bells—a variety of decided merit; Beauty of Waltham, rosy pink, with white eye and compact in spike; Goliath, pink, fine bells; Prince Albert, crimson, with a scarlet tinge on the outside of the tube; and Leviathan, with large white bells, having a slight rosy tinge, and altogether an attractive variety. Doubtless another season when older bulbs shall have been obtained the above varieties will be seen to much greater advantage as regards their size of spike, but judging from them as exhibited Princess Mary of Cambridge, Beauty of Waltham, and Leviathan appeared the most desirable.

Large collections were exhibited both by Mr. Paul and Messrs. Cutbush, and less numerous ones by Mr. Macintosh, of Hammersmith, and Mr. Young. In Mr. Paul's, which was first, we remarked Garibaldi, a fine deep crimson; Queen of the Netherlands, one of the finest of the whites; L'Espoia, primrose yellow; and Duc de Malakoff in its two forms, the one buff, the other distinctly striped with bright rose, and so unlike that one could easily believe them to be distinct varieties. Messrs. Cutbush, who were second, had also a large and excellent collection, but to enumerate all that were fine, or even a few of each colour, would occupy more space than we could afford.

Early Tulips were also shown in great perfection, both in twelves and in collections of upwards of a hundred, by Messrs. Cutbush and Paul, the former being first and the latter second in each case. The best kinds exhibited were White Pottebakker; Roi Pepin, white, flaked with red; Keizerkroon, yellow and red; Archduc d'Autriche, fine crimson and yellow; Proserpine, violet rose; Rose Luisante, Cramoisie Royale, Yellow Prince, Standard Royal, and Vermilion Brilliant. Among double sorts New Yellow Tournesol, Tournesol, and Duke of York, red and white, were the finest. In the Amateurs' Class, Mr. Young, Highgate, was first; Mr. Bartlett, Hammersmith, second; and Mr. Ford, Highgate, third.

Crocuses were exhibited in splendid condition by Mr. W. Paul, who was first; and Messrs. Cutbush second. Mammoth, white, was by far the best of its colour; Prince Albert occupied a similar position as regards blues; Cloth of Silver was the finest striped kind; and Golden Yellow appeared to be the most useful yellow. Good collections also came from Mr. Bartlett and Mr. Young, who were first and second in the Amateurs' Class.

Roses in pots were shown both by Messrs. Paul & Son, and Mr. W. Paul. Among those of the former we remarked fine examples of Maurice Bernardin, Victor Verdier, Le Rhone, Alba Rosea (very pretty in colour), Baron Adolphe de Rothschild, Charles Lefebvre, and Lord Clyde; whilst among Mr. W. Paul's were John Hopper, Prince of Wales, Senateur Vaisse, with several fine blooms, and numerous buds of Anna Alexieff, &c. Several boxes containing excellent blooms of the above and numerous other varieties came from the same exhibitors.

Cut blooms of Camellias were exhibited by Mr. Trussler, gardener to J. Kay, Esq., Esq., Hoddesdon, Messrs. Lee, Hammersmith, and Mr. Paul. Among them were several very good examples of the old Double White, Fimbriata, Elegans, Donckelaari, Colvilli, Eclipse, carnation flaked; Jenny Lind, a beautiful blush white; Picturata, &c. First, second, and third prizes were awarded to the above exhibitors in the order in which they are named. Messrs. Lee and Mr. Bull likewise exhibited Camellias in bloom, and received second prizes.

Of miscellaneous collections of flowering plants the best came from Messrs. Lee and Bull. Among the subjects exhibited by the former were *Medinilla magnifica* with five spikes of flowers, *Boronia pinnata*, *Hedera fuchsoides* in good bloom, an *Oncidium*, *Azaleas*, and *Dendrobium nobile*; whilst Mr. Bull contributed *Medinilla*, *Camellias*, *Azaleas*, *Dracenas*, *Imantophyllum*, and several of the plants which had been exhibited at the Floral Committee meeting of the preceding Tuesday, also the curious *Marcgravia rotundifolia*.

Miscellaneous subjects consisted of a splendid collection of *Cyclamens* from Messrs. E. G. Henderson; *Lilies* of the Valley from Mr. Paul and Mr. Bartlett; *Narcissus* from Messrs. Cutbush; six plants of tree *Mignonette* trained on wire and in good bloom, from Mr. Higgs, gardener to Mrs. Barchard; *Rhododendron* Countess of Haddington from Mr. Parker; *Azaleas* and *Primulas* from Mr. Todman; the splendid new *Azalea Stella* (orange scarlet and violet) in fine bloom from Mr. Veitch; a neatly-filled plant case from Mr. Bull; Horse Chestnuts rooted in glasses from Miss Lane; bouquets and baskets of spring flowers from Mr. Lucking and Mr. Greeves; and ornamental flower-pots, baskets, &c., in Etruscan ware from Messrs. Hooper & Co.

From Mr. Hannan, gardener to J. Crawshaw, Esq., Cyfarthfa Castle, came two good Pines; from Mr. Shuter, gardener to the Earl of Wilton, Heaton Park, Manchester, bunches of Lady Downe's Grape ripe in October last; and

from Mr. Miller, Coombe Abbey, the same variety ripe in August last, and in both instances the Grapes were in excellent condition—another proof how valuable this variety is for late-keeping. Mr. Miller sent in addition a dish of Dwarf Kidney Beans.

The greatest curiosities, however, were the two plants of the common *Aucuba* in fruit from Mr. Laing which were noticed last week, and a fruit of *Ficus Cooperi* ripened in the Society's garden at Chiswick and very ornamental in appearance, being red mottled and speckled with yellowish white, but whether it is edible or not has not as yet been ascertained.

### CHEAP CONSERVATORY DECORATION IN WINTER.

THE subject of flowers for the winter decoration of the conservatory having been lately brought forward in your columns, and as it is one well worth following up, I will with your permission briefly state what I generally find the best for the purpose, and I hope to see many more come forward and do the same.

Presuming that the *Chrysanthemums* have lasted till the beginning of December, I generally grow a good quantity of *Primulas* in 32-sized pots, and with a little pushing they always come in about that time, and last a long while; also a good batch of early *Camellias*, *Deutzia gracilis*, which I consider to be first-rate, and a nice sprinkling of *Epacris*; so that with *Primulas* for pink or rose colour, *Camellias* for scarlet and white, *Deutzias* with their beautiful feathery blooms, and the various shades of *Epacris*, I generally manage to have flowers till after Christmas.

For January I always depend upon early-sown *Cinerarias*, close-potted, and kept near the glass, forced bulbs, of sorts, and *Crocuses* in particular, also *Mignonette*, forced *Azaleas*, *Epiphyllums*, of sorts; *Polygalas*, in small pots; *Primula nivalis*, *Correas*, of sorts, *Begonia fuchsoides*, in small pots, and hardened-off gradually; forced *Roses*, *Acacias*, and *Cytisuses*, early-flowering *Heaths*, *Aotus gracilis*, *Lobelia Paxtoniana*, first-rate, and small plants of the various bedding *Geraniums*, forced *Rhododendrons*, *Calceolarias*, *Salvia patens* and *fulgens*. These with a few stove plants sparingly introduced form the supply for flowers till the end of February, after which time there is no lack of material to choose from; and for foliage I have *Araucarias*, of sorts, *Camellias*, and *Oranges*, with the various *Retinosporas*.—BURNWOOD, P. D.

### THE ART OF CHOPPING.

CHOPPING is an art, and one that is not to be acquired in a day. Those who have handled the axe from earliest childhood, and become familiar with its management, have little idea of the awkwardness felt by those who make their first attempt at chopping, after having arrived at mature years. However, with a little perseverance, the art may soon be acquired by parties who have been accustomed to handle tools of a very different description. There is, however, a great difference in the facility and effectiveness with which people handle the axe. One man will chop much faster and more neatly than another. Nor is it merely a question of muscular strength. Skill has far more to do with it. A small man, possessing apparently but little strength, will often chop twice as much as a burly, powerful fellow, who "hasn't got the hang of it," as backwood-men would say. It is difficult to prescribe rules for handling the axe properly. An easy swing obtained by straightening the back at every stroke, and throwing the axe well up into the air; a straight aim; firm grasp of the handle hilt in one hand, and quick, free motion with the other; perfect elasticity in the arms; and the avoidance of all stiff, rigid movements;—these are the chief requirements. But, after all, there is a certain knack which only intuitive perception and intelligent practice can give. We are not sure but the true chopper, like the true poet, is "born, not made."

Much labour is avoided by making a careful examination of the ground and timber before beginning, and especially ascertaining the direction of the prevailing winds in spring

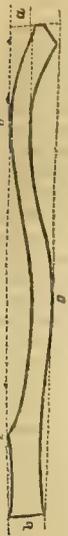

and summer. This will sometimes be indicated by a slight lean on the part of the trees, and more distinctly, perhaps, by the inclination of the tops. In commencing a piece of chopping, the largest and most unmanageable tree should be felled first, and if the prevailing wind be from north-west, the tree should, if possible, be made to fall towards the south-east. Then by carefully cutting the rest of the trees within reach of this first tree they will all fall with their tops on the first tree felled, the trunks forming various angles with that of the first tree chopped down. As each tree is felled, the branches should be all cut off so as to form a compact mass. Where the timber is thick these heaps will be nearly, if not quite, close enough to walk over through the entire extent of the fallow. When a tree is bent so as to fall the wrong way, it will often reach another row, or if the inclination be not too decisive its course may be directed by the use of a "spring pole," as it is called. This is a light, tough pole, about 25 feet long, with a strong sharp spike in the small end, protected from splitting by a ferule. When used, it is placed on the side of the tree opposite to that towards which the tree should fall, the spike thrust into the tree about 20 feet from the ground, and the bottom end jerked toward the stump of the tree. A small rope may be attached about half way up the pole and fastened round the stump below the place where it is being cut off. By doing this tightly, the pole will bend, and all its elasticity be made to contribute toward forcing the tree to fall in the desired direction. The use of the "spring-pole" requires much judgment and caution. A tree will usually fall on that side of the stump which is cut the lowest. If it be desired to throw a tree in a given direction, let it be first cut on that side 3 or 4 inches lower down than on the other side, and it will surely fall as intended, unless the wind is contrary, or the tree leans. These circumstances must always be taken into account at the outset to prevent mistakes and avoid accident. The direction in which the chips fly and the line they form as they lie on the ground will indicate where the tree will fall. Care must be taken and judgment exercised in felling trees to prevent mishaps. Accidents occur through ignorance or carelessness, and there are few cases in which injury is done by the falling of branches, or the tree going in the wrong direction, that the chopper is not to blame. Many act very recklessly, especially when the tree gets lodged in an adjacent tree. In such a case great caution should be used, no risks run, and no hasty measure attempted. Better take a little more time than hazard life or limb.

Before closing these remarks about chopping, it may be useful to say something about the axe, and the mode of "hanging" it, as it is called. The annexed figure represents an axe ready for use:—A is the poll, which is often made of steel; B is the edge; c the steel; d the outside corner; e the inside corner; f the eye through which the helve or handle passes, and into which it is wedged; g is the helve or handle. H is the hilt of the helve or handle. The dotted lines represent the angle of the axe and helve, and show how the axe should be hung. Axes are made of different sizes and weights, choppers are not agreed as to whether a light or heavy axe is the more effective. Perhaps it depends somewhat on the workman. A slow chopper can use to advantage a heavier axe than a man who is quick in his movements, while the latter will make up in the number of his blows for the lightness of the tool he works with. A good helve or handle is very necessary in order to be pleasant and effective for work. In many cases it so happens that the chopper must make his own helve. This is not an easy task. Many a good mechanic cannot make a helve fit to chop with. Our space will but admit of a suggestion or two in reference to this point. In the first place,

the helve must be flat or rather oval, as a round helve will turn in the hand, and is neither pleasant nor safe to work with. The shape will be better understood by the help of

the following diagram, which will also be a guide in making the helve:—About 2 feet 8 inches in length from *a* to *b* will suit most men. It is well, if it can be done, to take a good helve as a model, but if this cannot be done, a pattern can be made in a few minutes out of a thin piece of board, as shown by the dotted lines. At *a* it should be about 3 inches wide, and at *b* about 2½ inches wide. At *c* about 6 inches from the end near *a*, make a mark for the most prominent point. At *D* make another mark about two-thirds of the distance from *a* to *b*. At *E* make another mark 6 or 7 inches from *b*. The shape should be marked out with a pencil, as nearly like the figure as possible, and then it should be cut out very carefully and exactly. Tough hickory is the best wood for a helve. Rive out a piece and dress it four square, as thick at the large end as the hilt, and wide enough to mark the shape with a pencil by the pattern. Then with such tools as may be at command, reduce it to proper shape and dimensions. Drawing-knife, smoothing-plane, spoke-shave, rasp, and sand-paper, are most convenient, but sometimes all these are not within reach. In laying the pattern on the stick let the part at *c* *E* be towards the bark, and the part at *D* towards the heart of the tree. Then if the helve springs no mischief will be done, but rather good,

while if it springs sideways it will be worthless for chopping purposes. In hanging the axe, as it is termed—i.e., putting the handle in, it is necessary to have the edge range exactly with the centre of the hilt, and also to have the hilt, the centre of the eye, and the centre of the blade, at right angles.—(Canada Farmer.)

**OXALIS CORNICULATA RUBRA.**

I AM indebted to my friend, Mr. Thomson, of Archerfield Gardens, N.B., for a stock of this beautiful miniature Oxalis, and from what I have seen of the plant in question, I am bound to corroborate his statements in its favour; it will become a general favourite with the ladies, if not I shall be greatly deceived. For edging purposes in narrow borders or small beds, there is no plant of its colour so admirably adapted. It is compact in habit, rarely exceeding from 4 to 6 inches high, with foliage resembling the finest tinted Beet, and surpassing the Perilla in my estimation. In its younger growths it resembles the *Amaranthus melancholicus ruber*, but as it advances the foliage assuming a darker tint. It strikes freely at any season, as freely as a Verbena, and will bear the same winter treatment, or it may be raised from seed, but it is rather a difficult matter to secure seed, owing to the extreme irritability of the seed-vessels characteristic of this class of plants. If it is desirable to save seed place the plant on a large sheet of clean paper, and allow the seed-vessels to burst unaided, when the seed can be collected and sown at once. I have raised some hundreds of seedlings this winter, which will make good plants by May. I do not advocate this mode of propagation where there is a good stock on hand; but with a scarce plant we are all anxious enough to make the most of it. This will prove a most useful plant in the north of Ireland, rain not affecting it injuriously in the least, but rather the contrary, and after a good watering it looks all the more brilliant. To those who do not possess it, I say, Secure it as soon as possible.—JOHN EDLINGTON, Wrotham Park, Barnet.

**GLASS EXCESSIVELY BRITTLE.**

I CANNOT but think much of the sheet glass now used is imperfectly annealed, or otherwise badly manufactured. It is to be expected that a certain amount of breakage will occur during frost, particularly if the laps of the panes are too large, because a drop of water when frozen must occupy more space than when in a liquid form. But I have observed panes of glass crack gradually from edge to edge of a large square when the temperature varied considerably, even though no ice was formed. Many persons with whom

I have conversed on the subject seem at a loss to account for much of the breakage which occurs in their glass-houses, and I think it well to call attention to the subject. Perhaps some of your numerous readers who are competent to give an opinion, may be induced to give us information.

I know one large builder who has lately changed his market for glass, from an idea that what he has purchased breaks more than he expected. The glass in question is made at one of the largest manufactories in the country, and the first feeling of dissatisfaction was produced by its excessive hardness, rendering it difficult to cut, and spoiling so many of the men's diamonds. It appears to me a very important question, because if the reason of glass breaking is because it is not well annealed after being manufactured, it is clear that extra strength will give no guarantee against loss by breakage.—J. R. PEARSON, *Chilwell*.

**MESSRS. CUTBUSH & SON'S HYACINTH SHOW.**

THIS commenced on Tuesday last, and will continue open till the 1st of next month, affording a rare treat to the lovers of flowers. With Messrs. Cutbush the Hyacinth is an object of special attention, and the reputation which they have acquired in connection with its culture, is sufficient guarantee that the display which they annually and freely offer to the public, is of no ordinary degree of merit; and this season the show is fully equal, if not superior, to those of former years.

In the red class of Hyacinths, there were some noble spikes of Von Schiller, Macaulay, and Florence Nightingale, whilst Queen of Hyacinths, and Solfaterre, were very brilliant in colour; La Prophète, Princess Clothilde, and Mrs. Beecher Stowe, were also fine. In double varieties of the same colour, Duke of Wellington, very pale rose, was the most attractive, while for a deeper shade there were Susannah Maria, and Koh-i-Noor. In blues, Lord Palmerston was, of course, one of the most beautiful, whilst Thorwaldsen is another variety of first-class merit, having very large marbled blue bells. Grand Lilas, Couronne de Celle, Bleu Aimable, Marie, and Van Speyk and Garrick, double, may be added as sorts of well-established merit. Argus, too, is pleasing as a white-eyed kind. In mauve, with the exception of Robert Fortune, which made its appearance last year, Haydn is the best. In whites, Queen of the Netherlands, and Madame Van der Hoop, were very fine, also Sir Bulwer Lytton, a novel double variety, with large bells of great substance, and in colour white, with a tinge of pale rose. Alba Maxima, Mont Blanc, Grandeur à Merveille, and Gigantea, white; Ida, and Duc de Malakoff, yellow; General Havelock, and many other varieties, were also worthily represented. The only novelty not before seen was Hogarth, a soft pink, which promises to be a desirable kind. As usual the back of the house was filled with Fairy Roses, Cytisus, Azaleas, Heaths, Pelargoniums, Camellias, and other flowering plants, whilst the early Tulips added not a little to the general effect.

**WORK FOR THE WEEK.**

**KITCHEN GARDEN.**

*Artichokes*, the spring dressing to be given to them by digging and levelling the ground between the plants. All suckers to be reduced to three on each stock, and if a new plantation is made, the suckers to be planted three in a patch, 3 feet from patch to patch, and 4½ feet from row to row. *Asparagus*, the general spring dressing, if not yet done, should no longer be delayed, as the roots will now begin to grow. *Broccoli*, a little early Purple and early White may be sown for autumn use; but Cape and Grange's almost supersede the use of any other sorts for that season. *Brussels Sprouts*, make a sowing if not already done. *Canliflowers*, earth-up the early-planted as soon as it can be done, so as to prevent the wind blowing them about and loosening them. *Cucumbers*, take advantage of a fine day to draw the earth round the hills after it has lain a day or two by the side of the frame to become warm. Do not press it down round the plant. As soon as the heat begins to fail, fork-up and add to the lining, or if the heat is entirely gone, renew the

lining. After a continuance of dull weather, the plants are apt to flag for the first few clear days, when this is observed they may be slightly shaded. *Herbs*, should now be propagated, seeds being sown of the annual sorts and such as do not supply cuttings or admit of being divided. *Potatoes*, put in the main crops where the ground is in good working order. Plant in trenches in preference to dibbling the sets in. *Salading*, keep up a succession by sowing once a-week. Young *Radishes* may be drawn from the frames where they are too thick. *Spinach*, sow a few rows for succession, limiting the supply to the demand. *Tomatoes*, pot them as they require it, so as to have well-established plants by the time the weather will permit of their being turned out, for if very small at that time, they seldom ripen their fruit well before frost sets in.

#### FRUIT GARDEN.

To obtain good *early Grapes* from Vines on the open walls, all that is necessary is established Vines, a common hotbed frame or two having three or four lights, a load or two of dung and leaves, and a few slates or plain tiles. If the Vines are pruned, which they should have been before this time, make a bed of leaves and dung of the size of the frame about 4 or 5 feet high, and 2 feet from the wall. Use the short dung at the top, and put on the frame immediately. After the heat is up, fork it up a little once or twice, and if it becomes dry water it slightly. After the violent heat has somewhat subsided, cut notches in the backs of the frames and bring down the branches of the Vines. A trellis should then be fixed inside at about 6 inches from the glass, to which the Vines must be tied. When this is completed close the frame, and let it so remain unless the bed is very hot, when a little air must be given until the buds begin to push, after which they must have air according to the state of the weather. When the buds are about breaking, the dung should be covered with slates or tiles to keep down excess of heat and steam. When it is necessary to thin the *Grapes*, the lights may be drawn off, as also for stopping and thinning.

#### FLOWER GARDEN.

Those who force Neapolitan *Violets* should for the next three weeks or a month propagate a stock, either by means of cuttings or runners. Look well to recently transplanted trees and shrubs, especially such as may have been shaken or partially uprooted by the recent high winds. When the weather shall have become warmer, a sprinkling overhead with the engine on the evenings of dry days will be of service to large evergreens. Seeds of perennials and biennials to be sown, such as *Wallflowers*, *Sweet Williams*, *Polyanthuses*, *Canterbury Bells*, *Pinks*, *Carnations*, and *Picotees* for flowering next year; *Heartsease*, *Antirrhinums*, and *Sweet Scabious* sown now will flower in the autumn. When the flower-stems of *Auriculas* are rising an abundance of air should be supplied by drawing off the lights every fine day, and replacing them at night, covering during frosts with mats or straw. It is necessary to be cautious not to expose the plants too hastily to the sun in a morning after frost, but to allow every appearance of it to vanish before they are uncovered. Sow choice *Ranunculus* seed in shallow pans or boxes, cover the seeds as lightly as possible, and place the pans in a cool frame.

#### GREENHOUSE AND CONSERVATORY.

The application of fresh soil and humidity will, in many cases, be required to supply the necessities of growing plants. Greenhouse plants for the most part require a considerable amount of pot-room, as many of them, particularly the soft-wooded sorts, are free growers; but the tender or more weakly-growing kinds must be shifted with caution to avoid overpotting. When *repotting* plants it is generally recommended to use the soil in a rough state—that is, not sifted, but made fine by rubbing it through the hands, picking out the small stones, &c., and also to use plenty of drainage. If plants were to be treated on the one-shift system—that is, removing them at once from a small to a very large pot, such drainage would be necessary to keep the mass of soil in a dry and healthy state; for it would otherwise become sodden after waterings before the roots had made much progress; but according to the general practice of shifting to the next larger size of pot so much drainage with a porous soil is unnecessary at this season—at the approach of warm weather it is a disadvantage, because with such free drain-

age and a rough porous soil the watering-pot must be in frequent use, and almost at the same time that the water is applied to the top of the pot it is seen or heard to pour out at the bottom. When plants are shifted in the autumn a porous soil is then more necessary to keep the roots in a dry healthy state during the many dull, damp, and dreary weeks of winter, but now so much porosity is not necessary, and, therefore, it should be considered and acted upon during the spring and summer potting of plants. If specimen plants are in good health, and the pots well filled with roots, they will grow and flourish all the better if they now receive a liberal shift, and be kept rather close and moist for a short time until they make fresh roots, when they may be more freely exposed to sun and air. It is necessary to be very careful not to give too much water to recently-potted plants as it is frequently the cause of their death. *Fuchsias* should now be making free growth in the warmest part of the greenhouse; to be syringed overhead every fine afternoon, stopped if long-jointed to form compact bushy plants, but if intended to be planted along the sides of walks or as single specimens on grass, they should be grown with one main stem, from which the branches will spring all round and form fine pyramidal specimens for pleasure-ground scenery. Attention to be paid to cleanliness in every particular by removing dead and decaying leaves, keeping a sharp look-out to destroy green fly and mildew.

#### PITS AND FRAMES.

It will be necessary to keep up a kindly heat in the cutting-frames, to top all cuttings that have taken root and are beginning to grow. The autumn-struck cuttings that were potted off last month to be removed to a cold frame or pit, and protected from frost.—W. KEANE.

### DOINGS OF THE LAST WEEK.

#### KITCHEN GARDEN.

HERE little was done out of doors, owing to the frost, which ranged from 6° to 16° below freezing on the three first days of the week. A good opportunity was presented for trenching for *Sea-kale* and *Asparagus*. Notwithstanding the coldness of the weather, *Asparagus*, *Sea-kale*, &c., in the open ground, are moving nicely, and the long tubular roots are becoming covered with fresh spongioles. If an opportunity offers, we may be inclined to plant a piece of *Asparagus* before the shoots appear above ground, though in general we prefer planting when the tops are from 1 to 2 inches in length. However, this does not much matter if the roots are carefully taken up, kept moist, and shaded, so as not to hurt the young spongioles by exposure. On this account plantations generally do better when the roots are merely taken from one part of the garden to another. When the plants are sent any distance it will be found better to have them taken up just as the roots begin to move, and before the tops show at all above ground. Removed a lot of *Sea-kale* from Mushroom-house into a sheltered shed, where it can be hardened off gradually before planting again in the open air. If this is not done it is advisable to place some protection over the heads when planted out at once. It is always wise to avoid any sudden check if possible. The same plants of *Sea-kale* may thus be grown and forced even when taken up a long time; but it is as well to give them the ensuing and the second summer's growth before taking them up. The crown ends will, however, do very well the next winter, but pieces of the root, all of which will grow, like two summers' growth. This taking up, and placing the roots thickly in any dark warm place, is the cleanest and most economical mode for having this delicate vegetable early in winter. Such forced plants, as stated above, should be well hardened off before planting them out again; and they should not be cropped too hard—not more than two cuttings on the average. We have sometimes taken three and four cuttings; but in that case, do as you will, the old roots are of but little use, as all the strength is taken out of them. *Rhubarb* stools, forced and hardened off, may also be divided and planted in the same way. They will just grow slower at first than old plants in the ground, taken up and divided. Now is a good time for that operation, as the buds can now be well seen, and old stools may be divided into pieces having two or three buds

each. Forced roots, that have been taken up for the Mushroom-house, when divided and planted in deep rich soil, generally beat seedlings, however carefully they are treated. Asparagus, Sea-kale, and Rhubarb should now be sown. Where there is plenty of these for winter, a good security is obtained for a well-served table. Gave the general routine attention to other vegetables. It is to be hoped that the snow and hail will bring warmer weather, as these severe frosts and easterly and northerly winds are not only keeping things back in the garden, which may be a great advantage ultimately, but are keeping the pastures from moving, a very serious matter to all possessing flocks and herds, especially if scarce of corn and fodder.

#### FRUIT GARDEN.

Fortunately the cold winds kept the buds of fruit trees so backward that we hope they will suffer but little from the severe frosts. On Monday morning fixed a number of extra Laurel twigs among the shoots of Apricots and Peaches, and shut the orchard-houses at night, as we are anxious to keep the trees from opening their bloom until as late as possible, without shading them. Even when the thermometer fell to 18° below freezing point it scarcely affected these orchard-houses; but then they had been shut up early in the afternoon, enclosing a good amount of sunshine. But for that we should have found it necessary to have protected the pot plants, as Peaches, Strawberries, &c. It was, therefore, so far fortunate that there were bright days along with cold nights. The very brightness of Monday, the 20th, following after the leaden cold sky of Sunday, and coming after such a severe frost, with an excessively cold temperature in the shade, rendered firing and air-giving a matter of some importance. The safest plan, in all such cases, is to let the heating medium cool as long as the sun shines, and to give only a minimum of air, and that, in ordinary structures, at the highest point of the roof. A strong artificial heat in such days is not merely waste, but the dry parched air that must necessarily be admitted robs tender plants of their vital juices without mercy, and sickness and inroads of insects are the general consequence. Even damping and shading, under such circumstances, are better than introducing great draughts of cold air among tender plants, or those made tender by forcing. It is of importance so to keep things under glass hardy, that they may stand the rays of the sun without flinching; but plants that will do so in general will often be distressed when the sun shines very brightly for a day after several days of great dullness. A little shading and a moist atmosphere, then, will just enable the plants to accommodate themselves to the changed circumstances. The bright sun, though so desirable in general, must, in such circumstances, be regulated, and fresh air, though also desirable, does not necessitate the sending a northern icy blast among tender plants.

Disbudded Peaches, arranged Vines, potted Melons, moved Strawberries to the best places at command, and set out and regulated the second orchard-house, appropriating the front part of the lean-to house to three rows of trees in pots again, as that longer time may be obtained for forming a definite decision as to planting, &c. Last season they did very well, and would have done better, could we have watered enough. That, in fact, is one of the chief objections we have to growing fruit trees in pots. We hope, however, that this season we shall not be annoyed by such scarcity of water as during the last season. *Strawberries* are now coming better; but we have had more *blind* pots than usual, though we are thankful to say that ours are not nearly so bad as those of numbers of our correspondents. We refer a greater per-centage of failures than usual, to our shortness of water last summer and autumn, and being obliged as a last resource to use liquids in anything but a fit condition. One of our readers told us the other day, that of his nice-looking Strawberry-pots four-fifths had failed. That is certainly a very great drawback. Last season ought to have given us first-rate fruitful plants, but it is just possible that some little neglect in watering under such sun and heat might have starved the fruit-bud even when the plant continued to look well. We found our own plants much smaller than usual, owing to our drought, split themselves up into several buds or crowns, which we never like, as we always prefer one strong, well-ripened, single bud.

Some correspondents have also desired us to say, that

presuming a Strawberry-house is more desirable than shelves put up anywhere and everywhere, what is the kind of house we would recommend? and to this we reply, that without saying a word against the plans and houses for Strawberry growing lately given by our coadjutor, Mr. Abbey, were we to have the pleasure of building a Strawberry-house, we would closely follow the section lately given of the Strawberry-house at Enville. The practical man knows that such a house need never be a single hour unoccupied in any day of the year.

#### ORNAMENTAL DEPARTMENT.

Out of doors the work has chiefly been turning over flower-beds, rolling the lawn, and pruning shrubs when the weather would permit. The frost has rendered a little protection necessary to Tulips, Hyacinths, and even Pinks and Carnations newly planted. Fortunately the ground was dry, or some things would have suffered much from the cold. Annual seeds but for that would have suffered if sown early. The period of germination just when the little stem and roots protrude is the most trying, and hence it is that self-sown seeds generally suffer less from changes of weather than those artificially sown. Natural instinct, as it were, tells them the best time for bursting their shell. We have known beds of Mignonette sown in March, that never produced a plant, whilst seeds self-sown in autumn from plants from which the seeds were gathered, after being exposed to all the changes of winter, produced a thicket of plants in May, when left entirely to themselves. Even in the case of hardy annuals, those sown in autumn often do better than those sown very early in spring. In general, April is soon enough, when a regular crop of plants is desired.

*Hyacinths Forced.*—There are very general complaints of these not coming up to the mark this season. Various reasons have been assigned—the late frosts of last spring, or rather early summer—the taking the bulbs out of the ground earlier than usual as respects the season of the year—and, owing to the demand for bulbs being greater than the growers could supply, sending bulbs into the market with fewer years' growth given to them than usual. Our opinion is that there may be something in all these causes united. What with spring flower gardening, and the winter and spring supply of flowering bulbs, the regular growers in the Low Countries find it hardly possible to get land enough for their purpose. One of our eminent nurserymen told us lately that within two or three years his trade in bulbs had increased fivefold, and that if he pushed it at all he could sell many more could he fully satisfy himself as to the quality. Even this season some of the seemingly finest, hardest, plumpest, well-ripened bulbs turned out with him rather inferior. With all this, however, we think it right to state that amateurs and small purchasers do expect more from their bulbs than is quite reasonable. If you purchase a dozen plants of one variety from a nurseryman, there will often be variations among them as to growth and habit for which it would be difficult to give a reason. This is especially likely to be the case with bulbs. A very little difference in the age, in the growth and the ripening of the previous season, will tell on the strength and beauty of the flower-stems when forced the following spring. Often the proprietors of nice villa gardens are apt to become dissatisfied, and perhaps blame the gardener, when, do what he will, of their dozen or score of Hyacinths each one does not come up to their expectations. They go to a spring show, and they cannot conceive how their dozen of bulbs should not be pretty well as good as any dozen exhibited at Regent's Park and Kensington by such good growers as Messrs. Paul, Cutbush, &c. They forget that these great growers make bulb culture a speciality, whilst bulbs form a small item in the things demanding their gardener's attention. Besides, we are quite sure that they would oftener be satisfied rather than dissatisfied with the number of really good flowers they obtain from a small collection, if they knew that the best growers, with all their acquaintance with the best kinds, and giving them the very best treatment, fail to bring every bulb equally good. A gentleman lately grumbled that, after giving an order for eighteen of the best Hyacinths, intending to compete in a class of twelves, he found it was no use trying for anything but sixes, and, to make sure of being first, he must be content with threes. Well, if he took honours in sixes, and in the face of good

competition, we think he had reason for congratulation. He had an idea that the great growers selected their twenty best from some thirty or forty bulbs. We think it much more likely that they had some hundreds to pick and choose among. The best cultivators would be the first to confess this. But these matters, though they may apply to strict florists, the flower-stems which they would reject would be none the less beautiful to those who see beauty, though not arrayed in defined forms and shapes. To all such, a vast variety of showy bloom may be obtained from the cheaper collections of Hyacinths. What we wish clearly to enunciate is just this—that all who wish to have a certain number of first-rate flowers for any occasion must grow more than they absolutely want for that purpose, so as to have numbers to choose from.

We continued potting, striking cuttings, &c., during the week, and felt thankful that we had not yet turned anything out into earth-pits for the flower garden, though most of our houses are now unpassable for gentlemen, and far less for ladies. We shall leave these just to say one word on

**Heating Small Houses.**—We can add nothing to what was said in answer to two correspondents a fortnight ago, as to stoves, gas, &c. We believe that for every small house close to a residence that now exists, there would be twenty, if it were not for the heating question. We believe that all the modes referred to will be effectual if the little trouble is given, and that gas where easily obtainable would give the least trouble, whether used for stove or for stove and their boiler and their pipes. We have had several letters on the subject, asking our opinion on this and that plan, but we would rather not give more of opinion and belief, but prefer instead to listen to the practical results of those who have tried the different modes, as we are not in a position to test them ourselves. What makes us the more anxious is, that the reports received are very contradictory, especially as to the expense of the modes of heating. We have taken the opportunity to consult a friend, who from his position, and courtesy, and popularity, has been greatly consulted on such matters, by residents in the suburbs of large towns, and he tells us that the reports he receives are very conflicting, one gentleman stating that the heating of his little house with gas has made no appreciable difference in his gas bill for the year; a second stating that the expense for his small house averages 1s. per week; whilst a third says, that the expense in his case is ruinous, averaging 10s. per week. Of course, this must have been a larger house. These conflicting results led our friend to advise a course with these little ornamental houses, which we mention as it may suit some, and which has been followed by many of those who asked his counsel, and that is simply to treat such houses as a cold or unheated house. To do this and also keep up the interest of the proprietors in their own plants for the summer, he advises growing the hardier plants in summer, as Fuchsias, Scarlet Geraniums, Salvias, &c., and as winter approaches, pruning these partly at least, and placing them under the stage, with the means of covering the stage over in severe weather, and then bringing in winter-flowering Jasmines, Laurustinus, Arbutus, and other shrubs, and early bulbs to enliven the house for the winter.—E. F.

TRADE CATALOGUES RECEIVED.

Charles Turner, Royal Nurseries, Slough, and Salt Hill.—*General Spring Catalogue for 1865.*  
Joseph Wood, Florist, Bowness, Windermere.—*Priced Catalogue of British Ferns.*

COVENT GARDEN MARKET.—MARCH 25.

Out-door vegetables continue scarce. Forced vegetables and continental supplies have also declined.

TO CORRESPONDENTS.

\* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

PUNNETS.—"A. B." wishes to be informed where he can purchase some punnets.

FLOWER-GARDEN PLAN (*Calcaria*).—Your copy of the plan at Putteridge bury of a group of beds on the east side of the mansion shows the centre bed larger than that in proportion to the other beds, and even that is too large for the other clumps, but is neutralised in the planting. You would require a good broad band of *Lobelia* round the *Calceolaria Aurea floribunda* to prevent the yellow drowning the other beds. We think the group would be improved and be better balanced if you put three colours in the bed—say *Victory* or *Crimson King* in the centre, and then yellow and blue. In the arrangement of the other eight beds you sometimes balance or pair the beds, and at other times there is the plan of having every bed distinct—now one or other should be followed. We prefer balancing. Instead, therefore, of having 2, 3, 4, 5, filled with *Madame Vaucher*, *Stella*, *Christine*, and *Trentham Rose Geraniums* respectively, we would make 2 and 3 *Stella*, edged with *Christine*, and 4, 5, *Trentham Rose*, edged with *Madame Vaucher*; then we would have 6, 7, *Scarlet Verbenas*, edged with variegated *Arabis*, as you propose, but in 8 and 9, instead of having one cross bed of *Purple King*, and another of *Snowflake*, we would centre both with *Snowflake* and border with *Purple King*. In your long bent bed we would take the border all round of *Cerastium* on both sides, then your *Lobelia*, and centre with *Golden Fleece*. The bed would look very pretty after edging with *Cerastium* to dot with *Golden Fleece*, or *Cloth of Gold*, or *Golden Chain*—the latter two better than *Golden Fleece*—and then fill all the other spaces with *Lobelia*.

INDIAN CORN (*A. Z.*).—You were answered at page 133. It will not succeed.

VINE LEAVES WARTED (*H. H.*).—The little elevations with brown tips on the under side of the vine leaves usually arise from the roots supplying sap to the leaves faster than these can elaborate it. Free ventilation and less moisture in the air will check this appearance, but it is not at all incompatible with a superior crop of fruit, being indicative of vigorous growth.

GROWING THIN MUSHROOMS (*S. G.*).—To get thin Mushrooms you must keep them drier and use lighter and less rich materials to grow them in. Most people like them thick and juicy, but Mr. Fish has several times stated that by using a covering of cow dung beneath the soil they become too thick for some people's taste. For some purposes such thick Mushrooms might be sliced across. Most people like them the better for being thick and juicy, but a gardener should study the tastes of his employer.

A THREE-TERRACE CIRCULAR BED (*A. N.*).—We would plant the top with *Stella Geranium*, the second with yellow *Calceolaria*, and the ground tier with *scarlet Geraniums Tom Thumb*, or *Little David*, or *Boule de Feu*, and edge with a hanging border over the stakes of the white-leaved *Geranium*. A very good arrangement would also be white-leaved *Geraniums* for the top, with the flowers taken off, second tier *scarlet Geranium*, bottom tier *Aurea floribunda Calceolaria*, with a hanging edging of *Verbena pulchella*.

FORCED STRAWBERRIES UNFRUITFUL (*W. A. O.*).—If you wish the Strawberry plants that have failed, to fruit in the same pots next year, we recommend you to protect the pots when you set them out of the house. Then place them against a north wall to have comparative rest, and about the middle of June thin out the smallest buds, shake away a good portion of the soil, and repot firmly again in fresh soil; shade for a week or so in bright sunshine, and then expose carefully to the sun, and treat as if younger plants. You will then most likely obtain a heavy crop, but in general the individual fruits are not so fine as from younger plants.

PUTTERIDGEBURY (*A. Reader*).—We are sorry that as yet no definite information can be given as to the matter to which you refer. If no notice appears perhaps it would be as well to write to Mr. Fish during the summer, when, no doubt, he would act with his usual courtesy.

**NEGLECTED FRUIT TREES (J. C. L.).**—It is not too late for pruning in your locality if you do so at once. The hedges, if not evergreen, may be cut. Hollies and other evergreen hedges, shorten in with the knife late in next month.

**CLIMBING AND TRAILING ANNUALS FOR WINDOW (R., Dartford).**—*Thunbergia alata* and *T. alata* are showy plants, requiring to be raised in a gentle hotbed; *Tropaeolum Lobbianum* Caroline Schmidt, with deep scarlet flowers, would also answer; *Tropaeolum Brilliant* is also good; *Gypsophila muralis*, pink; *Sanvitalia procumbens*, yellow and brown; and *Saponaria calabrica*, pink, are trailing plants of compact growth. For such a situation as inside your south window we would not recommend the above, but have *Maurandya Barclayana* and its white variety, one or both of the *Thunbergias*, for the climbers; and *Convolvulus mauritanicus*, *Nierembergia gracilis*, and *Lobelia speciosa*, for suspending.

**VINEY REPLANTING—BORDER-MAKING (Yorkshire).**—The Grapes being cut in June, and the Vines not being wanted for replanting, we would at once make a new border and plant the Vines. Provide yourself now with the Vines you intend planting. We recommend for an outside border—one Buckland Sweetwater, one Foster's White Seedling, one Black Hamburg, one Pope's or Victoria Hamburg, and one Black Prince or White Frontignan, just as you wish for a black or white Grape. You could not well select a worse Grape for an outside border than Canon Hall, and if you require the Muscat flavour choose White Frontignan, which is by far the best of the Frontignans, and the only Grape with a Muscat flavour worth planting in an outside border. Keep the Vines you have as cool as possible, and disbud them to the height required, leaving two shoots at the height, where the Vines when planted would reach to the rafter. Provide turf cut 3 inches thick from a pasture where the soil is neither strong nor light, a lightish yellow loam being best. In an open spot pile this layer above layer, grass side downwards, in a stack 4 feet wide, and as much high, and have ready a quantity of old brick rubbish to mix with it at the rate of one cartload of brick rubbish to six of turf, adding to each cartload two bushels of boiled half-inch bones, and a like quantity of charcoal. When the Grapes are cut dig out the border the full width if there is time, but 6 feet from the front will do. If you have the option make the greater part of the border above ground, and if the situation is low and wet there is the greater necessity for doing this, and concrete the bottom. Mortar riddlings from 3 to 6 inches thick, beaten hard, put them on in thin layers and beating every layer. On this place from 6 or 9 inches to a foot of stones, half bricks, &c., for drainage, and the bottom of the border should slope to the front, where there should be a drain with an outlet at one end. Place the roughest drainage materials at bottom, and the finer at top, cover the drainage with a layer of sods, grass side downwards, and on the sods lay 2 feet of the compost; throw roughly mixed, chopping the turf a little but not very fine, and beating down with a fork, so as to consolidate the compost a little. Having laid 20 inches of the compost on the drainage, and keeping some chopped finer close by, turn the Vines out of the pots, having first introduced the cane through the aperture into the house, and disentangle the roots without breaking or injuring them, and spread them out on the surface. Cover an inch deep with the fine soil, and water with aired water. Plant the whole, and then, commencing with the first Vine, place over it 3 inches more of the general compost. Shade from bright sun and strong light, sprinkling the Vines with water frequently during the day, and keeping the air of the house moist by sprinkling every available surface. If dry weather ensue the Vines should be watered at the root, mulching the border with short litter to prevent evaporation. After they recover the planting make choice of the best shoot, cutting the other away, and remove the shading gradually. Keep the house rather close, giving air early and closing early, and maintaining a moist atmosphere.

**MANAGING ORANGE TREES IN TUBS (A Subscriber).**—The trees being properly retubbed they would require some time to make fresh roots before they would show any benefit from the fresh compost in the shape of growth, though they would have grown had they been placed in a suitable temperature. Oranges do not usually flower until April or May under ordinary treatment, that being bare protection from frost. If you could afford the fresh-tubbed trees a nice moist atmosphere, with a night temperature of 50°, with a rise of 5° on dull days, 10° on those which are cloudy, with clear intervals, and 15° to 20° on clear days, with corresponding ventilation, they would be gently stimulated into growth, increasing the temperature in a fortnight to 55°. The trees may be syringed overhead morning and evening with water of the same temperature as the house, and the paths, flues, and hot-water apparatus, being sprinkled twice or thrice daily, this will raise a moist growing heat, and the trees will soon show their flowers and make new growth, the appearance of the flowers being dependant on the ripening of the wood the preceding season. Keep the soil moderately moist, neither very wet nor very dry, but moist enough for the roots to run in, giving copious waterings until the roots have taken firm hold of the soil. Water copiously whilst growing, and keep the soil well supplied with moisture whilst the fruit is swelling, lessening the supply in winter, wet being then worse than dryness, though both are injurious. A temperature of from 40° to 45° is sufficient in winter.

**SEEDLING CINERARIAS (Country Curate).**—They are pretty, but none that are good florists' flowers. Considering the thousands which are raised annually, it is rather curious that so very few are excellent or novel.

**VINE LEAVES CRUMPLED (T. B.).**—The appearances exhibited by the leaf enclosed are those arising from a check given to the Vines after growth has commenced, and may be caused by the dry cold air admitted in ventilating the house, and a deficiency of heat and moisture in the house at the time. The leaves on the young plants will be all right when the season is more advanced. The temperature after the leaves appear should be 60° at night, and 75° by day, when air may be given, 70° by day from fire heat being sufficient. Those fruiting in pots would have been less liable to a check or to injury from the changes of the atmosphere had they been plunged—if in bottom heat so much the better. The insect is *Cureulio picipes*, or Pitch-black weevil. Search for it at night, spreading a white cloth beneath the plants on which it feeds, and shake the plant over the sheet.

**FUCHSIAS FOR EXHIBITION (R., Dartford).**—The best Fuchsias of last year's for exhibition and decorative purposes are Charming, Don Giovanni, Printair, Sunshine, Cloth of Gold, when well grown is very beautiful, Minnie Banks, amongst light ones in excellent, and the largest white-coralled Fuchsia is perhaps Emperor of the Fuchsias.

**FLOWER-GARDEN PLAN (Gertrude).**—It is not advisable to send a list of plants on one page and a plan on another page, which we can only see by turning the leaf. We think your proposed planting will do very well. The white Chrysanthemum will do mixed with the Scarlet Geraniums if the white is good, and kept the same height as the Geraniums. In order to work in your materials we would either mix or ring the three circles at each end, the two opposite each other with pink, or scarlet and yellow, and the other one by itself, with purple and white. We can hardly depart from the resolution not to plant beds or give the best planting, for that would require the whole time of several of our best coadjutors at this season; but if you choose to repeat your plan, however coarsely, and tell us your proposed planting, we will criticise it and tell how, if possible, it may be improved. For this purpose you should state the size of your beds. If you edge all the central beds with *Cerastium* your using one or two colours in the beds will depend on the size of the plants you bring next the *Cerastium*—for instance, if you used a tall *Calceolaria* a row of purple *Verbena* would bring it down to the *Cerastium*. We cannot be sure of the plant of which you send leaves because you do not give its height, nor whether it is hardy. If hardy, and the flower stem about 1 foot or 6 inches in height, then we suspect it is a variety of *Ajuga alpina*, or reptans, as one or two varieties have purplish leaves and blue flowers. We are not sure, however, whether the leaves are purple, or have become so from the packing. Some of the tall *Lobelias* have leaves very similar, but then these have generally scarlet and not blue flowers, and they are not generally hardy. Let it be clearly understood that it is next to impossible to name many plants from a leaf alone.

**EARLY TULIPS SHORT-STALKED (Idem).**—The pots, or a paper funnel inverted over the flowers, would have done good to the Tulips as well as the Hyacinths. We fear manure water will now be too late, but there is no harm in trying. We hope the greenhouse treatment will improve them. See a note on Hyacinths in "Doings of the Last Week."

**SOAPSDUDS (E. A. P.).**—There is very little fertilising matter in soapsuds alone. It would be a trifle better than water for all the Cabbage tribe. Mixed with house sewage it would form a good liquid manure for the same and all other kitchen garden crops.

**CUTTING IN VARIEGATED HOLLY (H. N. E.).**—You may cut the Holly into the required shape in May, but the more small shoots that are left the fuller the leaves will come. It does not matter about leaving any leaves, we having reduced several a yard all round, and left nothing but bare stumps, so as to have the appearance of deciduous trees in winter, and by autumn they were as full of leaves as possible. If the weather be dry after cutting we water twice a-week during its continuance to make sure of growth, and not unnecessarily lose time. We find they do better if not cut until the eyes in the axils of the leaves have begun to swell. We have some perfect cones that were the ugliest shrubs imaginable before they were cut in.

**NAMES OF PLANTS (Ceterach).**—1, 2, *Polystichum angulare*; 3, 6, 7, *Asplenium adiantum-nigrum*; 4, *Lastrea dilatata*; 5, *Lastrea Filix-mas*; 8, Too young to identify. (*Drina*).—1, *Polypodium vulgare cambricum*; 2, *Asplenium appendiculatum*; 3, *Polystichum angulare proliferum*; 4, *Lastrea Filix-mas*; 5, *Asplenium flaccidum* var.; 6, *Polystichum angulare*, young; 7, *Polystichum aculeatum lobatum*. They will all grow in a house without heat. (*B. C.*).—1, *Polystichum acrostichoides*; 2, *Platyoloma rotundifolium*; 3, *Ceterach officinarum*; 4, *Polystichum vestitum* var.; 5, *Selaginella Martensii*; 6, *Polystichum angulare*. (*J. H. Marsh*).—1, Appears to be *Davallia dissecta*; 2, *Gymnogramma Martensii*; 3, *Lastrea decurrens*. (*S. T. Wills*).—Your Fern is *Asplenium adiantum-nigrum*; the leaf is of an *Acacia*. (*A. W. C.*).—*Solanum capsicastrum*, a South Brazilian plant, suitable for pot culture, and very ornamental when covered with its scarlet berries. (*M. D.*).—*Frimula denticulata*, var. *erosa*.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### THE COLD WEATHER.

We have been surprised to find how little our chickens have been affected by the cold weather. Perhaps it is, that being so few in number, they are tended with more than usual care. The old birds have suffered much, and although well fed, they have proved but scanty layers. We hear from all quarters, the great want is broody hens. We know places where there should be from two to three hundred chickens, and where there are but twenty or thirty. Pheasants and Partridges are affected by this weather, and if it lasted till their laying season, they would be a week or ten days late in laying. They are not so affected by vicissitudes as ordinary poultry, because they are subject to one season. Nevertheless, those we have in confinement are not more forward than they appeared to be in January. Their one season will come, but some of us want two seasons out of our hens, and all want to rear as many early (?) chickens as they can. As soon as there is a change of the horrible weather everything will start into life. All the hens will lay, many will want to sit. Days are getting longer, nights are getting shorter, the sun is gaining power, the necessity no longer exists for restricting the hens to small numbers of chickens, and March and April must do the work that January and February have left undone. Some of the good ladies of the poultry-yard must allow their progeny to be put out to wet-nurse.

Put eggs under three hens at the same time, a full number, thirteen. Should they all come out, each hen must keep her lot. If they only partially hatch, put all the chickens at once to two hens, and let the third be one of three more put on fresh eggs, taking care that the second time she is allowed to hover those she has hatched. But in order to reduce hatching almost to a certainty, the eggs should be examined at the end of a week or ten days. All the bad should be thrown away, the good ones put under hens that were nested at the same time. It may be done in this way. Choose a sunny morning, and the middle of the day. Hold the egg against any small opening in the door or other part of the building, where there is a strong concentrated ray of light. Look at it through both hands placed telescope fashion. If the light comes clearly through it, and the whole of the egg is of one uniform warm bright colour like the sun, it will never produce a chicken; but if like the moon it has dark shades and spots it is good. These may be seen at the end of four days. Then when the eggs are within two days of hatching get a pailfull of warm water, and choosing the time when the hen is feeding, put the eggs into it. They all swim, and after a minute or two, one will give a sort of jerk, because he feels the warmth, another and another will do the same, till they are all dancing the most extraordinary quadrille ever seen. They elbow, kick, and bang each other, and seem to enjoy it so heartily, that one is almost tempted to put the ear down to the water, in the expectation of hearing laughter inside the shell of a merry one, or a deep "gluck, gluck, gluck," like the Dominie in "Jacob Faithful," from some staid and steady chick that is obliged to laugh, but thinks it *infra dig*. The eggs seem to enjoy it immensely, and our conviction founded on considerable experience, is, that the chickens hatch all the better. The softening of the shell renders their exit easier, and they come into the world stronger. The two or three sulky eggs that take the blows and return none may be discarded. It may be truly said they have no life in them. These little precautions make hatching almost a certainty, and by discarding the bad eggs at the end of a week, and just before hatching, time is saved. Perhaps after the water test, one-third of the eggs submitted to it are rejected. All the good and lively ones are put under two hens, and the third is put on fresh eggs. Spite of all these precautions some will fail, but where they are adopted there is little disappointment.

**THE ACCRINGTON POULTRY SHOW.**—We have been requested to make public a great contemplated improvement in the management of the Accrington Poultry Show, to be

held on the 6th and 7th of April next. All the poultry, and Pigeons also, will be exhibited at the same elevation, and not tier above tier as heretofore, while every specimen will be exhibited under cover, the omission of which precaution at former meetings left all the birds to take their chance of weather, and, consequently, limited the entries accordingly. As the prize schedule is much increased, we hope to find the coming Show greatly improved both as to quality and quantity.

### POULTRY AND EGG-PRESERVING COMPANY.

WHATEVER differences of opinion may exist as to whether poultry can be kept profitably in England from a strictly commercial point of view or not, it is certain that this subject will never be satisfactorily decided by any amount of mere theoretical assertions *pro* or *con*; nor will the problem ever be solved in a national point of view by the success of one or more private persons, whose balance-sheet would be discredited by many sceptics, as we have had ample evidence, in improved farming, the results of which were published year after year by Mr. Mechi and other pioneers. Moreover, to render poultry-breeding profitable in England it must be evident to most persons that the system cannot be carried on as it is now; also that the trial must be made on a somewhat extensive scale to allow of growing or purchasing food at a cheap rate, and of a subdivision of labour, and last, but not least, for establishing a profitable outlet for the produce. Now there are many undertakings which cannot well be tested on a small scale in order to prove what the result would be on a large one, and we believe that poultry-breeding in England is one of them.

It is too much to expect that any private gentleman would run the risk of an outlay of some thousands of pounds to ascertain the value of a new plan of breeding poultry in order to benefit the nation; but as the subject is really one of national importance it is highly desirable that it should command a fair trial. This can be best accomplished by a public company whose accounts would be audited by independent accountants, and the statistics of which would be reliable, and, consequently, valuable to the country at large.

In a former Number it was stated that plans were afoot which would, in all probability, result in calling public attention to the subject and in giving the question a fair trial on a large scale. Since then the preliminary prospectus and the plans have been issued.

Mr. Geyelin has evidently the utmost confidence in the success of the undertaking, as he has taken on himself the trouble and expense of bringing this subject fairly before the public, and he gives the free use of his inventions to the Company, not for a cash consideration, but for shares the value of which must entirely depend on the profitable result of his system of poultry-keeping.

A Company of this description requires only half a dozen gentlemen earnest in their efforts to carry out the proposed system. On our part we shall watch the result of this long vexed question, Can poultry be bred profitably in England? with great interest, for if successful, poultry will be sold, as it ought to be, by weight, like other articles of food.

### EXTENSIVE POULTRY-KEEPING.

YOUR correspondent "NEMO" deserves the thanks of the readers of THE JOURNAL OF HORTICULTURE for his sensible and well-timed remarks on the proposed Poultry Company. If others as well qualified to pass an opinion on the matter would give their advice as candidly and unreservedly, valuable service would be rendered to your subscribers—valuable in either case as encouragement or warning. What says your excellent contributor "WILTSHIRE RECTOE?" The expression of his opinion would command respect. Not every one who gives the public the benefit of his experience assumes to himself the functions of a "public Mentor." That exalted title would apply rather to him who should instruct us in the art of producing such enormous profits by poultry-keeping. We and our grandmothers, it seems, have to be taught at last "how to suck eggs." Let us be teachable.

My own opinion, gathered from personal observation, is

that a large number of fowls cannot be kept in one spot without serious detriment to their health and profitable employment; that the profits arising from them do not increase in proportion to the number kept; and that no appliance, however ingenious and seemingly well adapted to the purpose, can possibly compensate for the loss of the natural parent. The instincts of the chicken during the most critical period of its existence are feeble, it requires not only the sheltering warmth of the mother's wings, but the mother's watchful care, her affectionate warning, advice, and instruction. No artificial contrivance can provide these. We may hatch eggs, but we cannot successfully rear chickens by machinery.

These remarks are dictated by no spirit of hostility to the proposer of the Poultry Company. I do not know Mr. Geyelin. His very important suggestions and clever arrangements will meet with the confidence of the public in proportion to their standing the test of friendly criticism. This will prove the most profitable advertisement of his scheme if deserving the serious attention of the public.—T. W.

### SCHEDULES OF POULTRY SHOWS.

MR. J. WRIGHT is in error—as to my having written the postscript without reflection. It is very easy for us exhibitors to say such and such are the “duties” of poultry-show committees—a difficult matter to make them see that these are duties. He says he received a catalogue without any application being made by him, and he says he ought to have received an amended copy. I think he was expecting too much. The alteration concerned Brahma breeders only, and I fancy was made on account of remonstrances from breeders of that variety. It is much too hard to expect that Secretaries are cognizant of the varieties which each amateur keeps; and on second reflection I continue of the same opinion as when I penned the said postscript. I think it would have been wiser, and I dare say more profitable, if Mr. J. Wright had acted as I suggested, and he would have done good to the Brahma cause. I am always willing to meet secretaries half way, and to help them if I can, for “to err is mortal.”

In reply to Mr. Irvine, Secretary to the Halifax and Calder Vale Agricultural Association, I plead guilty. I recollect that their schedules have been for “cock and one hen;” but I was treating the subject as regarded first-class shows. Bradford certainly was this, as it offered handsome prizes and silver cups—to the best of my recollection double the amounts offered by the Halifax and Calder Vale, and in the latter case the silver cups were more sparingly held out. Still I plead guilty to forgetting the fact, and I am very glad to add it as strengthening my position, and I trust both Bradford and Halifax and Calder Vale will in this respect find many imitators.—Y. B. A. Z.

### THE POULTRY CLUB.

In the first and second letters I wrote to you, I had no other than the best of wishes for the fair and honest judgment of all poultry be the judges or judge whom they or he may be, and I honestly and frankly avow the same to be my present feelings, and I do hope that you will believe such to be the case. I cannot refrain from expressing my regret, if my former letters have incurred the odium of any well-wisher of fair and honest judgment at our poultry shows. Neither must I forget to remind your readers that I have no ill-will or malice against Mr. Douglas or any other breeder or exhibitor of poultry, so that in touching upon certain letters which have lately appeared in your Journal, your readers and yourself will give me credit for doing my best to place our judges and their judgment on a more honourable and straightforward principle than I have reasons to believe they have been, more particularly since the Poultry Club took its stand in such a form as it has done. In your Journal of March 7th, I find an excellent letter from some one who, like myself, up to this date has written under an assumed name, I mean the one who styles himself “A LOOKER-ON;” and I must endorse his words when he says the Club has fallen into no small error by leaving the ap-

pointment of judges in the hands of dealers whose interest is to win prizes, not merely for the sake of the prize itself, but as a means of raising the value of the birds they have for sale. Which member of the Poultry Club will take up this subject and prove clearly to “timid exhibitors,” that it is not, to say the least, without its suspicions?

In your No. 203, February 14th, Mr. Douglas gives his advice on the wholesale system, to “A TIMID EXHIBITOR,” “Go boldly into exhibiting poultry, or if you keep in that timid state of mind you never will be successful,” and further wishes to stamp upon the hearts of exhibitors, that he has neither bred, sold, nor exhibited poultry for two years. Then, again, in No. 205, February 28th, he says, “The pen ‘A TIMID EXHIBITOR’ alludes to, as bought and sold at Manchester, was claimed when above one hundred were in the Show. It was claimed in my name, not by me, neither was it sold by me.” The first sentence is not true, if his words on the day in question are not worthless. How I pity the judge who will lend his name and confess it, and say afterwards, “Neither was it sold by me.” Perhaps he will alter somewhat in his tone after reading the straightforward and honest letter of Sir St. George Gore, in your edition of Tuesday last, and the public, I think, cannot entertain a great desire to see such a man of principle judging their produce. I leave it to you whether it is necessary to publish my name in place of “A TIMID EXHIBITOR.” If you desire to do so you have my full consent, particularly as several of your subscribers seem desirous to see who and what I am.—J. D. NEWSOME, *Batley*.

### THE OPENING SEASON.

How truly delicious to the snowed-up bee-keeper was the perusal of “A DEVONSHIRE BEE-KEEPER’S” “genial day” among his bees.

What a contrast Devon presented to Renfrewshire! Here wreath upon wreath of snow, with the keen frost and the thick pendant icicles—spring flowers, Crocuses, and Snowdrops, where were they? Just peeping through the ground, buried several feet beneath the snow; the bees close prisoners for many weeks. How could it be otherwise while bitterly

“Boreas wi his blasts did blaw.”

There spring flowers in full bloom, bees busy pollen-gathering, and even youthful yellow-jackets dancing with fiery radiance,

“While saft the westlan breezes blaw.”

With what a “longing for spring” did that paper inspire us we need not stay to depict, “Our chaplain” having already discoursed so eloquently from that text as only to require our emphatic Amen.

On Tuesday, February 22nd, the sun burst forth with something like spring brightness over the white and glistening landscape. Saw from the windows the snow barricades on the points of the landing-boards sensibly diminish, particularly those that had suffered most from the active tread of that sly little marauder Master Tom Tit, and finally to entice out the bees. Thinking it high time to substitute some more enduring sun shade for the hive-fronts, sallied forth; but there’s a lot of black-faced highlanders standing on their hind legs, tearing away most voraciously at some favourite ivy. They must get “a Scotch convoy” to the highway to seek their own home. We pity as we expel them, for they, poor things, are evidently starving. As we return, there, too, is a contrast. Their southern sisters, our own Leicesters, lying around their rack chewing the cud of sweet content, nothing disturbed by the “cawing rooks,” not cawing now, but mysteriously silent (although the first Sunday of March, their first field-building day, is so close at hand), as they pace along their broad backs, anxiously raising and carefully examining the silken staple. Not admiring it, surely? Only quietly hunting after small game, as they are also starving. Why do those skylarks raise their tufted crowns so delightedly as they dart from among that troop of poultry in the shed? They have just appropriated a few crumbs or potatoes dropped by those matronly Dorkings. They, too, are starving. But to the bees.

Knee deep waded along the garden walks, or, we should rather say, as nearly as we could guess where walks should

be. Recollecting pollen-gathering from the Devon Laurustinus, stopped and disinterred some upper branches of a shrub, and found the bloom not opened. Regretted as we strode along to see here and there on the top of the snow an Italian, now a Britisher, fallen to rise no more. In front of the hives the purity of the snow sullied with quite a shower of excreta, but, fortunately, fewer bees dropped than we had feared. No pollen-gathering—could it be expected? Made all snug and left them.

By Thursday following the snow had silently and quietly passed away, except where the drift had been deepest, as up against the garden wall and around the hives. Stood long and patiently in the wet slush watching the late arrivals, when lo! at longlast in goes an active little Ligurian. Wished to, but durst not, with so much snow still about the hives, raise the frames to ascertain what store was left; but consoled ourselves with the thought that, if short, we could administer a good supply of food directly into the combs, this time without our Devon friend coming down upon us.

Saturday, February 26th, snow entirely gone, mild for the season. Summoned our assistant and set to work. First out slides square straw hive, plenty of food, fair population, that lithe little yellow queen already at work, good sprinkling of eggs, and even some grubs about ready for sealing. Having been somewhat suspicious of the season and of some unhatched cells, around which the fresh brood and eggs were now deposited, excise all brood bed for another experiment, to ascertain if spring be more successful than autumn for the extirpation by excision of the bee plague. Cleaned board, and shut up in the hope that we, too, had had "a last glimpse of foul brood."

Next a black hive; not an egg, but very strong in population and store. Although breeding had not commenced, were struck at the forethought displayed by the workers in busily employing themselves during their confinement in cutting down the massive thicknesses of the emptied upper portions of the combs that had contained honey to the requisite narrow width for brood. As we scrubbed up our capital mahogany boards, artistically cut from old table-tops, we inwardly thanked your genial correspondent, "UPWARDS AND ONWARDS" for the hint. It may interest our old opponent of the "milk-pan and straw hackle" controversy to know that the shadow of the hated hackle has never been cast across his mahogany—we have long ago abolished them. And adopted the pan, eh? Oh, no, as great anti-panists as ever. Something better than either—handsome wooden octagon covers for Stewarton hives as figured in No. 9, only they lift off in a piece, and square ones in the same style for square hives; both of a sufficient altitude to take in the fullest set of storified hives.

The next, another black hive. As many eggs as in Ligurian, but no grubs, thus giving, say, eight or ten days' priority in favour of Italians.

In like manner the eight stocks composing the home apiary looked this. Gratified to find all well stored and peopled, particularly the last. An octagon storified Ligurian, from its determination to resist all interference, and its inmates having on one occasion last summer gained a complete victory over my assistant, has since been rated by him as quite a *noli-me-tangere*. As we approached it, his ready pipe was out at once—this was forbidden at the season—and the cover cautiously raised and slipped off as gently as possible. The inmates made a rush to the entrance in an instant; and before the hive could be raised and placed on the spare board a cluster hung on poor Friday's veil front, and a crowd on either hand, while numbers spread themselves all over his clothing and stung away with that hearty goodwill with which the Italian alone can. The hands were speedily transferred to his trowsers' pockets, and the body doubled up, as down the walk he tore at a great rate, leaving his master to clean the board and make all snug as best he could. On the hive being replaced, the bees were built up thick upon the landing-board, and up the hive front, more like June than February. We only wished "J. E. B." had been there to have seen and felt the weight of a real storified hive still 60½ lbs. gross with board.

In the afternoon set off and made a similar examination of the outlying apiary at a farm a mile or two distant. Accompanied by the old farmer, their custodian, went down

into the garden. A glance at the entrance of three of the hives, and then the following colloquy, which we must report for the edification of your Oxfordshire correspondent. "Halloa, Hugh, mice in all the hives! Why didn't you keep a sharp look-out?" "I thoct as muckle; but you see, sir, as they werna my ain I did na jist like to meddle wi them." Confound Scotch caution for once. Off first hackle, and out falls from its apex and rolls on the walk a pretty little ball composed of cut straw, beautifully arranged; how "UPWARDS AND ONWARDS" would have admired the snug little domicile! In each case the mice were gone, and these three Stewartons were all still well stored and peopled, although the deep cuttings into the rich end combs showed how luxuriously our little enemies had fasted during the severe weather. Never suffered from mice before, first indications of them in the home apiary at once putting us on the alert, what had tempted the aggression in this instance being the extreme lowness at which the permanent massive thick stone hive-boards were set bringing the hackles close to the ground. It may be worth noting that the combs generally were much better kept in the hives under the protection of the wooden covers compared with those under hackles. Although both were ventilated alike, still the farmer's hackles did not contain the same body of straw I used to employ.

A third small apiary was too distant to reach that afternoon; but there was no fear of mice there, as the custodian invariably places a bit of lead over the entrance, with only little cuts to allow the bees to be got out singly. We never approved of such contrivances. Nothing like a thorough circulation of pure air underneath hives during the dormant season. Was never more impressed than this winter with the great advantage of giving an ample supply of food when required in October, so as to permit the bees to enjoy a complete dormancy. No hive of mine receives a particle of food till the ventilating ekes are withdrawn in the beginning of April. Thankful to find all so flourishing, and not one foul cell in all my black colonies; those excised from the Ligurian one alone excepted, casting a dark shadow over the prospects for the season.

March 1st.—Young bees on the wing from octagon Ligurian above alluded to. Again the yellow-jackets are in the ascendant.

March 10th.—Cloud of young bees out of a strong black stock, confirmatory of a ten-days earlier start in favour of the Italians.—A RENFREWSHIRE BEE-KEEPER.

EGYPTIAN BEES.—In Lower Egypt where the blooming of flowers is considerably later than in the upper districts, the practice of transporting bee-hives is much followed. The hives are collected from different villages along the banks, each being marked and numbered by the proprietors, to prevent future mistakes. They are then arranged in pyramidal piles, upon the boats prepared to receive them, which, floating gradually down the river, and stopping at certain stages of their passage, remain there a longer or shorter time, according to the produce afforded by the surrounding country. In this manner the bee-boats sail for three months. The bees having culled the honey of the orange flowers in the Said, and of the Arabian jasmine and other flowers in the more northern parts, are brought back to the places from which they have been carried. This procures for the Egyptians delicious honey, and abundance of beeswax. The proprietors in return pay the boatmen a recompense proportioned to the number of hives which have been thus carried about from one extremity of Egypt to the other. The celebrated traveller, Niebuhr, saw upon the Nile, between Cairo and Damietta, a convoy of 4000 hives in their transit from Upper Egypt to the coast of the Delta.

#### OUR LETTER BOX.

INCREASING ROOM IN A COMMON STRAW HIVE (H.).—Get an eke made of straw of the same diameter as the hive, and of such depth as you may deem fitting. Raise the hive on it as soon as made, and keep it from slipping by means of a few stout hair-pins, stopping the old entrance and filling up all crevices with good mortar.

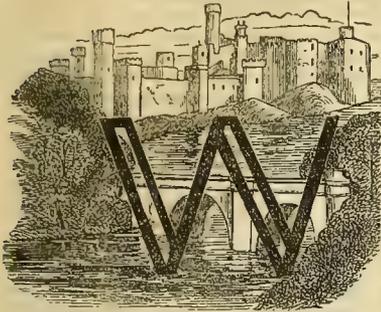

DOVES NOT HATCHING (C. E. M.).—As you mention your Doves sometimes sitting on four eggs, there can be no doubt but that they are two hens, consequently the eggs cannot be fertile. Buy two cocks, or exchange one for a cock.—B. P. BRENT.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 56.8°, and its night temperature 35.6°. The greatest heat was 79° on the 7th, 1859; and the lowest cold, 20°, on the 10th, 1860. The greatest fall of rain was 0.73 inch.

THE BREAK IN OUR CIRCLE.

WHEN I sent you last evening my mite for poor Mrs. Chitty and her babes, I did not think of saying a word about the sad event; but when I opened my Journal this morning and read the further words of Mr. Wills, and when I looked

through the second subscription list, in which I saw recorded the poor man's shilling (what a large part of his week's wages!) and the collection from the servants' hall, and thought, too, what my Bible says of "a widow and desolate," I felt a power over me which I could not resist (and why should I?), and so I too sit down to lay my wreath on the gardener's coffin. He was a good fellow, and he has departed this life—I do not say died, that word sounds cold, and harsh, and hopeless, while "departed" seems to speak of an entering into a better life, and to whisper of a re-union hereafter. We need not think of the departed, gathered, as we trust, into the safe home of Him our Saxon forefathers loved to call "The Good One." I think rather of the young widow and her and his little ones. But first let me remark that in writing in a periodical year after year one gets to feel that the other writers are somehow or other one's personal friends. We may never have seen them, as I never saw Mr. Chitty, but names seen each week become more than names when attached to outpourings of men's minds; we generally connect some idea of an author with his work. I have my own ideas of the outer man—the look, the eye, the expression of face of each writer. Well—one of the band is gone. A break has been made, by death, in our circle—one "has dropped and disappeared." Only thirty-three! and only a three-days illness! and five little ones left, and scarce one of the five beyond the age of babyhood. I close my eyes and think I see that gardener's cottage as it was a month ago. The mid-day meal is ready on the table, the wife's eye is on her clock, and her ear is listening for "father's" well-known footstep; little round eyes peep through the flower-pots in the window-ledge, and little feet rush to the door as a corner is turned and "father" is seen coming home. Down the path the children run, one tiny supported and pulled along by a bigger sister; that tiny will not walk back. No, she is caught up, and carried, and kissed, and petted. Then the meal and the little household events—important events in that little world (all in all to them)—are talked over. What shall be the subject of the next paper for the Journal? Wonderful feats, too, of baby are recounted, and bright say-

ings of another little one recorded. Oh! ye selfish, rich, single men, ye only think of a poor man's poverty, and not of that wealth of love which makes his home a paradise. Just a living and nothing to spare, with a good wife and little ones, are riches beyond aught ye can or shall ever know. I thought of that home as it was until recently, and then I thought of sadder things; of the sudden illness, and the first great thought of fear stealing on the wife's heart, and bidding hope leave it—until— But why say more? my own eyes are dim from the sad picture I have drawn. In that gardener's cottage

"Silence o'er the music fell,  
And darkness o'er the glory."

And now for the future; after Nature's great burst of grief has subsided, comes, for there must come, to the widow the thought of her future maintenance. A double burden will now be upon the weaker shoulders, children must be brought up without a father to labour for them, to advise them, to guide them. May God bless them, and teach their mother, that she may rightly teach them. Most properly a subscription has been started, and I hope to learn that the money raised will be carefully expended, or funded for a good purpose.

At present lies upon us the duty of giving. Kind, well-off people I ask you to help. If you have never known so great a grief, you might have known it but for His mercy. Show then your thankfulness by helping her whom God has smitten. Some of you have known similar griefs, you will give because you have passed through a like sorrow, and you remember your desolateness then. Some will say as they read, "I pity the poor woman." Then show me what your pity is worth by giving to her. And ye wives who press to your bosoms a child that yet catches at a father's finger, you will give, your husbands will let you, you will give money, and tears, too, I well know. And there are others whose lot has been cast in pleasant places, whose sorrows have been little, whose blessings great—ladies who live a calm and useful single life, but who would have had wives' and mothers' hearts had God willed it so, you have been spared many sorrows, and many cares, I ask you to give, and I know you will, to a "widow and desolate."

And now a word of advice to gardeners, you'll take it well from me I am sure. Let this death make you provident. There is the post-office savings bank, or the life assurance company, or, at any rate, some well-managed benefit society near you. Which will suit you best—one must.

A last word on a higher subject. Half in jest, and half in earnest, I have called myself, and have been called "The Chaplain" of the staff and writers of this Journal. Not the least in jest, but altogether in earnest, I will speak to you as a chaplain should. I say, then, when you see how soon one in health and youth is taken, and he is but one of many, for

"The knell hath tolled—the grave hath yawned  
For many a bright and blooming one;  
Radiant in life when morning dawned,  
But cold in death when day was done!"

Then, I would say, **BE READY.** There is One ever near to you, through Whom alone you can be ready, for He paid your debt—One who will meet you, especially at your bedside, night and morning. He is waiting for you. Meet Him, then, on your knees, and when death comes He will lead you to a garden (for in heaven there *must* be flowers) more beautiful than any on earth, more beautiful than even was Paradise.

So may poor Chitty's death draw out our active sympathy and cause us to do good to the bereaved, "the widow and fatherless in their affliction," and may it also be a means of good to ourselves.—**WILTSHIRE RECTOE.**

## GARDEN IMPLEMENTS.

(Concluded from page 224.)

### IMPLEMENTS FOR CARRYING AND APPLYING WATER, &c.

**THE WATERBARROW.**—A most useful implement where much watering is to be done and the water has to be carried any distance. It may simply be described as a tub on wheels, but a great deal depends on the form and construction. The best that I know is a tub holding about fifty gallons, swung on a frame, and to this frame are fitted two wooden wheels about  $3\frac{1}{2}$  feet high. The height of the wheels causes the whole to run easily. Wooden wheels make less noise than iron. The tub being swung prevents to a great extent the water slopping over. The water may be drawn from the tub by means of a syphon, or a tap fitted in the tub itself, from which, also, a hose may conduct the water to the plants to be watered, without the use of a watering-pot. There are waterbarrows made entirely of metal, and though inferior to those properly constructed of wood, their cheapness and durability are considerations which make up in a great measure for the loss of other qualities. It is also possible to construct one that will answer all the purposes of the best.

**GARDEN ENGINES.**—There are several patents for so-called superior kinds of garden engines, but, so far as I am able to judge, I have used none I like so well as Read's and Warner's, and these I have generally known to work well and satisfactorily. Beyond this it is scarcely necessary to say anything, but that the tubs should be often cleaned out, and none but clean water used; if dirt and grit get in the leather is apt to be permanently injured. The proper spreader should be used with every kind of engine; it will be found better in effect and more pleasant to use than any other. There ought to be sufficient force in the jet to throw the water over the highest fruit trees, the object being to wash dust, dirt, and insects from trees, plants, &c., and at the same time to afford an imitation of a shower of rain, so as to refresh and invigorate plants after hot days. The watering-pot can be more effectually used in applying water to the roots of plants, but the engine is best for cleaning and refreshing the leaves and shoots.

In connection with the garden engine there are other implements that claim a little notice. The Hydropult, for instance, is supposed to throw water as far as the garden engine, at all events it is very useful, particularly for indoors and small gardens. I would recommend it particularly in town gardens, where it should be used morning and evening in dry weather for washing the dust from the leaves of shrubs and trees. During the spring and summer the health of the trees and appearance of the garden will be vastly improved by such daily ablutions, and no one would begrudge the price after having seen the effects for a season.

There is something better still than a garden engine and syringe—that is a cistern, of sufficient dimensions to contain a large quantity of water, fixed on the roof of the house: from this a pipe is carried to such places as the water is to be applied, and stopcocks are there fitted, to each of which a flexible hose can be screwed, this hose being furnished with spout and spreader. If the cistern is mounted on a three-storey dwelling there will be force enough for all purposes. This will be found the best of all methods of applying water, and though rather expensive in the first instance, the money thus employed would be well spent. Where possible rain water should be conducted into the cistern, but failing that, river water will be the next best, and will answer very well.

**SYRINGES.**—These have passed through various phases, from the short cross-handled concern of days gone by to the really handsome and convenient implement of the present day. No question can be entertained as to the best kind, which is of a very simple nature. The sliding valve should be made of leather in preference to its being packed with tow, and no one ought to purchase a syringe that is not fitted with a ball top; this admits the water freely, yet acts as a plug on the water being driven out, but allows this to pass in the form of a shower. No matter who may be the maker or patentee, by taking the above as a guide, no mistake can be made. Avoid all jointed and otherwise deformed editions of this useful implement. Also, avoid all such as are furnished with suction hose, &c.; have nothing to do with them, and you will escape much disappointment. The uses of the syringe are so well known, that they need not be entered into here. No greenhouse, vinery, stove, or other plant-house ought to be without one.

**WATERING-POTS** are certainly indispensable in the garden as well as in the plant-house. They are made of tin or zinc, the former being painted, but not the latter. Their size is a matter of choice, but I should say those holding about four or five gallons would be the most useful and convenient for carrying water, and smaller ones of one and a half or two gallons for applying it. For in-door work amongst potted plants, watering-pots should have rather long spouts, particularly for plants on narrow stages, but they are better and handier if the vent is not too small. A three-quarter-inch vent is small enough for any watering-pot, unless very small indeed. A small watering-pot holding about two quarts, fitted with a fine rose, is very handy for watering cuttings, seeds, &c. Amongst Pines, a pot with a short spout is very useful for watering the plants through a funnel and tube. Other watering-pots may occasionally be found useful, some fitted with a rose, others not. For watering seeds, &c., in the open ground, the large pots above named will generally be the best, the water being applied through the rose. The smaller pots are best with a rose attached, which may often be brought into requisition for small seeds. Generally there are few gardens in which the three sizes I have named will not be sufficient for all purposes, although from fancy or other reasons a man may wish for something different; but mere whims in such matters ought not to be indulged. Many a man has been led away by the notion that he could improve on a simple and effective implement, or that something of his own invention would improve matters wonderfully, and has only found out his mistake after much money has been wasted, and much material spoiled. The more common and simple form of watering-pot will be found the best, and it will be needless to look further and fare worse.

**MOWING MACHINES.**—These are now indispensable in any garden where there is a lawn. The smallest grass plat, grass edges, or grass walks between flower-beds, may be fitted with a machine, small ones about a foot or 14 inches wide being suitable for the purpose; while for large and broad lawns 22 or 24-inch machines which require two men to work them are better, or even still larger, drawn by a pony or horse. These machines are manufactured by different firms, and it is not for me to recommend those of one maker in preference to those of another. I have no doubt that all machines, if properly made, no matter who may be the maker, both work well, and are durable with care. There are, however, technicalities, which experienced men only can fully appreciate. A machine that the least jolt puts out of order on account of one or more screws not fitting properly, is, to say the least of it, vexatious; but this I have found to be the case in machines that were otherwise perfect. Makers ought to pay attention to this, as well as to make improvements year after year.

A great deal depends on the care and management of the machine itself. Many an one has been laid aside simply because a little common sense was wanting in order to see the cause of its being out of repair. Want of cleanliness is most injurious to these machines. They should always be cleaned and oiled before putting away, pegs kept in the oil-holes, the chain or cogs kept clean, and, in fact, treated as if they were, what they really are, a rather complicated piece of machinery, requiring somewhat more care both in the using and putting away than a common roller. Many

gardeners treat them, however, as if they were nothing more.

**SCYTHES.**—Although to a certain extent, the scythe is superseded by the mowing machine, still it is not driven entirely out of the garden. There are times when it would be better to mow with the scythe than with the machine. For instance: after much dry weather, when instead of close herbage the lawn is covered with bents or the flower-stalks of the grasses; and also in very wet weather when the machine does not work so well. Although it is never advisable to lay turf in such a position that the machine cannot be used, there are often places where this is so, as on steep banks, or slopes that are too steep to work the machine; the scythe is indispensable in such places. In many gardens the mowing machine has never been introduced, the prejudices in favour of old methods, and in opposition to new, not having been overcome. Strange as it may appear to the scientific gardener, I have known both master and man exclaim against the machine as a useless innovation, applauding the scythe as the only machine worth patronising on the lawn. Such antiquated notions, however, are happily the exception, for the scythe is too slow for these go-a-head days, except in cases where it is retained as a matter of necessity.

Where such is the case, it is worth while to know which kind is the best of the several that are known. As far as my own experience goes, I would not recommend any of the so-called self-adjusting scythes, or other modern improvements, but prefer the more simple, and, as I think, better style of old-fashioned scythe that fastens with ring and wedge. The choice of the blade will require a little of the knowledge of good metal, an old hand can tell the ring of a good scythe. The handle, also, is much a matter of choice. A pouch, fastened round the waist with a strap, and a good Devonshire stone, are essentials required by the mower.

**SHEARS** are both useful and necessary appliances where there is much grass. Generally two kinds will be required: the short-handled shears for clipping the sides of banks, narrow corners, and such-like places—these should be rather small than otherwise, and kept in good repair, or the work cannot be done well or quickly—and the long-handled shears which are used for clipping the edges of grass. The handiest are those which are bent at an angle of about 80°. If the shears are kept in good repair the work will be done much better than if they are allowed to get out of order. The same applies to all cutting instruments. There are also shears made with long handles for clipping the surface of the lawn without bending the back. These, however, had better be left out of the catalogue.

**THE EDGING IRON** is for cutting the edges of the lawn or grass verges when they have been trodden down or are otherwise out of form. This instrument should be used once every year, about the end of March.

**THE SAW.**—There are various forms of this instrument, said to be made expressly for various objects. I consider, however, that there is no necessity for having more than one, which may be called a pruning saw. This should have double teeth, which is best for green wood, the blade being rather narrow and about 18 inches in length. This will answer in all cases where a saw is required in pruning or cutting out dead wood, but had better not be used for sawing dry wood or logs, which would spoil the teeth for pruning. If the saw is simply used for that purpose it will last a long time without the necessity of refiling or sharpening. A large handsaw will be found very useful in cutting up logs, &c., and where there is much wood it will often be called into requisition. Instruments are sometimes made having the blade of a bill or chopper on one side, and a saw on the other, but are not generally desirable.

**THE BILL OR HATCHET.**—There are various kinds or forms of this instrument all more or less handy. That form in general use by the hedgers about London will be found the most convenient. The blade is straight, about 10 inches long, with a small hook on the back, at the end opposite the handle; it has a short wooden handle let into an iron socket. The blade is generally of good steel. This kind of bill I have found the most convenient in the garden, and though it will not be required for pruning, it will be useful to cut up the boughs as they are sawn off the trees, and make them into pieces suitable for tying up in faggots. This

bill is also useful for cutting pea sticks into the proper size and form, and, indeed, for any purpose where a bill or hatchet is required, including hedging or hedge trimming. There will, however, be a difference of opinion as to the form of bill which is the most handy, and it would be as well to let the workman choose his own.

**THE AXE** will sometimes be useful in the garden as well as in the woods. It will, however, be only in exceptional cases, such as lopping off the larger branches of trees after they have been

\* \* \* \* \*

—F. CHITTY.

[The sentence was thus left unfinished by Mr. Chitty; his death-disease seems to have deprived him of the energy needed for the completion of his task. There is a mournful interest attaches to this. It remains as evidence of a good and true man striving to be useful even when disease forbade his being active—it was his last effort, and there is a sorrowfulness attaches to the knowledge that it was the "last."

Mr. Chitty, let us repeat, has left a widow and five young children unprovided for, and we shall be glad to receive further contributions for their assistance.—Eds.]

## THE MODERN PEACHPRUNER.

No. 7.

### USEFUL MAXIMS.

1. It is essential to form the tree into two equal wings, so as to direct the main current of the ascending sap into two channels. By this means it is best mastered and held in check. The sap has always a very great tendency to flow in a vertical direction, therefore any vertical line is a difficulty in training. The consequence of a neglect of this law in vegetation is that the lower portion of a tree becomes feeble, bears small fruit, is exhausted even by this production, languishes, and dries up, while the upper branches, receiving a superabundance of sap which cannot be elaborated, become rankly luxuriant, and so produce few flower-buds.

2. In forming a tree it is an error to trust to shortening back the branches at the winter pruning. A better mode would be, during the period of growth, to incline a too strong branch to a horizontal direction, and to tie up vertically a too weak branch. Of all the plans adopted for this purpose this is the simplest and the most efficacious. The weaker branch should also be allowed a greater freedom, so that the sun and air may have free access all round it. Any shoots on the weaker branch which are to be ultimately removed should be allowed to remain on it as long as possible to attract the sap to it. The more leaves thus left the more strength does the branch gain. The contrary practice, of course, should be applied to the too vigorous branch of the other wing. Fruits exhaust the branch, as they require much sap to nourish them, therefore we should not leave too many on a weak branch, where, however, they generally soonest appear.

By a combination of these simple means the equilibrium of the vegetation of the tree may be restored during the season of growth, leaving comparatively little to be done at the winter pruning. Considerable amputations always injure trees, however well performed. The modern school especially recognise this principle, which is so much aided by the summer stopping of the shoots that little or no shortening of the leading branches is ever required. We require all the growth a tree can make; and the object proposed by shortening-in the branches, often by fully one-third of their length, so as to make the lower eyes break, can and ought to be obtained by more natural means. If we take care of the fruitful shoots these will soon master the branch. The only use of the latter is to carry the former, and these should be especially attended to.

3. If we wish to obtain fruitful shoots the branches must be left as long as possible. A contrary practice produces only excessively vigorous shoots which are unfruitful. Trees only produce flower-buds when, after having acquired a certain development, the sap circulates more slowly. The forms which trained trees are made to assume very much contribute to favour this production of flower-buds by distributing the current of the sap into diverging lines, and avoiding all vertical lines. The more these forms are com-

pleted the more trouble the sap has to circulate, and the more time it has to become fully elaborated in the leaves by the action of the light and air. The sap, converted into cambium, must also descend more slowly by each separate channel. This is a valuable aid towards the production of fruit-buds, these, probably, being produced by the descending fluid alone. Be this as it may, and the question is not as yet satisfactorily decided, all seem agreed that to a diminished circulation is owing the formation of the genuine fruit-bud. Lifting the tree, without injuring the roots, is a powerful remedy when it is too vigorous, and making rank growths. In many forms, however, which will be hereafter more fully entered into, this lifting is never necessary in Peach trees, because by summer stopping the shoots are rendered fruitful, while the roots from the close planting of the trees cannot acquire any undue development. In the orchard-house I have never lifted any Peach trees, because fertility was obtainable by the other means described. Diagonal cordon Peach trees having only short fruitful shoots on the main branches or leaders are easily restrained in vigour. The fruit are produced close to the main leaders by which they receive the direct action of the sap, and so become largest.

4. It is an axiom in Peach-culture thus to obtain the fruit close to the base of the shoots. When, on the contrary, these shoots are allowed to produce spray as well as the spurs, a number of useless flower-buds are formed which the tree has no strength to mature. The sap is exhausted by following so many needless channels, and the fruits either fall at the period of stoning, or remain small and hard. This defect is apparent chiefly in trees pruned on the "long system." On the other hand, by close and judicious summer stopping, in ordinary summers the flower-buds will be developed near the very base of each shoot.

5. During severe weather no pruning whatever should be undertaken, either of trees in the open air or in the orchard-house. The danger lies in exposing by the cut the orifices of the sap-vessels; these burst and are liable to decay. Such trees as are exhausted by their crop should be cut early in the autumn. This operation relieves the tree and aids in promoting the next year's crop. After a sunny and dry summer the wood is ripe, and should also be pruned early, for the reason mentioned above.

6. Never prune the Peach-tree much at one time. If pruned during the period of growth much sap is lost from the wounded shoots before they can cicatrise. If this occurs in the winter, that being the time for any more important change, the tree always feels it. Bending down branches even at that time is not always a safe operation, unless gradually done, because at the lower portion where the bend occurs the bark is compressed, and the sap cannot ascend nor descend there so well as it did previously. On the other hand, the upper portion of the bark is distended extremely, and there is much risk of a very strong wood shoot pushing vertically. A portion of the winter pruning should, therefore, be left for February; many shoots about which the pruner had not made up his mind may then be regulated, not to mention the numerous unavoidable accidents which occur during a whole season, and disorder all our calculations.

7. Above all, let the amateur avoid considerable amputations of his Peach trees. When he has to perform one let him cut cleanly and as close as he can to the base of the ramification.—T. C. BRÉHAUT.

**ANNUAL EXHIBITION OF THE MAIDSTONE GARDENERS' SOCIETY.**—The second annual exhibition of the Maidstone Gardeners' Mutual Improvement Association took place on Tuesday at the Corn Exchange. Considering the adverse character of the winter, and the frost which set in on Sunday evening, the plants, both as regarded their number and quality, far exceeded the expectations of the members, and the arrangements were so admirably carried out as to meet with the unqualified approbation of every one, though great things were expected this year, in consequence of the universal satisfaction which attended the last exhibition. The room presented the appearance of a winter garden, upon which had been bestowed the concentrated energies of fifty ardent horticulturists. To say that the achievement

reflected the utmost credit upon the Association, is but a small tribute to a society which has done more to elevate the gardening community of this town and neighbourhood than almost any other means. It is computed that about 1800 visited the exhibition, and the pecuniary results must consequently have justified the expectations of the members and covered the expenses attending the show. The upper decorations were principally designed by the President of the society (Mr. Robson), to whom many thanks are due. They were left till the following evening and contributed largely to the enjoyment of the visitors to the temperance *soirée*.—(Maidstone Journal.)

#### POSITION OF BEDS AND BORDERS— MUSHROOM-BEDS COLD.

I RATHER differ from the editorial remarks about the border in front of the house in the garden plan of "A. E. L.," in your Number of March 14th.

The border, B, which was narrow, was made wider, and last year it was by far the best thing in the garden. It is in front of a house which stands in a very airy and exposed situation, and it is a great advantage to the plants to have the protection from the north winds. Where old creepers—such as climbing Roses, Wistaria, Jasmine, &c., are growing against the house, they will not do well without a border, and I do not think any old house looks well without these flowering creepers against it. Is it not better in such a case to have borders and to make them broad enough to hold bedding-out plants as well as the roots of the creepers? I have always recommended this plan, and have already laid out eight or nine gardens for different friends, besides giving plans and designs for others where I have not been able to go myself, so that your adverse criticism was entirely contrary to all my preconceived ideas.

I have two or three leading theories about garden plans, one is—that each bed ought to make a perfect and uniform shape of itself; secondly, that in a set of beds the walks ought to form patterns as well as the beds; thirdly, all points and unequal-shaped beds ought to be avoided as much as possible; fourthly, if on grass all walks should be made of a nearly uniform width, and so that a mowing-machine can be worked in and out without much trouble and without trampling on the borders, so as to avoid the necessity of clipping afterwards. Thus the design in page 214 answers in my opinion all these rules; but in that at page 232, the large scroll beds are quite out of proportion, so that in order to plant it properly you are obliged to divide it into three or four members with different colours, breaking the line of continuity, and practically making it into three or four unequal-shaped beds. The bed, No. 1, and the borders on each side are good because uniform; but the scroll-beds do not answer one law—*i. e.*, they cannot by any line be divided into two equal halves, and all beautiful shapes in nature for the most part are capable of this division, as all animals down the vertebræ; leaves down the midrib; flowers by a line drawn at right angles to the corolla, &c.

Excuse this long letter! I am puzzled what to do with a Mushroom-bed. It is in a cellar, inside what was a large bin, about 5 feet by 3, the sides are brick, and it is covered with a wooden lid which fits quite tight. I put about 15 inches of droppings gathered in the usual way and never exposed to any weather. The heat rose well, and I spawned in about five days, and covered with  $1\frac{1}{2}$  inch of soil tolerably dry. All was as well as could be for a fortnight, but now the bed has lost its heat, and I am afraid has become too cold to produce Mushrooms. As it was inside a cellar and a wooden air-tight covering over it, I did not put any litter or anything over the bed, thinking it would keep its own heat. Can that be the cause?—X. Y. Z.

[It is always well to agree to differ, and differ yet agree. The longer we live the more tolerant we become to the opinions of others, and the less dogmatic we become as to our own. As a general principle we still hold to the opinion expressed at page 214, in relation to the border B. "That such borders conjure up ideas of damp and mouldiness in the walls. Such borders, and pots, and boxes there, also remind one of a town garden." Circumstances, however, alter cases. If the house is so old and its appearance

unsightly as to render covering the walls with luxuriant creepers desirable, then we have no fault to find with the broad border, and ribboning that border if the proprietor so feels inclined. No doubt the background of the climbers against the walls would shade back the colours of the flowers as well as protect them.

As a general rule, however, the fleeting beauty of bedding plants is associated with different ideas from those impressed by the solid structure of a mansion, and for a mansion of large size, we think the flower garden would have been near enough; but let every man enjoy that which gives him the greatest amount of pleasure. Allow us now to pass a remark or two in the same kindly spirit as that in which you write, as to the principles of design in flower gardens, as exemplified in the plan, page 214.

1. "Every bed ought to make a perfect and uniform shape of itself." We hardly understand this. Every single bed should be so formed and planted as to make a unique whole in itself. Every group of beds should be so formed as to make a well-balanced whole. This we presume is different from having each bed of a perfect and uniform shape of itself. What constitutes perfection in shape? We cannot beat the circle, the rounded squares might pass muster; but set out any of the rest of the beds in that group solitary, alone, and by what rules could we demonstrate that each and every was perfect in shape, or more perfect than any other shape? Of course, we are here taking no notice of the manner in which the figures of the main part of the group nicely fit into each other.

2. "Walks ought to form patterns as well as the beds." This will be done as a matter of course, but these patterns are not confined to regular geometrical arrangements. The patterns formed by the walks or open spaces in the plan at page 232, would by many be more liked than those at page 214, just in proportion as they had a finer eye for the sweeping artistic, than for the regular geometrical. We could not say which plan is the better.

3. "All points and unequal-shaped beds ought to be avoided." True, but leave out the circles and rounded squares, or flattened circles, and every figure besides, in page 214, has its allowance of sharp points. Judged by the absence of sharp points, the plan at page 232, must carry the honours.

4. There can be no question as to the desirability of all the pathways, if grass, being so made that they can be cut with the mowing-machines, and this is insured by your plan. This is one reason why most scroll patterns, as at page 232, should be on gravel.

We attach but little importance to the analogy drawn from the vertebrae of animals, and the midrib of leaves, as showing the importance of being able to divide a group of beds into two equal halves. This is desirable, but there is nothing undesirable in being able to divide the group into four equal quarters. This your plan would not permit, but the other would; and we think your plan would be improved by having the two circles (12) banded round with three clumps as in 13, so as to admit of this quartering.

We would here advance one rule in laying down a figure, which is something like a necessity to the perfection of the form of the group—namely, that you cannot take out a clump and substitute another of a different shape without destroying the balance and the harmony of the whole. Apply this rule to the central seventeen beds, and see how true it holds. Apply it to one end, 13, 14, 15, 15, and to balance you must make another end like it. Apply it to the two circles (12), and the four rounded squares (16), and what becomes of such a rule, if as rule it be received? You might do without these six figures altogether without injuring in the least the balance of the main group. You might make them of any other shape or form, and they would be equally helpless to injure farther than appear as so many excrescences. Let your two circles (12), stand, and put a band round them, as in 13, and we believe your four quarters would be better than two halves; make the four 16's, into circles and band them in a similar way, and we question very much whether the effect would not be better still. As it is, we do not see why, so far as perfection in form is concerned, the 12's and 16's should not be changed into each other, or even into such five-sided figures as 6 and 7, &c. The subject is worth ventilating. We showed how the scrolls could be more simply planted. In one word, whatever our separate opinions, we

may rest assured that those who admire graceful sweeping lines, will admire scroll patterns; and those who admire massive, easily-managed beds of flowers, will adopt such plans as yours, at page 214.

As to the Mushroom-bed; if the soil is dry, and you want Mushrooms soon, water with water of about 75°, and put a little hay over the bed. If the bed is moderately moist beneath, and you are content to wait, we have little doubt you will obtain Mushrooms as the weather, and therefore the cellar, becomes warmer.]

#### NOTES ON SOME NEW PLANTS AT MR. W. BULL'S, CHELSEA.

I THOUGHT the other day, that when I noticed some of the novelties in Mr. Bull's establishment I had had enough of new plants to last me some time; but having heard that the importations which he had expected from abroad had arrived, and that I should find some remarkable things amongst them, I took the opportunity, while in town on other matters, of running over to Chelsea and seeing with my own eyes as far as I could the treasures he had received; and as far as my poor opinion goes, I am convinced that there are many plants which will be of great interest both in a botanical and horticultural point of view. Many of them were in a condition in which it would be impossible to form a very decided opinion, while others gave evidence of their beauty and singularity.

I have already alluded to the very interesting variegated *Aucubas* received by Mr. Bull from the continent, where they were introduced by Dr. Von Siebold; but he has some green-leaved varieties which will be, I think, equally interesting, and which have already received certificates both at the Royal Horticultural and Botanic Societies. Then there was *A. japonica macrophylla*, with a light spinach-coloured green leaf fully 9 inches long by 4½ wide; *latifolia*, very broad dark green leaf, quite distinct; and *mascula angulata*, very narrow leaf. The variegated varieties were *lancifolia variegata*, margined with gold; *mascula elegans* and *mascula elegantissima*, broad leaf, yellow blotch; *mascula bicolor*, deep yellow centre to leaf; *sulphurea*, edged with sulphur yellow, the yellow also interspersed in the green; *varia*, distinct deep yellow blotch; *mascula picta*, also yellow-blotched. These are all distinct, although it may seem that in describing them as yellow-blotched and green there is great sameness; but any one can at once see the great distinctness that there is in the different varieties, and what a fine feature they will by-and-by make in our gardens.

Of new *Camellias* there were *Prince Camille*, fine shaded rose, of exquisite shape, and *Comtesse de Gonda*, a very pretty light pink flaked with deep crimson, promising to be a very pretty variety. Then there was an older kind—*Mrs. Abbey Wilder*, a beautiful white, but interesting from the fact that *Queen of Beauties* is a fixed sport from it. Some of these new varieties of *Camellias* are quite putting the older ones into the shade.

*Ferns*—that ever-increasing family whose name now is legion, and some of whose members are ever arriving from different parts of the world—were well represented by *Adiantum robustum*, a splendid strong-growing kind of fine foliage; *Lastrea erythrosora*, a hardy and pretty species from Japan; *Odontosoria tenuifolia stricta*, differing from the normal condition of the plant in having stiff upright foliage; *Ophioglossum palmatum*, a very handsome species introduced in dried specimens, it is said by one of the best authorities on the subject, two hundred years ago, but of which the only living example is that which Mr. Bull has; a very beautiful *Asplenium* called *myriophyllum*, which will make a companion plant to *Todea superba*; and a fine *Aspidium*, not yet named, from Para.

Of fine-foliaged plants, suitable, perhaps, for sub-tropical gardening, such as Mr. Gibson has so successfully carried out at Battersea, there were some plants which will make a figure I fancy by-and-by. These were two *Solanums* of great size, and indeed of great names—one of them, at least, for it was called *S. pyracanthum horridum aureum*! deep golden-yellow spines; and *Solanum crinitum*, of which the leaves were 2 feet long by, in their widest part, the same

width: this had white spines, but both promised to rival the *Wigandias*, *Ferdinandias*, and other plants of similar character now used. Of those which might be more correctly designated as stove plants there were some fine things. Thus there was *Saurauja sarapigiensis*, with a broad *Sphærogynelike* leaf, the leaves measuring 19 inches long by 8 wide; the midrib being of a bright carmine, and the rest of a lighter shade of the same colour; when well grown this will be a noble-looking plant. Of a somewhat similar character was *Sphærogynne cinnamomea*, of which the stem, ribs, and under surface of the leaves were of a bright cinnamon colour. There were also a fine *Cupania undulata*, of graceful-pendant habit; and a new species of *Leea*, of a beautiful drooping habit also. *Pandanus*, which has so many ornamental species already, was represented by *Pandanus Lennæi*, somewhat like *elegantissima*, but with white spines; and curiously enough the spines in the midrib turn downwards while those on the edge turn upwards. With this there was *Pandanus Vandermeerschii*, a fine delicate leaf with white spines, a sweetly pretty variety. And what shall we say to a bright sky blue *Amaryllis*? This I did not see in flower; but in *Imperatrice des Brazils* Mr. Bull possesses such a glorious subject! Its flowers are said to equal in size *Ackermanni* and others of the same character, and to be a genuine bright blue.

I ought to mention, too, a plant which will be interesting to many from the associations connected with it—*Salvadora persica*, the Mustard tree of Scripture, and which Mr. Bull has already announced for distribution. *Allamanda Hendersoni*, said to be the very finest of its class, is also here in Mr. Bull's possession, and promises to be a great favourite.

And now, as ladies are said to reserve the pith of their letters for the postscript, so have I reserved to the last mention of a very curious, and, as far as I could judge, a very beautiful tribe entirely new to us—viz., some new *Urospathas* from South America. They belong to the *Aroideæ*, the leaves having somewhat of the curious winged character we see in some of the members of that family, but still more fantastic. They differ from *Alocasias* in two very important particulars—instead of having bulbous roots they have long creeping rhizomes like some of the creeping Ferns, and instead of being deciduous they preserve their foliage all the winter—a very decided advantage. Then this foliage is marked in a most beautiful and singular manner. In some there is a red ground netted all over with green, others have a creamy white ground interspersed with green, others are blotched with red, and in fact it is hardly possible at present to say what strange forms and colours they will present; but I think enough is seen to enable one to say that they will indeed prove one of the most decided acquisitions in ornamental-foliated stove plants that we have had for some years. When I add that the entire stock of many of the most prominent and beautiful of the preceding plants are exclusively in Mr. Bull's possession, those interested in such things (and who are not?) can form some idea of the treat in store for them by a visit to his establishment.

And so must end my notes. Will any one wonder after seeing all this, and having the words "new," "novelties," &c., ringing in my ears, that when I "turned in" for the night my dreams should have been coloured by what I saw?—that I fancied Mr. Bull was clipping off the few hairs I had left in my rapidly decreasing locks, and was inserting them in thumb-pots, and dosing them with "thine inimitable oil Macassar," as an entirely new sort—that my digits were expanding into creeping rhizomes, while all over me there was a general sprouting process going on which threatened to exhaust all the tissues of my poor body—and that an admiring bery of botanists were minutely surveying my poor self, and disputing as to what new genus they should ascribe me to. Unhappily I was not in my own home, so that I had no kindly nudge to startle me out of my visions by "My dear, you must have eaten something that disagreed with you;" so that it went on until I was heartily glad to awake and find, as old John Bunyan hath it, Behold it was all a dream.—D., Deal.

**LARGE PICEA PINSAPO.**—In your Numbers of February 28th, and March 7th, correspondents describe the size of specimens of that noble Conifer, *Picea pinsapo*, growing at

Luton, and at Woodlands, Redhill, respectively, 42 feet in circumference, and 14 feet high; 44 feet in circumference, and 19 feet high. It may be interesting to know that a fine specimen is growing here which measures 24 feet in height, and 54 feet in circumference round the branches at the ground and for two-thirds of the distance up, the tree thence forms a cone to the summit (the latter grew 2 feet long last summer above the uppermost tier of branches); it thus assumes a cylindrical form, ending in a cone. Doubtless there are other specimens of it in the United Kingdom, which for size outstrip this.—W. GARDINER, *Eatington Park, Stratford-on-Avon.*

### MY ORCHARD-HOUSE

Is now passing out of bloom; there has never been such a fair promise of fruit before, and this is the eighth season. Our numerous visitors display an undiminished interest in the hundred varieties of the choicest Peaches and Nectarines in existence, now so beautiful. The season has been backward but shows signs of change. The equinoctial gales came from the N.E., a sign of a dry summer.

Not sufficient account is taken of the difference of colour in the flowers of the Peaches and Nectarines in classifying them into two divisions of large and small. At any rate colour forms an unerring guide, and an observer will discover many distinct shades, all indicative of parentage.—T. C. BRÉHAUT.

### NUMBER OF WORKING HOURS FOR GARDENERS.

FROM your article with the above heading I rather differ, I am of opinion that when gardeners are paid their full wages all the year round, which is my case, they should not be over-nice when the work is pressing, and the days are long. I feel confident that my man for many days together, and that frequently in the winter, does not do work worth 9s., when his wages are 18s. per week. I think both master and servant in such cases should give and take. For months in the winter there are not ten hours daylight, and for some time only from eight to nine, when the dinner hour is taken out. Even if the weather is suitable a man can do little towards earning the wages he is paid; and of this I feel confident, if a gardener knows work is greatly required to be done, and will remain occasionally an hour or so longer, he, in the long run, loses nothing by it, but, on the contrary, gains greatly in the esteem of his employer, and in many other ways.—A MANY YEARS' SUBSCRIBER, near Birmingham.

[You say that you differ from us, though we, in the main, do not see clearly where the difference lies. We also advocated the give-and-take principle as to time, and even advocated the propriety of the gardener not taking without the knowledge and sanction of his employer. In thorough contradiction to the old proverb, that "stolen waters are sweet," we believe that in the end they are very bitter, and hence have contended that for a gardener ever to enjoy a change or a holiday thoroughly, he must have that holiday with the sanction of his employers. In all such cases as yours, however, where much is expected in summer, to make up for the short days of winter, it will always be advisable not to trust to any custom, &c., but to have the terms explicitly stated. This would at once prevent unpleasantness, so long as the mutual relations of master and servant continued. Though we give this opinion under the circumstances, we do not thoroughly agree in your conclusions.]

1. A gardener out of doors in winter is placed in much the same position as other workmen, who receive the same pay as in summer, because there is much more discomfort in doing work at that time, and also because the employer knows if he did not so give employment in winter, he would not be able to get the labour he wants in summer. This fact applies to a gardener merely as an out-door labourer, and where he has no glass or plants under glass to attend to. Even then there are numbers of jobs that may be done in bad weather, and thus permit of more straightforward

work in good, suitable weather. But if the gardener has glass under his care, his position is very different from that of the labourer or the mechanic, whose work is finished when darkness comes. Then, often, the anxieties of the gardener are only commencing, and often will he be going to work when his neighbours are going to bed. Even in such a case, by banking up fires, whether they are wanted or not, he may save himself trouble after evening, or greatly reduce it, but in that case, at the expense of his employer's fuel heap. In many such cases where economy is practised, a winter such as this last is much harder on the gardener than the general summer work.

2. Though we agree with you, that working a few hours longer, when work wants doing, will be no injury to the gardener, and may often command the esteem and good offices of his employer (and almost every gardener we have known, would do so without receiving any hint as to its propriety, more especially when kindness on the one hand becomes the most powerful means for evoking gratitude and fidelity on the other)—still agreeing with all this, we think it necessary to state, that the more intelligent and imbued with self-respect a man becomes, not only will he be more faithful to his employer, but he will also be more anxious that his services shall be remunerated in the shape of wages, as a matter of right, so long as the agreement lasts, instead of defective wages, being made up "in many other ways" as a matter of favour, and next door to a matter of charity. Not but that a kind present whets the zeal and activity of a man; what we want to remonstrate against, is the self-satisfaction produced in the donor from giving as a matter of kindness and of bounty, what ought to have been given merely as a matter of justice.

Again, we say nothing as regards those whom no number of hours would satisfy, we allude to such readers as are perfectly reasonable in the matter, and who merely think a gardener may give a few extra hours work now and then, when particularly required. On that we are all agreed, but we wish it to be clearly understood, as the result of much observation and experience, that continued long hours for any length of time, will not only impair the physical energy of the worker, but they will be of no benefit to the employer. Once, or twice, or oftener, in a week at times, is all very well, but only let a man continue for some weeks—say from five to eight, and even with extra nourishment, he will soon do less than if he worked from six to six. We have noticed that this would be the case even when the men thought they were doing their best, and were anxious that they should make their labour tell. Even then as a matter of profit to the employer, we believe long hours continuously to be a delusion, and if the men do not live well, we believe that they will be a direct loss. Now and then is a different affair.

And, lastly, without anything like a reflection on our correspondent, we suppose that there will always be many who will consider that from 9s. in winter, to 18s. in summer, will be sufficient to repay the gardener for all his anxieties and cares. True, there will always be great numbers of places where the proprietor only requires a good garden labourer for his garden, and who will find him more suitable for his purposes, than if he had a man of greater accomplishments. We need not here stop to prophesy about the "good time coming," when to make the most of small places greater intelligence and greater wages will be required. We point broadly to the fact, that such is not the case now, and to that fact we respectfully solicit the attention of the Council of the Royal Horticultural Society, who are laudably endeavouring to produce a race of *great horticulturists*, by ensuring that young gardeners shall be men of great and general intelligence. We say advisedly, that however well meant, the whole scheme now, as heretofore, will be a "delusion and a snare," unless the Council so bring their influence to bear as to convince the owners of gardens of the propriety of employing such accomplished men, and the necessity of giving them a much advanced rate of remuneration. We will ever advocate the young gardener's improving and educating himself, and gaining knowledge in every field, partly that he may be able to hold a good place when he obtains it, but chiefly for the pleasure and the happiness that knowledge based on moral principle will ever bring to its possessor. We shall have more faith in examinations

and diplomas, when we see these valued by employers, and some greater and general prizes held out in the way of remuneration.]

"A LANCASHIRE LAD" has written his ideas on this subject, but little can be added in reply to what was said at page 233, and to-day in answer to a correspondent who thinks that gardeners should work long hours in summer to make up for short hours and unremunerative labour in winter. Stopping for tea is not general, and could not be practised where the gardener does not live close to the garden; but when he does so it will be a great help to him, especially when he contemplates working for some time after six o'clock. "A LANCASHIRE LAD" must be a young gardener, and it may be well to say in the way of caution that young men have been injured by working too long without refreshment. As to the other two ideas—first the advocating the working half an hour later on five days of the week, in order that these half hours may be taken back again on Saturday, carrying out such an arrangement must be wholly a matter of agreement. In many establishments this would answer admirably; in others it would not suit at all, where all hands are often required to finish up work on Saturday, so that no unnecessary labour shall be performed on the Sunday. Where there is much glass, and a great deal of plant culture in pots, Saturday would be the most unsuitable day of the week for a holiday; but, as already stated, that is no reason why the gardener should not have a holiday as well as other workmen, whether they work with head or hands, or both.

The other idea involved in the question, Why cannot a gardener take a half-holiday without being obliged to ask for it? just shows the futility of continuing such a discussion, as no expression of opinion would be binding, as every proprietor of a garden, and every manager of a large garden, will still reserve the right of deciding as to the order and the mode in which they shall be served. If that mode savours of the grinding and despotic they will in due time perceive their error. It is best for all parties that there should be a clear understanding, instead of depending on custom among other workmen who, take time to themselves when they think proper, and without condescending to consult or ask any one. Surely "A LANCASHIRE LAD" must have some little idea how these independent care-for-nobody men get on in life. He must know that when a slack time comes they are the first to leave from yard and factory, and even in brisk times they are often told to pack up their tools, as the employer cannot afford to pay rent for empty benches. I will stand up for reasonable rights for our order, but I contend that what is worth having is worth a clear mutual understanding. Let gardeners in small places, and under-gardeners and labourers in large ones, act on the "Lancashire Lad" principle and farewell to everything like system and order. Employers who, like another correspondent, may think they overpay their gardeners in bad weather in winter, may have some reason for grumbling if, after such payment, they find that instead of attending to their interests their servants look after their own business and their own pleasure in the fine working days of spring and summer. No! no! that is not the way to secure kind considerate employers and faithful industrious servants.—R. F.

[We have received more letters from young gardeners urging their "right" to a Saturday half-holiday, and one says that they are not treated with sufficient consideration because they have no "union." We sent one of those letters to Mr. Fish, and the foregoing is his reply. To all that he, an old gardener alive to the interests of his craft, has said we fully assent, and we will add that no master would retain an under-gardener who urged his "right" to a half-holiday, for he has no more "right" to one than have his employer's grooms and coachmen. Suppose they claimed half-holidays as a right! As for want of "union" among young gardeners, if it is meant that they should combine and "strike" to effect their desires, we, as their friend, can only hope that they will never be so very blind to consequences. Head skilled gardeners are not easily replaced, but those in their pupillage would have successors found without such difficulty.—EDS.]

## ROYAL HORTICULTURAL SOCIETY.

WEEKLY SHOW.—APRIL 1ST.

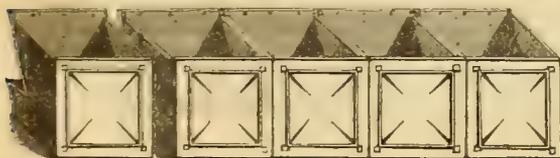

On this occasion Mr. Bull sent a small collection of Camellias, striped Azaleas, *Medinilla magnifica*, a small plant of *Alocasia Lowii*, *Bertolonia margaritacea*, the leaves beautifully studded as if with pearls, *Arisæma ringens purpuratum*, *Anthurium leuconeurum*, his fine *Imantophyllum miniatum*, *Sauromatum guttatum*, *Cineraria Attraction*, with a broad white ring margined with bright rosy purple; and specimen plants of *Astrocarum mexicanum*, and *Lantana rubra*.

Messrs. Lee, of Hammersmith, also sent Camellias, *Medinilla*, and *Boronia pinnata*; Mr. Catleugh, Chelsea, *Cytisus*, *Pelargoniums*, and yellow Azaleas; Lady Caroline Legge, a small plant of *Hymenophyllum tunbridgense*; and Mr. Coysh, gardener to E. Wood, Esq., Rugby, three plants of *Dielytra spectabilis*, in excellent bloom; also, seven Azaleas, all in good bloom, one specimen grown as a bush, being particularly good. Accompanying these were two *Statices*, and very good plants of *Adiantum cuneatum* and *pubescens*.

Mr. Kilminster, gardener to Mrs. Seaton Laing, sent three stands for dinner-table decoration; also, a flower-basket filled with white Azaleas, Camellias, *Deutzias*, and other spring flowers. Messrs. Lucking & Greeves likewise contributed flower-baskets, bouquets, &c. Lastly, from Mr. Meredith, came his Black Alicante Grapes still in excellent preservation; and from some one unknown some very good specimens of *Beinette du Canada*, *Blenheim Orange*, *Adams' Pearmain*, and other Apples.

## HAYMAN'S REGISTERED ALBERT VASE FLOWER-BOX.

This newly-invented vase flower-box differs from the old flower-box in its capability of being taken to pieces, and the parts used separately as vases, or together as boxes.

These are by a simple contrivance attached together, so that they cannot be blown down. There is also another and far greater improvement in the mode by which water and air are admitted to the roots.

It can be used for decorating the table, hall, or can be placed on brackets, or in conservatories, in verandahs, or in-doors for flowers in the winter. The old form of boxes are too heavy to be removed readily, and are comparatively useless during the winter.

They have a very ornamental appearance, being made of zinc with ornamental plate glass, or Minton tiles placed in front, and japanned all round. They are calculated to last for many years, and are inexpensive compared to the old boxes.

## CULTURE OF FIGS IN POTS.

I am growing Figs in pots, in a heat of from 70° to 80°. The plants are small, but in 13 and 15-inch pots. How thick may I allow the fruit to remain? It is now on some branches as close as 3 inches. The Figs are about 3 inches in circumference—Brown Turkey, and White Marseilles. I cut through each terminal-bud as directed in your Journal (February 23rd, 1864, page 158), and I find some of the buds do not start again at present. Will the Figs on these branches without terminal shoots come to perfection.—C. P.

[You are growing your Figs in a great heat, and must give water in proportion; only let them once be dry, and the

fruit will fall. The Figs will swell very fairly without the terminal-bud. You must have nipped it through well back, as it has not pushed. We would take off a few Figs before the second swelling.]

## ONION CULTURE.

In the Journal of the 7th ult., under "Work for the Week," it is recommended in making Onion-beds to raise them 9 inches above the ground level. Surely this must be a slip of the pen? In light soil, with such a season as the last, it would be next to impossible to obtain a crop on beds of that description. As the system of growing Onions practised here has been very successful, I send you a brief description of it.

In the first place, I may state that until ten or twelve years ago the crop was annually almost destroyed by the Onion grub. To prevent this I have not found anything equal to charcoal, applied as follows:—Before sowing-time a quantity is pounded and sifted through a half-inch sieve; the quarter of ground intended for Onions is then well trodden; the drills are drawn 1 foot apart and 1½ inch more than the usual depth, which extra depth is filled up with the prepared charcoal, on which the seed is sown in the usual way. Since we adopted this plan, with one slight exception, the grub has not troubled us.

I do not claim the invention of this system. I have only improved upon the original, which I had from an old brick-layer who was noted for growing good Onions. His practice was to collect all his hedge clippings and other brushwood, to char them, and dig all into his Onion-bed. To this he attributed his success.—H. P., *Elsham Hall*.

[Mr. Keane directs the bed to be raised 9 inches to allow for the treading and rolling, which consolidates the soil.]

## SATURDAY HALF-HOLIDAYS FOR GARDENERS.

We think you have signed your somewhat rhapsodical and poetical letter very properly by appending to it "Youthful folly and discontent." There is such an amount of intelligence underlying it that we question very much if you have obtained much relief by "making a clean breast of it." We have no belief in reliefs in any trouble or difficulty unless they are based on what is just and right. With a sense of what is right as we think strong in your nature, we can hardly see how you could be otherwise than discontented with yourself, when in such a stormy afternoon you could make a cogitating stool of a reversed large flower-pot, instead of using your hands in the very simple work of picking discoloured leaves from bedding *Geraniums*. The work merely required a little of the eye and the quickness of the hand, and but little of the mind, so that you could easily have worked and thought on other matters too. You might have told "discontent" to be gone if you had just thought of poor fellows working out of doors. Our happiness depends more on the way we look at circumstances than the circumstances themselves. The advocates of improvements and reformations should show they are fit for and worthy of the improved position. What would never be advanced as a boon to "folly" may be freely given to prudence and integrity.

From what we have stated in answer to other correspondents it will be seen that we are no advocates for long hours of labour. We think it advisable to leave a little earlier on Saturdays, if possible, than on other days. Holidays themselves at times are very desirable, and are beneficial to employer and employed, and we believe all the more when not looked upon as matters of "right," but of mutual understanding. We have stated why in some cases Saturday would be the most unsuitable day of the week—otherwise if employers should approve of some of the men having some hours that day there could be no other objection. The time may come when there will be much shorter hours of work in all days, but that is not yet, and we must take matters as we find them.

Our correspondent wants to know why young gardeners cannot be treated to the Saturday half-holiday as well as

tradesmen and mechanics. Well! first because they are more servants than mechanics, and we hardly think the time has come when the gentry will neither ride nor drive on a Saturday afternoon, in order that grooms and coachman may not be disturbed. Secondly, because not bales of cloth, nor bars of iron, nor planks of wood, but in many cases tender living existences, demand the gardener's care, and would soon perish without it. On this account extra care and extra attention are demanded on the Saturday, in order to minimise, as much as possible, labour on the Sunday. We personally know of cases in which the attempt was made to let a part of the men away earlier on the Saturday afternoon, but it was found to be too hard on those who remained, and leaving all together an hour or so earlier was found to be more satisfactory.

Thirdly, if carried out, we do not see how visiting other gardens, a very desirable thing, and which our correspondent assigns as a reason, could be satisfactorily accomplished on such Saturday afternoons, when no more men would be employed than were absolutely essential to perform the necessary work. Who could pay the necessary courtesies to the visitors? Even now, without such holiday, visitors on a Saturday afternoon could scarcely come at a worse time, unless on a Sunday, and this latter we would, unless in very exceptional cases, wholly forbid.

Without speaking of head gardeners, we have no doubt

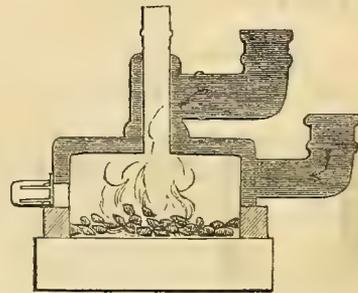

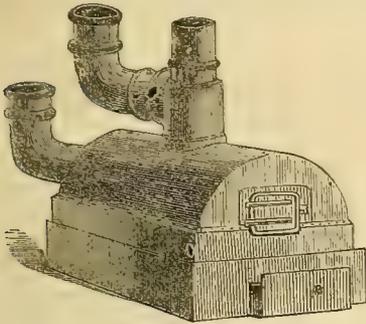

that all young gardeners who are industrious, prudent, honest, and attentive, will never be begrudged a few hours, or more at a time, to see other gardens on other days comfortably. Of course we do not include those who sit and think when they ought to work and think.

Here we would stop, without taking notice of the "want of will" of employers and head gardeners further than directing attention to the letter of Mr. Wills, page 244, so far in unison with our own ideas as expressed at page 234, but our correspondent alludes to "want of union amongst journeymen gardeners." We believe there is a hazy feeling of this kind afloat, but the sooner it is dissipated by the light of stern facts, like mists before the light of the sun, the better for all concerned. It is unnecessary to say a word on the right of combination, or the awful evils often flowing from the practical assertion of such rights; it is sufficient for our purpose to say that journeymen gardeners could do nothing in such a case by union, simply because other workers would soon willingly do, or try to do, what the journeymen refused to do. In one word, were even a general practice as to hours more uniform than now, the best plan would be to leave all such matters to the mutual agreement between employer and employed. The ventilation of the subject may help to lead to such an understanding as would combine, if possible, increased generosity on one side with increased faithfulness on the other.

### PORTABLE BOILERS.

ONE of the most desirable things that could be introduced would be some contrivance by which one could turn a piazza

from a nice shady summer promenade into a conservatory or winter garden at pleasure.

There would be no difficulty in doing this were questions of heating out of the way. There have been contrivances of the kind attempted, introducing the necessary warmth from heaters, but this kind of heat is never satisfactory to plants. If pipes could be so arranged as to be readily put together, and taken apart, and put away, one difficulty would be got over.

The boiler question, we think, could be settled by the use of Myer's portable boiler, of which the above is an illustration. No doubt this idea could be still more perfected, as all first-hand inventions can. We have not seen one of the boilers in use, but judge from appearances it will be all its maker claims for it.—(*American Gardeners' Monthly*.)

### FRENCH VERSUS ENGLISH ASPARAGUS.

MR. WATSON may relieve himself of any doubts he may entertain as to my good intentions. I never doubted his statements, nor had any intention of wounding any one, native or foreign. My opinion was asked as to the merits of Asparagus grown on the English and French systems, and having grown that vegetable on both systems in England, the opinion given was based on the results. These were: The heads grown on the French system were longer, entirely white, except the tips, and though 9 inches in length no more was eatable than a small portion of the growing-point; the Asparagus grown on the English system was not so long, was not so fine-looking, but more of it was eatable, and consequently it was in most request by the family; there were endless complaints about the Asparagus being woody so long as that grown on the French system was served, but it was pronounced excellent after being allowed to grow to the same length as ordinarily.

Perhaps Mr. Watson is not aware that the first shoots of Asparagus are much more tough than those produced later

in the season, and that forced Asparagus is much more tender than that grown in the open air. This may explain why French Asparagus can be more tender than English, and I have not the slightest doubt it generally is so, both being grown on the same system. What French Asparagus I have eaten has certainly been more tender than English-grown, but I never found any equal to that with but 2 inches of it uneatable. My experience is that but the upper 2 or 3 inches are eatable, therefore Mr. Watson has been more fortunate.

M. Carlos Forer's letter is simply an explanation of the reasons why we find French Asparagus purchased in Covent Garden, or at the hotels and restaurants of Paris, is not so good as that eaten where produced, he being so good as to admit that some amateurs even in France "maintain that that with green ends is preferable to the rose and white." That is precisely my opinion of that grown in England.

The reason French Asparagus is worth so much more in London is that it is several days, to say nothing of weeks,

earlier than our own, and being grown naturally is finer than our forced. Having a warmer climate it grows quicker, and it cannot but be more tender than ours.

Mr. Watson need not suppose me to be a professional horticulturist, but make sure of it. I have made my way in a garden since I was twelve years of age, having learnt from nature more than I ever did from man, and having gleaned a fact noted it.—G. ABBEY.

### WINDOW GARDENING FOR THE WORKING CLASSES.

On Tuesday evening last a lecture on window-gardening was delivered by W. S. Bosanquet, Esq., to a very crowded audience of the working classes in St. Margaret's School-room, Westminster. The chair was occupied by Vice-Chancellor Sir W. Page Wood. After a few introductory words from the Chairman, Mr. Bosanquet commenced his lecture, which was sustained throughout by a fluent and graceful delivery on the part of the lecturer, and listened to with breathless attention by the large audience, who appeared to drink in every word as it fell from the speaker, testifying in no unmistakable way their interest in the subject. Mr. Bosanquet having expatiated on the advantages derived from the cultivation of flowers—its soothing and humanising influences on the mind, and its sure indication of a cheerful and well-ordered household, he proceeded to inform his audience of the great Show that is to take place in the garden of the Royal Horticultural Society at South Kensington on the 10th of July, to which an invitation has been sent to every parish in the metropolis to compete for prizes offered by the Society. He urged upon his hearers not to be discouraged because they might fancy that somebody else would be there with something that would beat theirs. If they did so they could never expect to attain to any degree of perfection in the cultivation of flowers; but their object should be to do their best, and concentrate all their attention on some common and easily cultivated flower which they found would succeed in the locality where they lived. It was not the rare and costly exotic that would take the prize that day, but a carefully-tended Fuchsia or Geranium, or some such flower.

The lecturer then went into the subject of cultivation, and laid before his audience very clearly and simply the practice they must follow for the successful growth of window plants. He began first with the flower-pot, and told them the first thing to be attended to was to see that the pot was perfectly clean, for flowers loved cleanliness as well as they did or ought to do; and the next was to see that there was sufficient drainage to the pots, for that was another condition that plants liked as well as human beings did. Then some very sound instruction on watering was given, instruction that many who consider they know something about the growth of flowers might derive advantage from. The maxim impressed upon them was never to give water unless the plant wanted it, and then to give abundantly. The plant never fails to give indication when it is athirst; the soil on the surface of the pots becomes dry, or partially so, and the leaves begin to hang down, and their cry for water is as loud, if we could hear it, as would be the cry of any individual in the audience if they too were in want. Then cleanliness was urgently brought before them. Mr. Bosanquet showed that plants could no more continue to live and to thrive if their leaves were covered with dust and dirt than could human beings if their mouths were stopped with putty. It behove them, therefore, to see that the leaves of their plants were kept perfectly clean by being either sprinkled with water or cleaned with a sponge. Then air was an indispensable requisite to plants, but care should be taken in giving air to plants in rooms not to keep them in a draught. The door and window should never both be open at the same time, for that was another point in which plants resembled themselves—they could not exist in a draught.

At the conclusion of the lecture several of the audience put questions, asking information on some details connected with the cultivation of plants in rooms and windows, which showed the strong desire they had to make themselves acquainted with the subject. Before the meeting separated the Vice-Chancellor made an application of the subject in a religious point of view, and reminded the audience of the

parable of the sower, which our Saviour delivered to his disciples, and after an impressive exhortation to the audience the meeting separated.

### VINE-BORDER ON A CLAY SOIL.

I AM about to erect a vinery on a site where I am obliged to fill up to the depth of 4 feet for both house and border. The foundation is stiff clay, and I want to keep my Vine roots out of the clay. Would it be preferable to fill up the 4 feet with rough clinkers and cinders from a factory furnace, and make my border on this; or would you fill up with clay, and concrete above, and then make the border? If so, how am I to proceed, as I am ignorant of the process and material used for concreting? The border will be 34 yards by 4 yards, the size of the house.—T.

[In such a case we would prefer filling up 18 or 24 inches with clinkers, on these place some 2 or 3 inches of the finer clinkers and ashes, beat and roll well, so as to have a firm surface, and if not firm enough without, place a little of the clay among them at the surface. On this place 3 or 4 inches of concrete, made by mixing together three barrowloads of the roughest small cinders, three of rough pebbly sandy gravel, and one of quicklime, working it up quickly with just enough of water, and laying it down, smoothing it, and then rolling it, when it will become very hard. On that place about 15 or 18 inches of clinkers, and then 20 or 24 inches of soil. Have a drain below the concrete in front. We advise the above to prevent the roots going down through such a depth of clinkers.]

### FROGS DESTROYERS OF WOODLICE.

INQUIRIES are often made for the best mode of destroying woodlice. I have never seen the employment of frogs advocated. They are quite as useful as toads, and more easily procured. They should be supplied with water, and unless food is abundant, should be occasionally fed with worms. Some of my poor frogs were starved for want of this knowledge.—B. A.

### TRIOMPHE DE RENNES AND OTHER ROSES.

MAY I ask Mr. Radclyffe what stock his Triomphe de Rennes Roses are on? I cannot make it grow at all. It scarcely exists here. As soon as a shoot is made and has pretty well run its length, down fall all the leaves. I think I understood Mr. Cant, that he found it difficult to succeed though, I think he said, with Mr. Hedge, it flourishes admirably. Mr. Radclyffe speaks highly of Duc de Rohan and General Washington. Now, out of doors the former does not open one bud in twenty here, and neither in nor out of doors can I obtain one bloom in fifty of General Washington fit to look at; in fact, I shall throw both away after this summer, unless they do better than they have hitherto done.—P.

[Triomphe de Rennes, many trees, are on the Briar, and also on Manetti. It is an excellent doer. It is never out of bloom. It never has a blind end, or a defective bloom. The whole frontage of my house is lined with these excellent, ever-blooming, yellow Roses—namely, Solfaterre, Gloire de Dijon, Triomphe de Rennes, Celine Forestier, and Mdlle. Aristide, the last is chiefly an ornamental Rose. A south wall is best for Triomphe de Rennes, but I have successful plants in advance of, and also against, a west wall. I have also most successful plants of it in my north-east garden, unprotected, on the Manetti stock. It does there equally well with Gloire de Dijon. All down my south fruit wall, I have trees of Gloire de Dijon, Triomphe de Rennes, and Celine Forestier. I have no better trees, and am never at any part of the season, beginning in May, till frost and snow set in, without a profusion of these noble yellow Roses. Triomphe de Rennes, on the Manetti, is all heights, from 6 to 12 feet high. It rarely suffers from mildew or blight. Taking all points into consideration, I believe it to be the best yellow Rose in existence. It is of the best quality, and if shaded, of a fine golden yellow. "P.'s" land is strong and cold. He must lighten his soil with leaves, ashes, or heath soil, and then Triomphe de Rennes will go a-head. Such trees require little pruning, rich soil, free drainage,

lots of water, and a West Indian sun. My trees fill the air with tea scent.

"P." complains that Duc de Rohan, Maurice Bernardin, and General Washington, do not open freely. That is their tendency. If he will throw up banks like those on which Thorn hedges are planted, put these Roses on the banks, and give them plenty of water in hot dry weather, they will open as easily as Safrano, though they be as large as a man's fist. Washington in character is a fall Rose, and does good service after others have done their work. The other two bloomed well in numbers last season on the flat. Still the Roses on banks beat similar Roses on the flat. I never saw finer Roses than the blooms of Duc de Rohan, Maurice Bernardin, and Charles Lefebvre, which is a free bloomer anywhere. Add Senateur Vaisse, also a free bloomer, and you have the four best crimson Roses in existence. The leaves of Triomphe de Rennes fell, probably, from the soil binding and want of water. Honeydew prevailed much last season. Did they suffer from this? As soon as you perceive it you must syringe it off before it becomes an immovable viscous concrete.—W. F. RADCLIFFE, *Tarrant Rushton, Blandford.*

## PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

*ALOCASIA LOWII* var. *PICTA* (Variegated Low's Alocasia).—*Nat. ord.*, Aroideæ. *Linn.*, Monœcia Monandria. "A more highly coloured and variegated variety of *A. Lowii*."—(*Bot. Mag.*, t. 5497.)

*LÆLIA PRÆSTANS* (Admirable Lælia).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria. Native of the Brazilian island St. Catherine. Prefers a block of wood. Flowers rosy lilac, opening in November, and very durable.—(*Ibid.* t. 5498.)

*IREESINE HERBSTII* (Herbst's Iresine).—*Nat. ord.*, Amaranthaceæ. *Linn.*, Diœcia Pentandria. Introduced by Mr. Herbst, Kew Nursery, Richmond, from the River Plate, South Brazil; but it is also native of North Brazil and Peru. It is a most striking coloured-leaved plant, the colours being intense plum veined with purplish crimson.—(*Ibid.*, t. 5499.)

*AGLAONEMA MARANTIFOLIUM* var. *FOLIIS MACULATIS* (Variegated Maranta-leaved Aglaonema).—*Nat. ord.*, Aroideæ. *Linn.*, Monœcia Monandria. Native of Malay Islands. Leaves dark green marbled with greyish green.—(*Ibid.*, t. 5500.)

*ACROPERA ARMENIACA* (Apricot-coloured Acropera).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria. Native of Nicaragua.—(*Ibid.*, t. 5501.)

*ACHIMENES*.—*Pink Perfection*, rosy pink; throat yellow spotted with orange. *Grandis*, pale purple with orange, spotted throat. Raised by Mr. Parsons of Welwyn.—(*Floral Mag.*, pl. 233.)

*VARIEGATED VERBENA*—*Popular*. Flowers scarlet; leaves variegated with yellow. Raised by Mr. Bull, King's Road, Chelsea.—(*Ibid.*, pl. 234.)

*CHRYSANTHEMUMS*.—*Golden Ball*, bright orange, with golden tips to the petals. *Venus*, lilac, with paler-tipped petals. Both raised by Mr. Salter, Versailles Nursery.—(*Ibid.*, pl. 235.)

*BEGONIA DIGSWELLIANA*.—Flowers light pink, with darker edges. It is in the nursery of Mr. B. S. Williams, Holloway.—(*Ibid.*, pl. 236.)

*WAITZIA GRANDIFLORA*.—This is one of the species of those flowers popularly known as "Everlastings." "It is very nearly related to the *W. aurea*, but is more robust, and has flowers considerably larger. The foliage, too, is so much less villous, that, when planted together, the species are readily distinguishable from each other by this feature alone. It blooms rather later than *W. aurea*, coming into flower when the latter is almost over. I received this fine species from Dr. F. Mueller, of Melbourne, but have reason to believe that, like the other species I have described, it is a native of Swan River. From its robust, tall habit, it is better suited to the open ground than to pot culture, agreeing in this respect with *W. aurea*.

"The treatment requisite for all the species may be concisely summed up as consisting of thin sowing about the middle of March; early preliminary transplantation to pots or boxes; close approximation to the glass, in a moderate temperature only, to prevent weak growth; and final trans-

plantation to the open ground in May, in the case of *W. aurea* and *W. grandiflora*, or to four-inch pots in the case of *W. acuminata* and *W. corymbosa*, with a subsequent shift, if found necessary. Both the latter may, however, be submitted to open-air treatment in light soils. In wet ones, or if exposed to heavy or long-continued rains, they are liable to die off without apparent cause. The treatment recommended is, in fact, simply that requisite for most of the half-hardy annuals; and, although it may appear to involve an attention to details which many amateurs are unwilling to give, it cannot be too strongly urged that any attempt to cultivate on the 'rough' system will infallibly result in disappointment.—W. THOMPSON, *Ipswich.*"—(*Florist and Pomologist*, iv. 42).

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

TAKE every opportunity of eradicating weeds, hand-weed where practicable, as it more effectually answers the purpose than hoeing and raking when the soil is moist. Cut the Box-edgings, and keep the walks well rolled. *Basil*, a warm sheltered spot may be chosen to sow in the open ground, but being a rather tender annual, it is generally the best plan to sow in pans, or on a slight hobbed, and afterwards plant it out. *Beans*, earth-up the early crops, but before doing so lay a little soot close to the stems, as before recommended; timely earthing will also prevent the wind damaging them. *Borecole*, make a sowing for the first crop: what is commonly called the Scotch Kale is the best variety. *Broccoli*, most of the varieties may be sown in the end of the week; by sowing early there is time for a second sowing in case of failure. *Cabbages*, fill up any blanks from the reserve-bed, at the same time stir the soil between the plants and earth them up. *Carrots*, thin-out those sown in frames, and give a good supply of water when dry. In sowing the main crops put in the seed rather thickly, as it is more liable to fail than any other kitchen-garden crop. *Celery*, the main sowing for the winter crop should now be made. Continue to prick-out from the early sowings, and pay attention to air and water. Clean and earth-up any that has stood the winter, as, if it is of no other use, it will do for soups. *Cucumbers*, keep a brisk heat in the beds as the days lengthen and fine weather approaches, bearing in mind that light and heat should be proportionate to each other; give air daily, and keep the lights free from dirt. If green fly or thrips appear, recourse must be had to fumigation, which will generally extirpate them. *Lettuce*, give air to the plants in the frames night and day in mild weather, loosen the soil about those planted under hand-glasses. *Onions*, sow the Silver-skinned for pickling on a poor piece of ground. Plant into beds the autumn-sown or those sown in boxes in the early part of the year; draw shallow drills, and lay the roots of the plants in them at regular distances, after which cover them lightly with fine soil. *Peas*, sow any approved sorts for succession. *Radishes*, keep up a succession by sowing a few once a fortnight. *Sea-kale*, remove the covering immediately it is done with; if there is any yet remaining to be covered let it be done before it grows much. *Turnips*, thin-out those sown in frames, and give them water when necessary.

### FRUIT GARDEN.

Complete the pruning and nailing of wall trees, and protect the blossoms. Remove suckers from Gooseberry bushes and from all fruit trees as soon as they make their appearance.

### FLOWER GARDEN.

Repair displacements of soil or gravel on slopes or precipitous walks with as little delay as possible, for every shower will widen the channel. Gravel put on sloping walks should be almost in a state of mortar prepared for use; well trodden and afterwards rolled, it forms a hard and durable walk. It is often desirable to keep Ivy close to a building against which it clings; in that case it should be defoliated every year about this time, and it will again speedily be covered with fresh and vigorous leaves. Shrubberies should now be gone over, pruning-in encroaching branches and removing dead and dying limbs. The late heavy falls of snow have been by no means congenial to the roots of Tulips; in fact, unless the beds are situated on a porous subsoil or well drained, it is attended with posi-

tive injury. Particular attention must be paid to those whose foliage is cankered, cutting it away to the quick with a sharp knife. As soon as the beds are perfectly dry the surface soil should be carefully stirred. No time must be lost in getting the stock of Carnations and Picotees potted off. This is a good time to strike cuttings of Pansies; put them in round the sides of small pots, plunge in sand on a north border, and cover with a hand-glass.

#### GREENHOUSE AND CONSERVATORY.

See that nothing suffers from drought. The larger specimens in tubs or pots, if any, must have a liberal supply, provided the drainage is complete. This is the period for the free use of liquid manure, but take care that it is perfectly clear and not over-strong. Large Orange trees are very fond of it. Pay due attention to the watering, shifting, and stopping of plants in general. Many conservatories are very unfit places for Heaths, being generally too lofty and kept too warm for them. Some of the free-flowering varieties are, however, very ornamental, and should be largely employed in their decoration during the early months. As soon as they have done flowering let them be pruned back, and give them a liberal shift when they start into growth, using good fibry peat for the purpose, and if they are attended to in the growing season, they will overcome any injury they may sustain through occupying an unsuitable position while in bloom. As more than ordinary fires have been required of late in plant-houses, rendering the internal atmosphere drier than usual, the requisite humidity should be supplied by sprinkling the heating apparatus, floors, &c., at the same time keeping it below rather than above the usual standard for this season, to meet the present low temperature. Hardwooded plants, of which the pots are full of roots, and which it is not convenient to repot just at present, should be carefully attended to with water, for if allowed to flag many plants, particularly such as have fine hair-like roots, scarcely ever recover.

#### STOVE.

Much attention is necessary at this period to growing stock. Much progress may be made in a little time by a judicious course of culture. Shut up with a high temperature rather early in the afternoon, and use the syringe rather freely. Make cuttings as soon as they can be obtained, of Geissomerias, Plumbagos, Eranthemums, Justicias, Clerodendrons, Vincas, Euphorbias, Brugmansias, Begonias, Thunbergias, &c., in order to keep up a succession of clean young stock. See that growing Orchids have abundance of atmospheric moisture with a liberal circulation of air early in the morning, shutting up close betimes, and taking care to observe moderation in the use of fire heat, in order that a pure atmosphere for the night may be insured. Growing Dendrobiums will now require liberal supplies of water, and let the plants on blocks be frequently syringed.

#### DUNG-BEDS FOR VARIOUS PURPOSES.

At this period it is of much importance to have a dung-bed or two of a very moderate degree of heat for the purpose of cooling down fresh-struck cuttings, hardening annuals, and receiving plants from either the stove or greenhouse; for in consequence of liberal shifts in these departments and the rapidly increasing size of the Pelargoniums, Cinerarias, Calceolarias, and Fuchsias, something must be removed, and a cold frame is insufficient for some of these tribes. Let, therefore, any spare frames at command be fitted up, using a little well-wrought dung, with a good deal of tree leaves if at hand. A steady bottom heat of 70° will be sufficient, and very little material will suffice to produce this, if some coarse litter of any kind be packed closely round the frame after the bed has been formed. Such frames should be watered with scalding water as soon as a little heat is up, this will destroy insects and their eggs. A coating of ashes may then be spread over the bed, and the frames matted up at night for two or three weeks, leaving a little air all night to plants hardening off.—W. KEANE.

#### DOINGS OF THE LAST WEEK.

##### KITCHEN GARDEN.

PLENTY of snow on Tuesday and Wednesday, but a south wind on Thursday, from which we fondly hope that gentle April will come to us, and bring sunshine and mild breezes.

Very little has been done on the ground out of doors. The snow has acted as a protection from the keen frosts; and most fruit-buds are so backward that but little harm would be done if the birds would only let them alone for a few weeks. Stirred up the surface-soil among forward Peas in pots; watered with warmed water some of the Tom Thumb kind, planted out in orchard-house. Put a few Sangster's No. 1, out of turves, thinly in the front of the house; and these we will allow to ramble a little, and stop when the shoots show a few flowers. Turned out turves with Peas sown in them, placed among forward Potatoes, as they were beginning to be too forward, and placed them in a turf-pit, where a little protection can be given them, until the weather become more mild. Turned out a lot of Cauliflower from pots into an earth-pit, where a little protection can be given them. Stirred up the soil among those under hand-lights, and protected with a little litter in the frosty nights, as we wish them to go on now without check—a check from hardening them with frost now being apt to make them button prematurely. Removed the glass from those in frames, and covered in severe nights with hurdles having spruce branches drawn through them.

All these doings make lots of litter, but at this season it is hardly possible to combine the extreme of neatness with the extreme of economy, and a little roughness may well be excused when the object and the utility are at once perceptible. To keep all neat and orderly round lots of earth-pits, &c., would now be almost as endless and expensive a job as washing an Ethiopian white. Those who make neatness an object, must go to the expense of covering that makes and needs no litter.

Took up a little more Sea-kale and Rhubarb, and to secure variety, put some Swedish Turnips into a dark warm place. When the tops have grown 6 or 7 inches in length, though yellow, they make a dish fit for an epicure. Made another piece of a Mushroom-bed, having taken the old out. All our pieces have done first-rate, except a bit that should be coming in now, and that is behind its time; and we are a little doubtful of it, as the material was too old, and too wet, and would have been benefited if a truss or two of dry straw had been cut into one and two-inch lengths, and mixed with it. The next piece will, however, soon be in, and the older pieces yield gatherings.

A good portion of the time has been occupied in covering and uncovering, making tallies, sharpening sticks, washing pots, and putting them clean in bins, where, however, their stay will be short at this season, and cleaning and mending glass, &c. A little management will always secure plenty of such work in bad weather; and it is ever the reverse of economy to have men working out of doors in wet weather, to say nothing of the unkindness and inhumanity of making them do so. We shall never forget how a foreman led us mowing on a cold wet day in the end of autumn, until we might as well have been dragged through a river, every advancing step we took sending the water gurgling over the tops of our shoes. He could change his clothes, and have his wet ones dried in his rooms, but nearly all the rest had to go a good distance to cold fireless lodgings, and consider themselves well off if their clothes became dry in several days. We noticed then what we have often noticed since—that after such a water bath the men went about their work for some days afterwards as if they had neither life nor energy for it. That day's work we always regarded as a direct loss, instead of gain, to the employer.

##### FRUIT GARDEN.

Much the same as last week. Have done nothing out of doors to speak of owing to the weather, as we had protected Peaches and Apricots even before nailing. The work will come all at once; but we have no doubt there will be every alacrity to carry it out. Tied up Vines, regulated shoots, and drew a dry hand over the bunches coming into bloom. In some cases held a sheet of paper below the hand to catch any pollen, and threw that, or placed some on the hand which we drew over irregular setters, as Sweet-waters and Muscats. In such a house the night temperature has averaged 60°, and the midday temperature, without sun, 70°, with sun up to 75° and 80°, and little fire heat if there was plenty of sun. A very little air was only given at the top of the house, and even that little would have been less but for Strawberries.

In a small pit, the earth part being about 3 feet in width and 15 inches deep, we have an extraordinary show from Vines that were put out last season and cut down. We know very well if we allow the half or the quarter of the bunches to remain, the Vines will be pretty well exhausted. In the same pit, but in three lights separated by a division, are old plants of Sweetwater which have borne heavily for a great number of years, and have just the same amount of soil, which we think must now be somewhat exhausted. These also seem a mass of bunches, though not large. Below the soil, among clinkers, are two small pipes for hot water, but we have not top heat enough to bring the Grapes in very early; but when we have it, we have no doubt that, in these six-foot-wide pits, we could have early Grapes very economically, as the glass could be easily covered at night. These Vines are now somewhat crowded, and we must clear the pits somewhat to give them room. First, there was a mixed collection of plants as soon as the Vines were pruned; then, as soon as the Vines began to move, a rough stage was placed across it for Strawberries, and, beneath the stage, seeds of Lobelia, &c., were sown in pots, and covered with squares of glass. The seedlings, when fairly up, were removed to where they could receive more light; and now we must move a good portion of the Strawberries, to obtain full light and room for the Vines. This is a specimen of the cramming mode which has to be resorted to in many cases, and which, whilst it makes the most of glass space, greatly increases the labour, and keeps the eye and contrivances of the gardener constantly at work.

We have noticed a few more of the brown beetle on shoots in the Peach-house, and of course did not see them long. Our young man thinks nothing is so effectual as soft soap water, and so long as it is used weak enough not to injure leaves or young fruits we have no objection to its use. It is always a good plan to adopt measures that are even thought to be best, and hence one man will make a mode answer perfectly when another man entirely fails with it. It is but natural for us to like our own plans best. A man has a peculiar mode of doing a certain job, which he is convinced is the best mode, and at least he does the work well. You may think another mode would be better, and say so, but if you insist on going against the man's conviction you will not be much of a gainer thereby. Every good workman, be he even a garden labourer, has pet ways and methods of his own, and if these do not go to the extreme of interfering with general order and arrangement it will generally be best to let him work in his own way. Provided we never catch a sight of this ugly brown beetle we shall be very careless as to whether we owe the riddance to soap water, tobacco water, quassia water, or any other water. We fully believe that an attentive eye and an active hand are, after all, the great securities against all such pests.

In the first orchard-house, where an iron stove had been a little used last season, two trees in the centre are coming into bloom notwithstanding all our care with air on, except in severe frost, to keep them back. The other house will not open just yet. As a further security against fly and beetle we purpose syringing all trees of which the buds are not opened with a liquid consisting of about 1 lb. of Gishurst and 1½ lb. of soft soap, and a little sulphur and lime water, mixed up in thirty gallons of water. We shall also let a little fall on the floor and pots. We should not like to use it stronger at this season, and we will put it on very gently, so as not to displace the painting round the swelling and now opening buds. Last season, though but little troubled, we detected by this time some of these beetles running races on the tops of the pots, so that most likely, in addition to the syringing, we shall paint the parts of the pot above ground with some nasty substance which will not dry fast, such as soft soap. Any little trouble now that will keep such enemies from appearing during the summer will be advisable. We saw but little of this beetle last summer, and hope to see less this season, but of all pests in a garden it is the very worst—green fly and even red spider are a trifle to it.

#### ORNAMENTAL DEPARTMENT.

Chiefly potting, making use of stokeholes with sheds over them for the purpose. The potting was chiefly confined to Gloxinias, Gesneras, Caladiums, &c., and to potting and

turfing faggots of bedding Geraniums. The fine-foliaged Begonias, Gloxinias, &c., were set on a stage, where they would be well shaded by the Vines. It is better, however, when they are not placed there until after the Vines are done flowering, as the smallest particle of extraneous matter, be it the flowers of the Grape or a bit of decayed leaf, resting on the leaves of these fine-foliaged Begonias for a few hours, or even less, is sure to make a hole in the fine leaf; they do best, therefore, in the shade where nothing can drop on them. As to the faggots of Geraniums, we described how they were closely packed in 10 and 12-inch pots in the end of autumn. We have just now filled four lights of a six-foot-wide pit with plants in 60-sized pots, taken from some dozens of pots of 10 inches in diameter, stuffed with Bijou. Hardly one had failed out of very nearly four hundred. These did not require a tithe of the attention during winter that small fresh-struck plants did. We like in general to pot or turf the variegated ones, though Bijou and Alma lift very well from an intermediate bed of rough earth and leaf mould. These old plants are rather top-heavy for the turfing process. We resort to it because scarce of pots, and also for saving labour afterwards. For small plants struck late in autumn from 3 to 3½ inches square of turf and from 2½ to 3 inches thick will be quite sufficient. The tougher the turf is the better. If we take it up 12 inches wide, it is cut on the bench into square pieces with a sharp hand-bill, and then the earth part being placed uppermost, a hole is scooped out nearly to the grass with a knife, and about as quick as pots can be brought and drained. A little nice light soil is put in the hole with the young plant, and if a little bottom heat can be given the roots will soon be hanging like hairs round the sides of the pieces of turf. When turned out in beds the turf goes along with them, and this is found to be an advantage if you wish to lift with anything like a ball in autumn. Without any bottom heat, those who are afraid to plant out of earth-pits at once, or who cannot afford time to water pots, may try the turf system, placing the bits close together on the bottom of a pit or frame, or on the floor of a late vinery or Peach-house.

Proceeded also with cuttings of Verbenas, and whatever else was likely to be wanted. To oblige some inquirers we will here shortly allude to a few matters very simple but very important to success.

1st. All cuttings of such plants strike most speedily in sweet bottom heat—that is, if placed on a sweet hotbed, though Geraniums and many other plants will strike as well on a shelf as anywhere.

2nd. All cuttings will strike quicker if there is the beginning of spring growth on them before they are taken off.

3rd. The cuttings should never flag or be wetted before they are inserted; and as soon as inserted they should be taken at once to their position, so as to prevent any flagging afterwards.

4th. The success as above will greatly depend on keeping the cutting that has commenced to grow on the parent plant still growing slowly, as when separated from it; and the best securities for this are additional heat, a close moist atmosphere, a little air at night, and just as much sunlight as the cuttings will bear without flinching, and then, if the sun distresses them, a little shade or a skiff from the syringe.

5th. Bear in mind that shade is a necessary evil, tending to weaken and enervate plants and cuttings, causing the latter to elongate upwards instead of rooting downwards, and thus wasting the stored-up supplies instead of supplying the plant with new sources of vigour. As little shade as possible should be given, removing it, not at the approach of night but as soon as the sun is clouded.

6th. As giving ease every way, the propagating of all bedding plants at this season will be best effected if the cuttings are placed about 20 or 24 inches from the glass. With the use of the syringe in sunny days little shading will be needed unless in very bright sun, as the force of the rays is broken before they reach the cuttings.

7th. Light sandy soil with abundant drainage is best for striking. A very little very rotten leaf mould, or heath soil, may be added, but leaf soil at all rough and fresh is apt to produce damp and mouldiness.

8th. These things kept in mind, it matters not a pin what the vessels for cuttings are, whether pots or pans, soft or

hard-burned, semicircular tiles, old tin and zinc spouting, or old worn-out evaporating-pans of similar metals, especially zinc.

9th. The chief time that such cuttings, without the help of bell-glasses, hand-lights, &c., but exposed in the bed, need syringing, &c., is in the middle of sunny days, when the evaporation of their juices is going on at the greatest rate. If such a skiff from the syringe will-do, it is a much better practice than shading.

10th. All cuttings, of which there is a doubt of any insects being on them, should after they are made be drawn in little bundles through tobacco water or quassia water, holding the ends in the fingers, so that the cut ends may not absorb much or any of the liquor.

11th. In making the cuttings, remove the leaves at the lower joint, cut clean across through the node, or just below it, and if you remove no more leaves, shorten and lessen the larger ones. We have little faith in raising such plants as Geraniums from leaves, though the leaves will make roots. To obtain plants we should like the leaves to have as much of the stem as would include a bud at its axil. That, however is just a cutting. Plants that make tubers and bulbs may be raised from leaves, as Gloxinias, Gesneras, Begonias, &c.—R. F.

COVENT GARDEN MARKET.—APRIL 1.

Out-door vegetables, in consequence of the late severe weather, are only brought in limited quantities, and Asparagus, Kidney Beans, and other forced vegetables, are no more than equal to the demand. Continental supplies, however, have improved. New Potatoes are to had at from 2s. 6d. to 3s. per pound. Apples are still brought in large quantities, among the best for the dessert at present are Court-pendu-Plat, Golden Winter Pearmain, Golden Harvey, and Nonpareils. Of Pears the supply is small, the kinds being Easter Beurré and Beurré de Rance; Pines scarce; Grapes sufficient for the demand. Forced Strawberries consist of Keens' Seedling, Carolina Superba, and Black Prince. Of Broccoli there is hardly any to be had.

TO CORRESPONDENTS.

\*\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.

N.B.—Many questions must remain unanswered until next week.

STRAWBERRY-HOUSES (Mr. K.).—The subject, we think, has been enough discussed.

SUBSCRIPTION (C. E.).—We think that by the charter and bye-laws of the Society you are legally bound for this year. On paying your subscription the Secretary will send to you your tickets.

MIGNONETTE TREE.—"M. D." will be very much obliged by any information respecting the Mignonette tree, a shrub which grows to a very large size in India, the flowers and scent similar to our common Mignonette, with the addition of sharp spines upon its branches.

TEMPERATURE OF VINERY (W. J. Watson).—The keeping your Vines to 55° until they broke had reference chiefly to the artificial heat by night. In such a case in a rather dull day, you might let the temperature of the house rise to 60° or 65°; but with sun heat you may let it rise to 70° or 75°. When you expect the sun to shine brightly you should let your fires low, and then you would not require to send such streams of cold air through your house. Fire heat and sun heat act very differently. See "Doings of the Last Week" lately.

CRANTUREA CANDIDISSIMA GRUB-EATEN (Ignoramus).—The grubs were too much destroyed to enable us to determine their species. We would give the plants a good smoking, then syringe them well with clear lime and soot water; and if that did not settle the grubs we would cut off the large leaves affected, as, to all appearance, the plants will be strong enough to push out plenty of healthy young foliage. Unless for specimens in pots, the plants will be none the worse of a partial disleafing.

REMOVING VINE LATERALS (J. Mackenzie).—We would not lessen the laterals until the fruit was colouring, and we wished to ripen the wood; but if you want such large bunches you must be content with something like half of what you are now taking. Such heavy crops, also, in time exhaust the Vine. In the rods so thickly studded we should think a bunch every 15 or 18 inches would be ample, or even fewer, if fine specimens are desired. We are greatly pleased to hear of such success in a large span-roofed house so far north as Inverness. What fuel do you burn?

ASPECT FOR CONSERVATORY (J. D.).—All things considered, the south aspect will be the best. You can keep the house cool by plenty of air. We would advise rough plate for the roof, and then you would only require blinds for the front. You might even daub the lights in front with milk and a little flour in the end of May, and wash it off in October. The site will be of great use in winter. You may have the Vine on the roof, and if you trained it in front, in summer it would do instead of shading. An east or a west aspect would do very well. A north one would save all these drawbacks, but the plants would not grow well in it. You would have to bring them in to bloom, and then remove them to be grown elsewhere.

FUCHSIA GRAFTING (An Amateur).—The Fuchsia may be grafted at any time, and almost in any manner, when heat, moisture, and a little shade can be given, and the wood used is thoroughly ripened. In such a case as yours, with merely a cottage chamber, with the window facing the south-west, the following will be aids to success:—The stock should be beginning to grow, and be in advance of the scion in growth. The scion should just be breaking its buds, and the wood should be well ripened. Young wood will do very well if pretty strong; but when we used to graft we often used some 2 inches of a young shoot, with about 1½ inch of the older wood behind it, making a slice long enough in the side of the shoot to place the old and part of the new wood on it. The slice from stock and scion must be taken off with a clean sharp knife. Tie carefully with bast, daub with a little clay, cover with a little moss, and damp that frequently.

PLANTING FLOWER-BEDS (Gertrude).—We had answered your last letter before receiving the present. We think the flower-beds are in their right place. We also think that your arrangement will be improved, and be more in unison with the quaint-looking character of the house, by your substituting the central figure in the plan, p. 232, on each side, instead of the group of diamonds; but then of course your great diamond in the centre is quite out of character. You might make the diamond about half the size, and, instead of joining the points, leave about 2 feet of an opening, and have a circle at each point. Your simplest plan would be to make a central figure much the same as your two sides, and then take a lesson for your circles from the end of these cross figures, giving the circles four bands instead of three, something in the same way, but with bolder sweeps than shown in fig. 16 in the plan at p. 214. The central figure or group we would then fill with scarlet, white, and blue. This arrangement would not give you a regular group, but there would be a fitness and fitting-in of one clump to another which your present plan lacks. You will find much to help you in the able criticism of the two plans referred to, and remarks on that criticism in the present Number.

GROWING ATRIPLEX RUBRA (C. M. C.).—We think you will have a more regular row of the Red Spinach by sowing under protection, and planting out when a few inches high. It does very well, however, when sown about the middle of April where it is to remain, and if there should be a few vacancies you can easily transplant some from where the plants are too close together. When all the plants are transplanted from a bed the lines will come more uniform, and the transplanting helps to make the plants more dwarf and bushy.

HEATING A SMALL LEAN-TO GREENHOUSE (G. T. C.).—Your best plan would be to have a small flue below the floor, as described by Mr. Fish several times. The cheapest would be a small iron or brick stove, with a pipe leading out of the house, or into another chimney; the first is best. See answers to correspondents a few weeks back. For such a house we would have a foot-shelf, or more, in front, a two-foot path, and a stage 5 feet wide behind; or you might have the path down the middle, and a three-foot stage on each side.

PROPAGATING LILIUM GIGANTEUM (E. Cooke).—This Lillium is propagated by taking off the young suckers, which come plentifully around the old stool at the time of potting, potting them singly in pots sufficiently large to hold them comfortably, and growing them on in a cold frame or greenhouse. This is best done early in February, when they are on the point of starting into fresh growth. Turfy loam from rotted turves one-half, and the other half equal proportions of turfy peat, leaf mould, and sharp sand, well chopped and mixed, but not sifted, make an excellent compost for this, and, in fact, all the Lily family.

GRAFTING CAMELIAS (S. W. C.).—April is a good time to graft them, the scion being taken from plants not in active growth, the stock placed in a temperature of 55° from fire heat, and the pot plunged in a hotbed a week prior to the date of grafting. The stock is best not headed down quite close to the scion at the time of grafting, but it should be shortened to a few inches above the graft, to attract the sap into the graft, and by shortening in part forcing it into the graft. After the graft has taken, it is necessary to cut the part of the stock above the graft quite close to the union. Your young stocks may be grafted when they are equal in thickness to that of the grafts.

SENDING SEEDS, &c., BY POST (A. L.).—If you take Letts & Co.'s very excellent and useful "Monthly Postal Almanac," price 1d., it will tell you the days the mails are despatched, the postage, &c.

**VINES BREAKING—STOPPING BLEEDING IN VINES—TEMPERATURE FOR AZALEAS AND CAMELLIAS (E. C.).**—When Vines are breaking they should have a temperature of from 45° to 50°, and be sprinkled morning and evening with sired water. When they break the temperature should be increased to 50°, in another fortnight to 55°, and when in leaf it should be increased to 60°, with a rise of 10° by day without sun, and from 15° to 20° with sun and air. The bleeding of the young Vines may be stopped by searing the ends of the rods with a red-hot iron, and then dipping the ends in boiling pitch. If pruned quite close you will lose the uppermost eye by this process. The cause of bleeding is pruning too late or not soon enough. Do so in future immediately the leaves have fallen. A temperature of from 55° to 60° is proper for Camellias and Azaleas to make fresh wood, and a moist atmosphere.

**CERASTIUM TOMENTOSUM FROM SEED (J. C. N.).**—Prick off the seedlings an inch or two apart in boxes, grow on in a frame or greenhouse until May, and then harden off, planting out in May or early in June. It will make a nice edging this year by April.

**COREA SCANDENS VARIEGATA CULTURE (G. E.).**—Sow any time in April in pots filled with any kind of light soil not pressed in too tightly. Sow thinly. The pots should then be partially plunged upon a genial warm bed. You lost your young plants by allowing them to remain in the seed-pots so long after they were up, and there was not sufficient heat for them after they came up. On the second day after they were up they should have been pricked off into fresh soil, taking care that it was quite as warm as the soil they were growing in. If 48 size pots were used for the purpose, ten or twelve plants should have been pricked in around the edge of the pot; then after they had made the third pair of leaves they should have been potted singly into small pots. Want of early attention to the pricking out young seedling plants is the cause of so many complaints of nurserymen supplying bad seed. After pricking out the plants they should be placed in a temperature of from 70° to 75°. After the second potting the temperature should be reduced to 55° or 60°.

**LAPAGERIA ROSEA CULTURE (Idem).**—It may be sown at once in a mixture of peat, leaf soil, and silver sand. Before sowing the seed it should be steeped for six or eight hours in lukewarm water or milk. The seeds should be sown thinly in pots or pans, taking care that the seed is at least 2 inches below the surface of the soil. The pots should then be placed in a warm greenhouse or pit, where the temperature would range from 45° to 60°. As soon as the young seedlings appear they should be potted singly in small 60-pots, and placed in a close pit or frame for a week or two till established in their fresh quarters. They should then receive the same treatment as greenhouse plants; but after they have become strong enough to bear it, they will require abundance of water.

**STRINGING GERANIUMS—LANKY SPECIMENS (Agnes).**—Do not syringe Geraniums and Pelargoniums at all in these cold, cloudy, frosty mornings—that is to say, if you have excluded frost. In fine sunny weather you may syringe Scarlet Geraniums if you like; but no Pelargoniums, florist or fancy, should meet the sun with wet foliage—it is a fruitful source of spot, &c. The damp will do no harm to the Vines that will now, we presume, be beginning to break; but as they progress a drier atmosphere in dull weather will be desirable, or you may have mildew. As you do not care about cuttings it would be as well to leave your lanky Geranium alone, and plant them in the centre of beds. At this early season, and with your greenhouseinery, if you wished nice plants for dwarf beds, we would cut them back some 6 or 8 inches from the pot, as no doubt they would break well, or you may plant obliquely in May; but recollect what Mr. Fish said last season as to how such exposed stems were so much more liable to be injured by frost than those that stood upright in the usual way. We think your black turf or peat used for burning would be too expensive for cutting up to make turves for bedding plants as a substitute for pots. Some peat so sold is rather sweet, but a good deal is so astringent that the plants would not root well in it. See the subject alluded to again in "Doings of the Last Week" of to-day.

**INSECTS DESTROYING FUCHSIAS (E. H.).**—The insects doing this mischief are the young larvae of one of the field bugs (Phytocoris sp.). Their habits are quite similar to those of the aphides, except that they do not breed so rapidly and remarkably. They must consequently be treated in the same manner as the green fly.—W.

**APRICOT SPRAY (J. H. Toadmorden).**—The branches, or rather spray, of Moor Park Apricot which you sent have no fruit-buds on them. The wood is not sufficiently ripe to produce fruit-buds. We should think from their appearance that the trees from which they were taken had been summer-pruned, and that the branches you sent had grown after midsummer. This is often practised, and the loss of the crop to a great extent is the consequence. This plan is often resorted to for the sake of neatness. As few as possible of the first shoots should be cut or stopped; they should be laid in, and the principal pruning should be left till the winter. A western aspect is mere suitable, and where there is a good circulation of air the trees should be planted very shallow. The soil most suitable for them is a strong loam. We shall shortly enter more fully into the proper details necessary for the successful cultivation of the Apricot. We should think the trees in the orchard-house have not been sufficiently exposed during the past summer and autumn. The pots should be placed in the most exposed positions after the crop of fruit has been taken from them.

**NAMES OF PLANTS (A Broadlyre Subscriber).**—Apparently Begonia scandens, but the specimen is insufficient.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending April 1st.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.
			Air.		Earth.				
	Max.	Min.	Max.	Min.	1 ft. deep.	2 ft. deep.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THE APPOINTMENT OF POULTRY JUDGES.

As no one has attempted to disprove any of the statements contained in my former letter, I think it will not be out of place in me to ask the members of the Poultry Club if they think it right, considering their rule prohibiting any dealer from judging, that one of the most extensive dealers in the country should continue to hold the office of Steward. In justice to the dealers excluded by this rule, this gentleman ought to resign his office; and I have no doubt that he will immediately do so, for he must see that his continuing to appoint the judges is virtually a breach—it may be an indirect one, but it is still a breach—of the very rule he professes to uphold.

The gentleman to whom I refer is Mr. Henry Beldon, who advertises that himself and daughter are the owners of the most successful poultry-yard in the kingdom. Now, when it is considered that the daughter is a child—I believe not more than ten or twelve years old—it becomes pretty evident that her ownership of the yard is, to say the most of it, merely nominal, while Mr. Beldon is the real exhibitor of the birds, although the catalogue often states Miss E. Beldon. (I have no idea what object he has in showing in his daughter's name. It is a ridiculous practice; but even this, like other ridiculous practices, has found its imitators). This circumstance is an additional reason why Mr. Beldon

should give up his Stewardship; for, should he continue to hold the office, ill-natured persons may say that the reason why his yard is so successful is because he is one of the persons who appoint the judges. Now, whether such is the case or not, it would not be altogether pleasant, and I think Mr. Beldon will do well to avoid it.

There has been a great deal said at various times about the best method of choosing a poultry judge, and many suggestions, both good, bad, and indifferent, have been made; but none worse, nor so bad by a long way, as the one now adopted by the Poultry Club.

Can any one give a satisfactory reason why two or three interested exhibitors should appoint the judge for a show, numbering, perhaps, hundreds of exhibitors, in preference to the gentlemen who have had all the trouble and expense in getting up the show, and whose interest it is to see that the prizes are awarded fairly, in order to secure the continued support of the main body of exhibitors, on whom it may be said the society depends for its very existence? But I would have all committees introduced into their schedule a rule which I see has been wisely adopted by the Beverley authorities—"That no member of the committee be allowed to compete for prizes." If poultry committees would only appoint the judges themselves, and obstinately refuse to receive any suggestions on the subject from Poultry Club, Club steward, exhibitor, or any other person, it would be by far the best plan they could adopt, and the one most likely to inspire exhibitors with confidence, and insure a continuance of their support.

With regard to Mr. Douglas there can now be only one opinion, when it is considered that, besides having the birds claimed in his name, he also received the money produced by the resale of the birds, minus a small amount owing to the purchaser for prizes.—A LOOKER-ON.

#### POULTRY AND EGG COMPANY.

By nature I am a timid and cautious man, and dread to see my opinion appear in print, I feel, however, I must make an exception in favour of Mr. Geyelin, whose interesting articles on poultry-breeding, published in your valuable Journal, I have read with much pleasure and advantage. For some years past I had an idea of breeding poultry on a large scale, but the dread of becoming the laughing-stock of my neighbours in case of failure has hitherto deterred me from doing so. When I saw the advertisement in your Journal for the formation of a Poultry-breeding and Egg-preserving Company I determined to come up to London and see Mr. Geyelin, with a view to elicit full particulars, as I consider that such a company would, if formed, supply me at a trifling risk with such practical information as I could not expect from personal experience at a much greater outlay.

Mr. Geyelin has very kindly explained to me his plans, his mode of keeping accounts, and feeding. In fact, he has given me such ample and satisfactory explanations that I feel in justice bound to say that if ever a plan appeared to me feasible it is that of Mr. Geyelin. The solution of the problem whether poultry can be bred as profitably in England as on the continent is of national importance; it behoves, therefore, all persons who take an interest in poultry-breeding to contribute to some extent towards the expense of making the experiments. I, for one, subscribe for ten shares of £5 each, and let the result prove even a failure I shall still consider it a good investment, as it will have been the means of obtaining at least some valuable information; but should it, on the other hand prove a success, it will confer a great benefit on the country. There are opportunities in life which, if allowed to pass, may never present themselves again under such favourable circumstances. At the present moment there is a gentleman, not only willing, but able, to make the experiment on scientific principles, and whose statistics, if kept according to the plan I have seen, will be so precise as to become most valuable to every poultry-breeder. If we lose this opportunity shall we ever have the like again?

In conclusion I must add that I felt very much surprised at Mr. Geyelin's reply to my question whether all the shares had been subscribed. I give his own words:—

"I was induced to incur the trouble and expense of promoting the formation of this company by many gentlemen who offered to take some hundreds of shares, as you will perceive by those letters, but to be candid, I have, as yet, had application for a hundred shares only, although upwards of three hundred prospectuses have been applied for, and unless I receive more public support the matter must fall to the ground."

Shall it be said that Englishmen are so little enterprising that we prefer to purchase in foreign markets rather than ascertain at a trifling individual expense whether we cannot supply our own wants in the shape of eggs, poultry, and rabbits?—A SUSSEX FARMER.

**SUFFOLK POULTRY SHOW.**—The Committee have made a liberal prize-list this year, and augmented the number of classes. The Brahma Pootras are divided into two classes—light and dark—and a silver cup is offered for the best. An extra silver cup is also given for a Game class. The Hamburgs are this year divided into four classes—last year there were but two. A "Selling" class and a Pigeon class have also been added. The Committee, we are told, received high commendation from exhibitors last year for the care taken of the birds, and their promptness in despatching them home again.

My SILVER PHEASANT laid on Sunday the 26th for the first time.—H. R.

#### MR. DOUGLAS.

I SEE by your last Number that the "TIMID EXHIBITOR" has at length found courage to publish his name, although it has been known to myself and most of the large exhibitors for some time. In his last letter to you he says, that perhaps I shall alter somewhat in my tone after reading the straightforward and honest letter of Sir St. George Gore. I still, however, maintain that I neither bought, sold, nor derived any benefit from the sale of the pen of birds, although the money did pass through my hands. With regard to Mr. Newsome's compassion for me for lending my name to the purchaser of the fowls, I should be only too sorry not to oblige a friend, either with my name or money, in so simple and straightforward a transaction; and I only hope that my name has been too long and honourably known amongst true poultry-breeders and the public to be damaged by the insinuations of such a man as the "TIMID EXHIBITOR."—JOHN DOUGLAS.

[All the above may be true but it does not justify Mr. Douglas acting as a purchaser. No judge should purchase either for himself or others until after the exhibition has been opened to the public.]

#### PIGEON LAYING FOUR EGGS IN FOUR DAYS.

LAST Wednesday evening a hen Powter was given to me. She had cross-paired by accident with a Fantail. On the day I had her, she had laid her first egg in every sense, being quite a young bird. I brought her home late in the evening with a Powter cock, which had also been given to me, and with whom she paired the next day. On Friday, as I expected, she laid her second egg, but being in a strange loft and with a new mate she took no notice of the egg. This I also expected would be the case; but to my surprise, on Saturday afternoon she laid two more eggs, one full-sized, but with a rough and imperfect shell, it was hard but too thin; the other was about the size of a sparrow's and with a similar or rather worse shell than the third egg. The hen appears somewhat ill, though again mating, so I give her hempseed and Indian corn. I have kept Pigeons for upwards of a quarter of a century, but never had a similar case. The Powters were in a loft by themselves, so I know that no other bird laid any of the eggs. Does Mr. Brent think the hen will be injured, and what would he advise me to do? I first thought of giving her loosening food, but was afraid.

I beg to thank Mr. Brent for his extremely kind and most interesting reply to my question about Fantails. That which he stated about the colour, and also the occasional imperfections seen in the colour of the eyes was quite new to me, and is a valuable hint in natural history. I see that Mr. Brent, like myself, thinks white the original colour of Fantails. I have had a private letter from a great breeder of them, who also thinks the same. I must, however, beg to differ from Mr. Brent, that coloured ones, if good, are, therefore, the more valuable. I incline to the idea that we should keep to the original colour in every variety in order to have the best and purest birds, but, of course, this is a matter of opinion.—WILTSHIRE RECTOR.

**ESSEX POULTRY SHOW.**—This Poultry Show is not a private speculation, but will be held in conjunction with the annual meeting of the Essex Agricultural Association, and the prizes paid by the local committee, which includes nearly all the gentlemen of the district. In fact, the secretaries guarantee the due payment of every prize.

#### HIVES WITH ENTRANCES AT THE TOP.

HAVING worked my bees on the depriving system for the last twenty-five years I have made my own hives, and have always constructed them so that the bees may enter at the top. The advantages of this are, in my opinion, very great. In the first place it thoroughly ventilates the stock, and supplies them with a constant current of fresh air (which our sanitary commissioners tell us is very requisite if we wish to enjoy perfect health) in the easiest possible manner, as the cold air always sinks to the bottom, while that which

has been used for respiration, and is consequently impure and damp, rises to the surface, and finds easy egress. Since I have adopted this method I have never lost a hive, nor I may say a single bee, through mildew, which I think is something to boast of. Another advantage is, that the bees have not so far to carry their honey, as they invariably place it at the top of the combs, and it is more easy to descend than to ascend with a load. Again, when a swarm is placed in an empty hive many thousands are employed in forming chains for the workers to ascend and construct the combs; and, although my plan does not entirely do away with the chains, I have always observed that a much greater number of bees were spared for collecting than when they have a bottom entrance, and I have consequently been able to put on my supers two or three days earlier.

I have never in my life seen or read of this plan, but I have read about inverting the old bell-shaped hives containing stocks to allow of supers being put on, and it was this that first suggested the idea to me; but I have a great objection to this plan, as it gives the bees a great deal more trouble to clean the hives, and it does away with the means of helping them, as the combs are then fast to the bottom instead of the top, and in course of time become clogged up with that dust and dirt which is always found on the bottom board, and which it is very necessary should be removed.—C. WILLIAMS, *Kingsland, Shrewsbury.*

[You appear to have originated and successfully carried out an idea which occurred to us, and was entertained with much enthusiasm some four or five-and-twenty years ago. In our own case, however, it never went farther than a sketch upon paper, and was ultimately abandoned without being reduced to practice, on account of the difficulty which we believed the bees would find in removing their dead and cleaning out their hive through an entrance at the top, as well as the excessive tendency to breed in supers which we imagined would be developed under such circumstances. We should be glad of a sketch and working description of your hive.]

#### UNITING BEES.

I HAVE two stocks of bees standing side by side which I should be glad to unite, if such a course is practicable at this season, the one in a common the other in a flat-topped straw hive. This latter is a weak stock. Might I place the common hive over it, having previously closed the apertures in its top with perforated zinc, and after leaving the two hives in this position for about twelve hours remove the zinc and allow the bees to unite?—H. T.

[We believe the safest mode of uniting your two stocks would be by inverting the weak one in a pail, and standing the other upon it. Then blow a little smoke into the interior, secure the bees by winding a long cloth round the junction of the two hives, and rap the lower hive until its inhabitants ascend into and unite with the bees of the upper one.]

#### VERY WEAK HIVES IN SPRING.

YOUR much-esteemed correspondent Mr. S. Bevan Fox in his very interesting report, "My Apiary in 1864," most clearly establishes the advantages of joining weak hives in spring. With his remarks I most heartily concur. Still hives are sometimes to be met with so very weak at this season (possibly casts or virgins of the preceding year), and the surviving working population so very scant, as to make a scarcely perceptible addition to the colony into which they are merged, while their valuable young queen is consequently sacrificed by such a procedure.

In extreme cases of this nature a still better plan may be successfully adopted. Administer what small quantity of food is necessary to preserve the little band in life till the advent of the swarming season, drive them as soon as a swarm comes off, and capture their queen, then introduce her to the stock whence the emigrants proceeded. The effect will be that breeding will thus go on uninterruptedly, and two prime swarms to all intents and purposes, if I may use the expression, be looked for from one stock the same season. The first swarm, if not otherwise destined, might with effect occupy the works of the driven weak hive.

The foregoing operation may best be illustrated by a case from my own apiary. In the spring of 1863, acting on the best advice your excellent contributor "A DEVONSHIRE BEE-KEEPER" could then offer me, I in vain attempted to strengthen the foul-breeding stock sent me by exchanging frames with my strong black colonies, thereby carrying contagion into my whole apiary, save one "beat-out" of the preceding fall in a Stewarton-hive, which fortunately escaped contamination, being considered too weak at the time to aid in the work. Finding this hive subsequently my only hope, I very carefully nursed it, so that by the beginning of June it was quite full. I then drove an artificial swarm, and having placed it in one of the many pure-combed frame-hives I had prepared for Ligurian propagation, sent it to a distance.

In one of the diseased black colonies was a very fertile favourite queen, which I was very loth to destroy; her formerly numerous progeny had by this time dwindled to the zero point, I therefore destroyed them, and by way of experiment set her over the "beat-out," and the following day introduced her to her new subjects, who, I was gratified to find, welcomed her most cordially, and I saw her no more till, about three weeks thereafter, she most unexpectedly proudly emerged at the head of a very fine natural swarm, which, also was hived in a combed-box. Shortly after the artificial swarm sent forth a good virgin, which was similarly disposed of; and the "beat-out" at the usual time gave a second, or strictly a third, swarm, hived in the same manner.

By the 1st of August, when a second Ligurian stock arrived from Devonshire, it was a positive relief, so full were they, to make from each of the two strongest of my stocks artificial swarms, to be Ligurianised. By a little management my poor little, exclusively-sugar-fed, "beat-out," was thus multiplied into seven first-rate colonies, amply formed to stand over the winter had all gone well; but most unfortunately, as the readers of THE JOURNAL OF HORTICULTURE have been already apprised, the second Ligurian colony brought with it again the desolating plague, so that the spring of 1864 found me beginning the world once again with a single sugar-fed "beat-out," the gift of a friend.—A RENFREWSHIRE BEE-KEEPER.

#### SWARMING VERSUS STORIFYING.

NOTICING a discussion in your valuable Journal under the above heading, I now make a first attempt at describing my bee experience, in the hope that it may prove interesting enough to obtain a place in your columns. A few years ago I took a great fancy to possess a hive of bees, more for the pleasure I anticipated in studying those interesting insects than for any benefit likely to result from their possession. I was then entirely ignorant of all that pertained to bees and bee-keeping, and my locality being considered unsuitable for the pursuit, my friends endeavoured to dissuade me from the attempt. I may mention that I reside in the western suburb of Greenock, in the vicinity of several of its celebrated sugar refineries, happily styled by you some time ago, "slaughter-houses for bees." From the scant pasturage of a town neighbourhood I was afraid they might be tempted thither, or possibly across the Firth of Clyde to the opposite heathery hills of Argyllshire, in too many cases never to return.

Nothing daunted, however, I procured a prime swarm, and set them up in my garden, which unfortunately slopes to the north. I became deeply interested in my industrious little favourites, and watched with much pleasure during my leisure hours their many movements, from the advent of the first load of pollen in the spring to the expulsion of the last lazy drone in autumn. Although I reaped no honey harvest I most carefully fed my bees, as their necessities seemed to require, and by-and-by purchased a weighty straw skep as an addition to my stock. However, the summer of 1863 found me where I started—with only one stock, although I never destroyed any of them, and only on one occasion obtained a little honey. The chief cause of my want of success I ascribed to my stocks being weakened in population from swarming, their reduced numbers being barely adequate to gather what would sustain them. But what came of the swarms? you may naturally ask. These generally came off in my absence during business hours; and invariably, even though hived, made off to people the

combs of defunct colonies in the gardens of some of my neighbours, whose hives swarmed abundantly, but who took no pains to feed, allowing them to perish and be thus re-peopled.

As mentioned, I had but one hive in the summer of 1863, and having the good fortune to know your esteemed correspondent, "A RENFREWSHIRE BEE-KEEPER," I made him acquainted with all my misfortunes. He strongly advised me to order a set of improved Stewarton octagon hives, and keep my bees on the depriving or storifying plan, as being by far the most suitable in my case. I was to drive the bees of the old stock into one of the boxes, appropriate its contents, nadir with breeding-box after breeding-box as the inmates required room, and not to look for any honey that year. From the greater earliness of the swarms in mine compared with my friend's inland and later locality, he raised my hopes by telling me, that notwithstanding my bad start, I might yet turn out a most successful bee-keeper. I received the octagon boxes, the bars all moveable, with the neat little Woodbury rib, to which, as directed, my bees were speedily transferred and rapidly made combs, at the end of the season becoming a weighty stock. In the beginning of summer this stock was about full in all the boxes, and I much dreaded the escape of a swarm, when I fortunately met your correspondent one day in town. He explained that to obviate this and again to stimulate their exertions, I could with effect re-arrange the boxes, appropriate end combs, excise royal cells if any, and admit to a super. This operation of taking the boxes apart and having the immense population of this strong colony about my ears, I frankly owned my want of nerve to carry out, but he quite relieved my fears by kindly promising to send his man to assist me in the work, which he accordingly did. We got through most capitally, and I was put in possession of 14 lbs. of beautiful honey. I had the further satisfaction of seeing my bees go on with redoubled ardour, and the super occupied. As I saw it verging towards completion, I put on a second above the first (my friend having warned me of the risk of placing an empty box between a full one and the stock). This too was taken possession of and the first removed so soon as completed, and in like manner a third was given when the second was well advanced, which latter was afterwards taken off complete. The weather broke before the third was altogether filled. However, on the whole, I was highly pleased with the result, this one storified stock having yielded me 68 lbs. nett, of the finest honeycomb entirely free from either pollen or brood. It was my intention to have given the weight of the stock as it now stands, but on trying to raise the pile of boxes out from their octagon cover, I found it such a lift that I thought it prudent to leave it alone in the meantime. The great weight, however, augurs well for a repetition of the preliminary spoliation process early next summer, which I think a much safer procedure than encroaching on the store in the breeding portion of hives in autumn.

My experience of the storifying process in the past season has been so satisfactory that I have already prepared two handsome octagon covers to set up as uniform with the first, to people which it is my intention to purchase two good colonies in common straw hives, transferring by means of frames, which I think of adopting, their entire contents, combs as well as bees, into the two new sets of octagon boxes, thereby avoiding the risk of swarming, and I hope to be able to report the success of my fresh attempt in the coming season.—AMATEUR.

#### STORE-ROOM FOR BACON.

WHICH of the three following positions would be the best for keeping six sides of bacon? I have an underground room, with a window opening to the garden, with a door opening into a passage, which passage has a door leading to the garden also. I could cut a ventilator through the top of this door so as to let a current of air through the room.

I have some spare room in the scullery attached to the kitchen; would this be a suitable place?—this is also underground—or would the steam from washing, &c., affect it? I have also a spare room at the top of the house, which I could devote to the purpose. Perhaps "A WILTSHIRE RECTOR" could give me some advice.—A HOUSEHOLDER.

["A HOUSEHOLDER," like the late Sir Robert Peel, offers

three courses for choice, but I cannot wholly approve of any of the three. The second is without doubt much the worst, the steam would be ruinous, and the room being underground, far from favourable. The first is better, but still underground. I should, therefore, advise "A HOUSEHOLDER" to try the room at the top of the house, especially as we have not winter before us. Let the bacon be well watched, I mean frequently examined, lest the fly should get into it; neither let it be covered up, for then detection is less easy.—WILTSHIRE RECTOR.]

#### OUR LETTER BOX.

EGGS EXPOSED TO FROST (G. H.).—There is no doubt eggs are injured by frost. We are unable to give you the number of degrees, but we have proved, to our cost, that there are frosts in May hard enough to spoil them. Our impression is that 6° will do it. The appearance of a frozen egg is that of one with the yolk and white partially mixed, and giving the latter a cloudy appearance. The difference, though not to the same extent, is much the same as in oil in warm or frosty weather.

DORKING COCK SUBSTITUTED FOR COCHIN COCK (W. M.).—The substitution of the Dorking cock would, in our opinion, increase the size and lighten the colour of the eggs. Your next is a vexed question. Some will tell you the former influence will not cease till all the present laying of eggs has taken place; others will tell you the new breed begins a fortnight after the change. We are disposed to hold with the former opinion. Those who differ are as well versed as ourselves. Observe your birds narrowly, and act as judge between us. The Bantams may run with the large variety.

M. DE SORA (H. S.).—We shall be very much obliged if you will give us your experience more in detail. We also believe Mr. de Sora to be the "poultry Mrs. Harris." We have sought him all over France, but without success.

DUCK'S LEGS PARALYSED (Rouen).—There are places where the water is not favourable for Ducks, and we knew one where every Duck that was put on the pond was immediately cramped, and finally paralysed. The water was remarkably clear and cold. This is, however, a rare case, and where such are frequent we are always disposed to look for want of constitution or improper and insufficient feeding. Put the Ducks for a time in an outhouse, or a pen of some kind, cover the floor with straw, and feed on oats put in a trough, with plenty of gravel. Another cause of such attacks is, that ponds are very often made receptacles for everything, and that poisonous matter gets in. Snow water disagrees with Ducks, and they have had a great deal of it this winter.

PRODUCERS OF LARGE EGGS (Idem).—If you do not like Spanish, the Crève Cœur, and La Flèche are equally good layers, and do not sit. We are not sure they bear close confinement so well as the first. Their eggs are, if anything, larger. All hens have laid badly this year.

CONFINING GESE (A. W.).—We never shut up our Geese, yet they always lay their eggs in the house.

FLOOR OF PHEASANTRY (A. B. C.).—The floor of a Pheasant-house should, like that of a fowl-house, be of earth, and if covered with loose fine gravel, so much the better. You may put a small box in one corner if you please, but both Golden and Silver prefer to scratch out a hollow and to lay there.

SICK PIGEON (H. L. C. B.).—I think you cannot do better than give your hen Barb, which has a rattling in her throat and watery eyes, a pill containing one grain of calomel, to be repeated in a day or two if required, and a bolus of cod liver oil made up with flour or meal, twice a-day.—E. P. B.

LARK WITH WRAKENED SONG (F. B.).—Your Lark, whose voice has become weak, seems either to have caught cold, or the hempsed has disagreed with him, probably from being too fattening. Alter his food, give him no hempsed, but cooked meat and hard-boiled egg instead, and put some Spanish liquorice in his water. When recovered feed on minced cheese and oat groats. Let him have a fresh turf as often as convenient.—B. P. B.

COLOUR OF A BEE-HOUSE (A. B. C., Hurstpierpoint).—We deem a light stone colour the best, as tending to keep the house cool in summer. Alighting boards should be left unpainted, but it would be well to shelter each by a porch, and paint these porches and their interiors of different colours for the better guidance of the bees.

VARIOUS APIARIAN QUERIES (W. B. W., Stone).—Buy "Bee-keeping for the Many," price 4s. (free by post from this office, 5s.). Let your stocks swarm, and stock Stewarton hives with the swarms. These hives are likely to answer your purpose as well as any, but none can be absolutely relied on to prevent swarming in all seasons. Snowdrops and crocuses in the spring, borage and mignonette for the later months.

BEES ON A HOUSE ROOF (A. A. Y.).—If sheltered as you describe, bees are likely to do better on the roof of your outhouse, than in a confined courtyard. Buckwheat forms excellent pasturage for bees, and a few acres of it would be of great advantage. It should be sown in April.

TRANSFERRING BEES (Beginner).—This is rather too difficult an operation for a beginner, but full instructions for transferring bees from a common hive to a frame-hive were given in No. 75, of our New Series. Drones are much larger than workers, and may usually be seen on the wing in great numbers during the middle of a fine day in May, June, or July. The queen is seldom seen by ordinary bee-keepers. She is about one-third larger than a worker, but is less bulky, and has a longer and more pointed abdomen than the drone.

PUTTING SUPERS ON COMMON HIVES (Jersey).—Get a square platform, made of three-quarter-inch wood, of sufficient size to accommodate a full-sized super, and clamped to prevent warping. Cut a three-inch hole in the centre, and insert three or four wood screws an inch long in the underneath side, leaving their heads projecting about half an inch. Then bed this platform in mortar tempered with cowdung on the top of the hive, and when the mortar is set cut an aperture in the straw with a sharp pen-knife, corresponding with that already existing in the wooden platform. This will enable you to super such of your hives as you may deem most suitable, upon which point, however, you must form your own opinion.

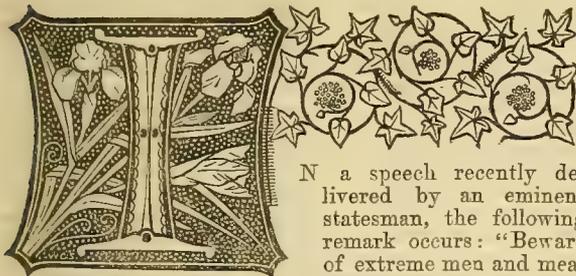

SHEEP-FEED (W. Buckell).—Your best chance of obtaining a customer is by advertising what you have to sell. —

WEEKLY CALENDAR.

Day of M <sup>th</sup>	Day of Week.	APRIL 11-17, 1865.	Average Temperature near London.			Rain in last 48 years.	Sun Rises.		Sun Sets.		Moon Rises.		Moon Sets.		Moon's Age.	Clock before Sun.	Day of Year.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 57.7°, and its night temperature 36.0°. The greatest heat was 73° on the 14th, 1852; and the lowest cold, 20°, on the 14th, 1847; and 15th, 1852. The greatest fall of rain was 0.63 inch.

ORCHIDS IN COOL HOUSES.

**N**a speech recently delivered by an eminent statesman, the following remark occurs: "Beware of extreme men and measures, they are not trust-

worthy; as a rule you will find the men with sound judgments taking the middle course." This excellent advice appears to me to have a very wide application: for instance, if an advocate of the "cool system" of growing Orchids were to advise a temperature of say 40°, and another person opposed to greenhouse treatment were to recommend 80° as a condition to secure success, the probability is that 60° would be the safe course.

It appears to me that the tendency in Orchid cultivation at the present time, is to go to an extreme. This "cool treatment" about which we hear so much, is, in my humble opinion, a dangerous experiment. I have tried it on the following Orchids, some of which may be termed representative plants, and in my case it has failed—*Dendrobium speciosum*, *D. nobile*, *D. fimbriatum*, *D. Paxtoni*, *Odontoglossum grande*, *O. citrosum*, *Oncidium altissimum*, *Brassia maculata*, *Trichopilia tortilis*; and *Lælia anceps*. They have been subjected to a temperature of from 45° to 50° during the last eighteen months, and their condition is worse now than when I commenced the trial. On the other hand, plants of the same kinds as those which I have named, have been grown in the Orchid-house, ranging from 60° to 70°, and these are in excellent condition.

That many good plants have been lost in consequence of too much heat having been given, I know, more especially some of the most lovely of the rare *Odontoglossums*. These, I am certain, together with *Lycaste Skinneri*, and a few others that might be named, will grow much better in a cool house, but when I see long lists of valuable Orchids recommended to be grown in a greenhouse, I confess it somewhat staggers me, as it is quite opposed to my experience and observation. My own impression is, that the number of Orchids that will grow in a greenhouse is extremely limited, and I fear that many persons who are now endeavouring to cultivate such plants as *Cattleya Mossiae*, *Lælia purpurata*, and *Odontoglossum citrosum*, in cool houses, will at no very distant day feel strongly inclined to treat their advisers coolly.

It is said by the advocates of the "cool system" in support of their theory, that in their native habitats ice is often found on Orchids that we grow in this country in a hot Orchid-house. Of this fact there is no doubt, but I have yet to learn that an exact imitation of the

natural conditions by which plants are surrounded, is the most successful mode of growing them artificially. It is a well-known and remarkable fact, that many of our native plants, Ferns especially, thrive best when subjected to the temperature of our stoves and greenhouses. I should be delighted to find that the many Orchids recommended for greenhouse treatment flourished in their cool quarters; it would be much more comfortable and economical, consequently would induce many more to grow these beautiful objects. The experience of all acquainted with the subject will be invaluable, and if our object be to edify one another, we shall derive benefit from the discussion of this important subject.—BRUCE FINDLAY, *Manchester*.

ON FORM AND COLOUR.

SOME months ago in a communication entitled "A Plea for a Compromise," I ventured to proffer a few remarks on form and colour, especially with regard to the arrangement of plants in flower gardens. The subject, I am aware, demands the efforts of a much abler pen than mine; but, if I mistake not, the contributions to THE JOURNAL OF HORTICULTURE are taken by your intelligent readers for what they are worth. My purpose is to show with regard to modern flower gardening, that at least one important element of pleasure which exists in nature in endless and exquisite profusion, is entirely ignored, while at the same time the fundamental principles of harmony in colours are constantly violated.

I do not wish to commence here an indiscriminate attack upon the system of massing colours in large gardens. Its most earnest advocates, however, must admit that it is a system open to grave objections, and fraught with danger to the true interests of horticulture. Of late years the end and aim of popular gardening has been to arrest the eye by violent and unnatural contrasts, effected by masses and continuous lines of positive colour. The result has been, too often, no harmony, no repose; the eye pained and wearied with the contemplation turns instinctively to the blue sky or fresh green turf.

A blind man was asked what was his idea of scarlet. His reply was curiously suggestive. "It is like the blast of a trumpet." Colour has its characteristics, its harmonies and discords, its fortes and pianissimos, its light and shade. The "tantarra" of the horn with its sustained and piercing monotone—its streaks of sound, if I may so express it, pleases us chiefly from its agreeable associations—the village postman, the mail coach, and the cover side—elsewhere it is simply unendurable. A single band or mass of intense scarlet—say Tom Thumb Geranium, is the blast of a trumpet. As we look from the window it assails us; if we enter the garden it impinges on the retina of the eye like the trumpet blast on the ear, it glares at us through the hot noon of the dog days, and if we gaze on it for a moment, by a well-known optical illusion the impression remains for a time on the eye, and everything is spotted with scarlet. Now edge this belt with yellow *Calceolaria*—say *Aurea floribunda*

(a very common arrangement in what are called show gardens), and we add another monotone, which I will compare to the scream of the clarinet. Imagine, then, reader with the sensitive nerve, if you can without a shudder, the utterance of such a diabolical yell. The nearest approach in nature to the scarlet of Tom Thumb that I can think of, is the common Corn Poppy; but what more beautiful than the little "headacher" glinting and glowing among the stalks of the browning Barley with a rich undergrowth of Clover and seeds? The Poppy leaf, however, is stained with purple at its base, and is crumpled in texture like the wing of a newborn butterfly. The mass, too, is dispersed and broken by the Barley stalks mingled with the blue and white Cornflower, and blended, except in a direct line with the eye, into a purplish rosy bloom.

Colour in nature is seldom, if ever, positive. Gaze around you in a landscape, there is not a square inch of positive colour. In a flower there is a subtle gradation of tint from the tip to the base of the petal. In double flowers, especially, the shadows of overlying petals and effects of transmitted light are very considerable. It is these, added to the charming irregularity of the petals, which give to the Rose its exquisite grace. In some single flowers—the white Lily for example—the depth of the convolutions renders the effects of the shadows and transmitted light still more characteristic. Now one result of what is called successful hybridisation has been to render colour more positive. Indeed the aim of the hybridiser seems to have been to obtain flowers of positive colour: this applies more particularly to bedding Geraniums; we have as a result colours of the Tom Thumb and Frogmore class which may be called "the hard scarlet section," they are a necessary consequence of the present system of massing colours, when the garden is appreciated chiefly from the drawing-room window or from the balcony of a Crystal Palace.

One remarkable characteristic of plant-nature is the preponderance of green foliage; the flower is the gem, the foliage the massive and beautiful setting. In the parterre the turf serves this latter purpose to a very imperfect degree. However pleasing in some respects the fresh green turf, it is ill adapted to furnish the light and shade, the varying green tints of growing shoots, and the rich luxuriance of leaf-growth, necessary for a perfect *coup d'œil*. It is the intermingling of leaf and flower that gives to the flower-bed its most charming and interesting feature—the infinite play of light and shade caused by the varying height of flowers and leaves. Foliage, then, should not only be present in abundance, but the form and distinctive character of the foliage should be conspicuous, and this principle should obtain not only in the planting of flower-beds but in the exhibition of specimen plants and cut flowers. The beauty of great masses of bloom in the Azaleas and Geraniums exhibited would be enhanced by the presence of a more adequate proportion of healthy green foliage. Cut flowers, too, especially Roses (and here I join issue with your able coadjutor "D.," of Deal), would surely present a more pleasing aspect if accompanied by a spray of their own foliage, which is, moreover, in many instances, as characteristic as the flowers themselves—take, for example, Eugène Appert, Lord Raglan, and Gloire de Dijon. There is something incongruous, it appears to me, in these long-extended lines of decapitated Roses destitute of a single green leaf. I remember still the indignant feeling that filled my breast years ago when a boy—an old lady being solicited for a Rose, broke off an opening bud, and stripped it, kind soul, of every vestige of foliage.

Speaking of Roses, what ugly inartistic objects are standard Rose trees! towering above our children's heads, dotted about on their solitary spindle shanks. On their first introduction novelty and its accompanying price caused them to be much sought after. A noted Rose-grower has suggested pyramidal trees; but what more simple, and beautiful, and eligible than a well-trained bush? To be sure, they are only a quarter of the price, but when on their own roots it is well known that they produce much finer flowers. If standard Roses must be grown, let them grow naturally, so as to shield the hideous stem; the flowers may not be quite so fine, but they are much more numerous, and a standard 4 feet high with its branches forming a beautiful dome of foliage and flowers is a far more beautiful object than the

things now grown as standards. Last year I had a plant of Coupe d'Hébé so grown without the aid of the pruning-knife. There were at one time upwards of one hundred fully-expanded blooms decking its branches, which drooped in graceful wreaths to the ground. By the way, what Rose, excepting the old Cabbage, of course, is more beautiful than Coupe d'Hébé? Not Comtesse de Chabillant, certainly, in spite of the catalogues. It is too like a florist's flower.—T. W., Harrow.

(To be continued.)

## GENERAL HORTICULTURAL EXHIBITION AT AMSTERDAM.

Our earliest ideas connected with gardening associated with Holland; and when we were informed that the Royal Netherlands Horticultural Society were making an effort, under the patronage of their Queen and the Prince of Orange, to assemble the botanists and gardeners of Europe, and to have at the same time an exhibition of plants, flowers, and fruits, and of the art productions relative to gardening, we hailed it as a right effort and in the right place—but let no one suppose that such an effort is needed to revive there a love of horticulture. The love of bulbous flowers is still there in the ascendant, as we shall hereafter particularise; but more than that, a general love of gardening prevails. It is gardening under difficulties, for the climate and excess of water, both in the soil and atmosphere are at a maximum, yet first-rate gardening prevails. The growers of plants for sale are among the princes of florists and nurserymen; and even down to that class who live in barges throughout the year, their cabins are to be found adorned with flowers, and Tulips, Crocuses, Hyacinths, and Anemones are grown by them in pots placed in secure corners about the barge.

Well, to Amsterdam, on the 5th of this current April, were invited 150 of the botanists and gardeners of the Netherlands, 56 of France, 75 of Belgium, 1 of Switzerland, 2 of Italy, 1 of Spain, 27 of Prussia, 7 of Austria, 3 of Bavaria, 3 of Hanover, 3 of Wurtemberg, 3 of Baden, 2 of Saxe, 2 of Luxembourg, 1 of Weimar, 6 of the Grand Duchy of Hesse, 1 of the Electorate of Hesse, 2 of Nassau, 5 of Hamburg, 1 of Frankfurt, 1 of Sweden and Norway, 2 of Denmark, 4 of Russia, 1 of Schleswig, and 12 of Great Britain. Of these, very few failed to attend, and, consequently, at noon on the day we have named, were assembled in the Palace of Industry nearly 300 of the most distinguished botanists and gardeners of Europe. It would be invidious to particularise even one, but whoever had the pleasure of being there saw assembled, we hope not for the last time, some of the best botanists and horticulturists of nearly every State in Europe.

The President of the Royal Horticultural Society having addressed this assembly, they were divided into ten sections. To each section a certain number of the classes of plants and relative articles exhibited were assigned, and to which they were to award prizes. This was no easy task, and again and again had a show of hands to be taken before a decision could be obtained.

The Palace of Industry, in which the exhibition was held, was erected in 1863 for an international exhibition of the same kind, but on a smaller scale as that in this country at Kensington; but the Netherlands, with sounder judgment than usually prevails in such matters with us, erected a building so ornamental and so durable as to be worth preserving for similar purposes in after-years. The best idea we can give of it is by describing it as two conservatories like that in the Royal Horticultural Society's Gardens at Kensington, but more ornamented, with a gallery all round instead of only on one side, and with a handsome centre, surmounted by a lofty dome. Besides the centre nave, if we may so describe it, there are side aisles, and over these are rooms, suitable for the supply of refreshments, committee meetings, and similar purposes.

The floor of the nave was marked out by broad turf edgings, so as to represent a geometrical garden. In the beds thus bordered were the plants exhibited, grouped and arranged, and the paths among them were devoted to the spectators. There is a fountain in the centre of each half of the nave, but these rather marred the effect, for they are neither artistic nor powerful.

Our readers would take little interest in a detail of the names of the prizetakers, so that we shall name but few of them, and be more particular about the plants. We will pass over the general collections, because generally inferior to those we see at our chief London exhibitions. The Azaleas were small specimens, but well bloomed, and to our taste spoiled by being grown as a semi-globular bunch, on the top of a long naked stem. The Roses were excellently bloomed, but similarly offensive by being cultivated, though in pots, on long, naked, four-foot stems. The Camellias were most excellent, and a new white one is about the largest, best-shaped, stout-petaled variety we ever saw.

#### NEW PLANTS.

Before we describe the plants exhibited, we must add our protest, to that of many others, at the erroneous awards made of many of the prizes, and we must say that they must not in any way be taken as a criterion of the merits of the various plants exhibited.

For the prizes for twelve new plants introduced by the exhibitor there were four exhibitors—viz., Messrs. Linden, of Brussels; Veitch, of Chelsea; Amroise Verschaffelt, of Ghent; and Groenewegen, of Amsterdam.

Mr. Linden's collection was composed of an *Anthurium magnificum*, very similar to, if not identical with, the *Anthurium cordifolium* sent out recently by the Royal Horticultural Society; an *Echites* much in the way of nutans. *Franciscea Lindeniana* in bloom, resembling *confertiflora*; two *Urospathas*, named *marmorea* and *maculata*, with leaves something similar to *Caladium cupreum*, but not quite sufficiently developed to decide as to their merits. There were also *Marantas*. One named *rosea picta*, with small round leaves, nicely marked with red, seemed to us one of his most promising plants. He had also *Reimijia candida*, a plant with jasmine-like flowers, but not being open we could not speak as to its merits. Undoubtedly the best plant in the collection is *Aralia mids-de variegata*, from Japan, resembling more a splendid silver tree-ivy than any other plant. The leaves are about two inches in diameter, of great substance, and beautifully variegated.

Mr. Veitch showed his fine *Maranta Veitchi*, a beautiful new *Sonerila*, with leaves about three inches long and spotted with large pink spots; *Urceolina aurea*, a fine bulbous plant, with yellow flowers, *Polystichum* species, *Lycopodium* species, *Schismatoglottis* species, and others.

Mr. A. Verschaffelt showed in his collection a splendid Fern, named *Cibotium regale*. This is a greenhouse kind, and its fine fronds, which measure eight or nine feet in length, were much admired. This variety forms a stem of five or six feet high, when the fronds are proportionately large. He had also a new stove Palm, named *Verschaffeltia splendida* by Mr. Wendland, of Hanover, (being a new genus), which was also much admired; but it will evidently require a large house, being a strong grower. We noticed also in the collection two new kinds of *Amaranthus*, with leaves of the colour of *Amaranthus melancholicus ruber*, but very much smaller. The plants are apparently very easily cultivated, but we do not think they will ever be very useful for decoration. There was also a curious *Dracæna*, a seedling, having evidently the same character as *Dracæna indivisa*, but the foliage was of a bright bronzy hue and had a very nice effect. The collection was made up with two variegated *Smilaxes*, a *Dieffenbachia gigantea*, with the stem spotted like *D. grandis*, but having also the leaves spotted with white; a *Marattia jacarandafolia*, *Maranta splendida*, &c., but not calling for any particular notice.

Mr. Groenewegen's plants were much smaller, and some not quite fully developed, and except a variegated *Saccharum officinarum*, from Japan, which has the leaves more or less striped with white, this collection did not contain anything of very striking merit.

For plants introduced before 1864 Mr. Linden and Mr. A. Verschaffelt again competed, and also Mr. J. Verschaffelt, of Ghent. The former had in duplicate nearly all the plants already named in the first section, and also a variety of *Dendrobium nobile*, with flowers of a pure white ground; *Coccoeypselum metallicum*, a trailing plant, having the leaves completely bronzed; *Alocasia singaporense*, a strong form of *Caladium Veitchii*; *Saurauja sarapignensis*, a plant with large red leaves, which will probably make a fine out-

door decorative plant, being similar in habit to *Wigandia caracasana*; *Spharogyne cinnamomea*, *Cissus amazonicus*, *Crescentia Liboniana*—the three latter of which we have seen in London before. Mr. Verschaffelt had plants of *Agave Schidigera* var. *ignescens*, a fine-looking variety; *Japanese variegated Camellia*, *Dracæna Cooperi*, a variegated *Conoclinium*, *Prumnopytis elegans*, &c.

Mr. A. Verschaffelt had many of the plants similar to those described before, and also *Aralia Sieboldi reticulata*; several fine Japanese *Acers*, including *sanguineum*, which is in the way of *japonicum polymorphum* and *Frederici Guiliemi*, with variegated foliage; *Agave hystrix*, from California; a variegated *Ardisia* from Japan; *Achyranthes Verschaffeltii*, &c.

For six new plants introduced by the exhibitor there were two collections of plants from Mr. Groenewegen, comprising *Phyllogathis rotundifolius*, *Jambosa* species, *Aglaonema oblongifolium*, *Symphonium divaricatum*, a form of *Caladium Veitchii*, *Cycas pandanifolia*, *Medinilla farinosa*, *Nephelaphyllum tenuifolium*, much in the way of *N. pulchrum*, but with smaller and more deeply coloured leaves. The other plants do not require any particular notice.

In the section for three new plants, there were no prizes awarded, the only plants shown being three *Begonias*, with reddish crimson foliage and white flowers, but which are certainly not at present to be looked on as any improvement to already well-known kinds.

In the section for one new plant in flower, introduced by the exhibitor, there were seven plants offered for competition. Three came from Mr. Veitch, of Chelsea; *Franciscea Lindeniana* from Mr. Linden; *Siphocampylus* species, we believe from Leyden Botanic Gardens; *Tillandsia thyrsoides* from Utrecht; and the new *Abutilon* from Mr. A. Verschaffelt. It is quite certain that in this instance the prize was given to the worst plant of all—viz., the *Tillandsia*, which, we believe, is a very old plant, and, besides, is ornamental neither in flower nor foliage.

Mr. Veitch's three plants were his two new seedling *Rhododendrons*, named respectively *Princess Alexandra* and *Princess Helena*, and another unnamed kind; and how the jury could have overlooked these and the other much finer plants than the *Tillandsia* is incomprehensible. The second prize was given to the *Abutilon* of Mr. A. Verschaffelt.

In the section for a new plant not in flower, and not yet for sale, there were nine competitors; and here again we must totally disagree with the awards made. The first prize was given to a plant from the Leyden Botanic Gardens—*Cyrtandra bicolor*, a Gesneraceous-looking plant, with leaves about 5 inches long, and of a glossy bronzy hue, but certainly as a plant remarkable for its beauty of foliage not to be compared with others in this class. Mr. Veitch came second with *Maranta Veitchi*; and the other plants exhibited were *Aralia Sieboldi foliis reticulatis* from Mr. A. Verschaffelt, a fine plant from Japan; *Yucca aloifolia filamentosa*, a new variety imported last year from South America by Mr. J. Verschaffelt, who also exhibited *Agave Schiderea ignescens* in this class; *Rhopala nobilis* from Mr. Linden; and *Chamaerops humilis foliis aureo-variegatis* from Mr. Vervaene, of Ghent. This is a seedling raised two years since, and the leaves are slightly striped with bright yellow markings, which are, however, at present hardly sufficiently developed to enable one to judge fully as to the merits of the plant.

In the class for collection of bulbous and tuberous plants in bloom, Tulips and Crocuses excepted, we observed some fine *Fritillarias*, *Iris herbacea pumila violacea*, a dwarf variety of the colour of the Neapolitan Violet; also *Iris reticulata*, *Sprekelia formosissima*, *Lilium auratum*, *Lilium Feu Korman*, and many other plants not particularly interesting, a good specimen of *Imantophyllum miniatum*, and some nice dwarf *Amaryllis*.

In the class for collections of twenty-five *Amaryllis* for nurserymen were some of the finest varieties we have ever seen, particularly *Fidelio*, *Johanna Catharina*, and *Jean Paul*.

In the classes containing the *Hyacinths* in pots there were many good specimens; but they were by no means so fine as those exhibited in London by Messrs. W. Cutbush and Son, and Mr. W. Paul. The sorts were the same as we usually receive from Holland.

For the best new single *Hyacinth* not yet in commerce.

the first prize was given to a good black variety, and the second prize to a very inferior blue one.

The first prize for the best new double Hyacinth was awarded to No. 295, a dirty white variety, so utterly wretched, that how the Jury could possibly have awarded it we are at a loss to understand. The second prize went to No. 66, a semi-double red, of good colour, but also a very poor flower.

We were much disappointed with the Hyacinths shown in these two classes, as there were none worth introducing into England.

In the class for collections of 100 pots of Single Tulips, seventy-five varieties, three plants in a pot, the first and second prizes were given by lot to the two collections, as they were considered by the Jury of equal merit; but we considered that exhibited by Messrs. Byvoet as decidedly the best. The sorts were very good, but they were none bloomed so fine as we see them at the shows in England. Proserpine, Roi Pepin, Vermilion Brilliant, Cottage Maid, Keizerkroon, Grootmeester van Maltha, Standard Royal, Rose Gris de lin, Geele Prins, Globe de Rigaut, and Beauté Frappante were amongst those that struck us as being the most desirable.

In the class for Late Tulips the plants were well grown, considering the great difficulty there is in forcing them. The Tulips were planted three bulbs in each pot, and occupied about 60 yards of staging, there being over 4000 bulbs exhibited.

In the class for 200 pots of Crocuses, five plants in each, and at least fifty varieties, there were three fine collections shown, containing many new and fine varieties.

The Hyacinths exhibited in glasses were all well grown, certainly superior to any we have seen grown in England in the same way; and as the Hyacinth requires from five to six years to raise flowering bulbs from seed, and then many years more before a sufficient stock of any sort can be produced for sale, there is little prospect of many new good sorts for some years to come. The growers are now quite alive to the necessity of improving the sorts by hybridisation, but the result of their labours cannot be ascertained for a long time. The Hyacinths were staged from five to six rows deep, and occupied a space of about 80 yards, and the general effect was pleasing, there being altogether about 2000 bulbs exhibited.

We add a list of the Hyacinths bloomed in glasses, to show our readers what can be accomplished in this mode of cultivating them:—La Belle Blancheuse, white; Agnes, pink; Lord Wellington, French white; Parelbod, pale blue; Alba Superbissima, white; Louis Napoleon, crimson; Madame Marmont, white shaded with pale blue; Sir Lytton Bulwer, French white; Van Speyk, pale blue; Emmeline, pale pink; Lord Anson, French white; Rouge éclatante, crimson; Lady Franklin, pale pink; Prince Albert, dark violet; Tubiflora, French white; Cynthia, pale crimson; Heroine, straw colour; Wilhelm de Ersk, pale violet; Mirandoline, white; La Prophète, pale pink, dark centre; Charles Dickens, blue; Von Schiller, dark pink; Grand Lilas, pale lilac; La Tour d'Auvergne, ivory white; General Havelock, dark purple; Conquest, straw; Dame du Lac, pink; Mammoth, white; Prince Albert, dark purple; Garrick, dark blue; Prins van Waterloo, white; La Reine de Jacinthes, rosy crimson; Emma Levray, dark straw; Haydn, dark lilac; Noble par Mérite, pink; Couronne de Celle, pale blue; Solfaterre, pink; Grandeur à Merveille, French white; Grande Vidette; pale porcelain blue; L'Unique, dark lilac; Grande Vidette, white; Amy, rosy pink; Ida, pale straw; Argus, violet, with white centre; Alba Maxima, white; Macaulay, pink; Von Humboldt, darkest purple; Jaune Suprême, straw; and Orondates, pale porcelain blue.

The best of the Hyacinths were—

*Double Reds.*—Noble par Mérite, Susannah Maria, Louis Napoleon, Ornement de la Nature, Lord Wellington.

*Double Blue.*—Van Speyk, Garrick, Laurens Koster, Blocksberg, Comte de St. Priest, Madame Marmont.

*Double White.*—La Tour d'Auvergne, Prins Van Waterloo, La Vestale, Sir Bulwer Lytton.

*Single Reds.*—Macaulay, Von Schiller, Amphion, Mons. Faesch, Le Prophète, Victoria Alexandrina, Solfaterre, Robert Steiger, Cavaignac, Milton, La Dame du Lac, Cosmos, Princess Clothilde, Princess Charlotte.

*Single Blue.*—Grand Lilas, Grande Vidette, Marie, General Havelock, Prince Albert, Charles Dickens, Orondates, Baron Von Tuyll, General Lauriston, Mimosa, La Nuit, Uncle Tom, Argus, Pieneman, Admiral Coligny, Nimrod.

*Single Mauve.*—L'Honneur d'Overeen, Haydn, Psyche, L'Unique.

*Single Yellow.*—Ida, Professor Blume, Koning Van Holland.

*Single White.*—Alba Maxima, Mont Blanc, Grandeur à Merveille, Grande Vidette, Seraphine, Gigantea, Snowball, Queen of Netherlands, Elfrida, Cloche magnifique, Mammoth, Nimrod.

#### ORCHIDS.

M. Linden, of Brussels, sent a well-grown collection of fifteen: this was awarded the first prize, and contained the very rare *Vanda Cathcartii* with five flowers well expanded. It is much to be regretted that this valuable plant should be so very rare. This plant was imported by M. Linden along with *Vanda Gibbertii* from Assam. A good representation of *Vanda Cathcartii* is to be found in Hooker's "Himalayan Plants." This collection also contained *Cypripedium hirsutissimum* with eight flowers, *Ada aurantiaca*, *Brassavola glauca*, five flowers, *Miltonia cuneata*, not so well known as it deserves to be, four varieties of *Vanda tricolor*, two of *Phalænopsis*, &c.

M. Ambroise Verschaffelt, of Ghent, took the first prize for a collection of ten Orchids, comprising, amongst others, the rare *Brassavola Digbyana* finely in bloom, *Cypripedium villosum* and *hirsutissimum*, *Phalænopsis grandiflora*, *Schilleriana*, and *amabilis*, *Dendrobium albo-sanguineum*, a fine strong plant, *Cattleya Trianae*, pale variety.

*Cypripedium villosum*, with sixteen flowers, from M. de Cannart d'Harmale, took the first prize. *Vanda tricolor*, from M. Meulman, second for the best Orchid in flower.

#### FRUITS.

Of Fruits there were several large collections, some of which contained a great variety of sorts, particularly of Apples that are unknown among us. The Apples that appeared to be in the best state of preservation were Court-Pendu-Plat, with which we are all familiar; Court-Pendu-Noir, a variety similar in shape to the former, but entirely of a dark mahogany colour; Reinette Montre, a good solid Apple, that keeps well, and is not unlike our Rymmer, but more ribbed and puckered round the eye, as much so as the Calville Blanche. In the collection of 603 we observed a very handsome variety; it is of the size and shape of the Winter Pearmain, figured in the "British Pomology," and of a very brilliant orange-scarlet colour, with here and there broad broken bands of yellow. Some of the fruit were not so conical as others, and more like the Golden Reinette in shape. It is a fine, solid, and good keeping Apple. The name attached to it was La Bonne. In the same collection, we saw the same variety, under the name of Pomme Corail. Pomme de Châtaigne is also a good keeper, and a handsome conical Apple. There were some good specimens of Calville Blanche in almost all the collections, and in some cases, there were special exhibitions of that variety. Zoete Veen is a small flat Apple, about the size and shape of a Pomme d'Api; but a good deal covered with russet. It keeps well, and is an ornamental little Apple for the dessert; but the flavour is sweet and mawkish. Mère de Ménage we found under the name of Napoleon. A good number indicated an English origin; but it must have been a long time ago, for we have no such sorts now as Engel's Bellefleur. There was a large firm-looking Apple, with every indication of being an excellent sort, either for dessert or kitchen use. It is large, and with angular conical shape, and a great open eye like Blenheim Pippin. It is called Dubbelde Wyker Pippe. We were struck with a handsome medium-sized fruit, an improvement in size on Pearson's Plate, and not unlike it in appearance. The flesh is tender, yellowish, and richly flavoured. It is a fine, dessert Apple, and is now (April 7) perfectly firm and solid, showing no appearance of shrivelling. It is a pretty Apple, and is called Pepperappel. Its shape is short cylindrical, flat on the crown, and with a large closed eye. This was exhibited by 116. In the Reinette de Montbron we recognised our Cockle Pippin, of which the specimen was very good. Adams' Pearmain were also excellent. There were some splendid dishes of Golden

Pippin, as fresh and golden as ever they could have been in the days of John Evelyn, and looking defiance at Mr. T. A. Knight's theory of degeneration. In *Rambour Rouge* we recognised Norfolk Beeding. *Zoete Winter Pipling* is of the size and shape of *Court-Pendu-Plat*, but green, and with an orange cheek; the flesh is tender and sweet, with somewhat of the Newtown Pippin character about it; this we observed in the collection of H. J. de Greeve, of Amsterdam.

#### BOUTQUETS.

These were by far the most attractive feature of the Exhibition, and we never looked upon anything more brilliant or more tasteful. A table 60 feet long and 9 feet wide, covered with white, had a row of table bouquets down its centre, and two rows of hand bouquets and wreaths on each side, and there were not more than two or three which did not display exquisite taste.

*Wedding Bouquets.*—The first prize was given to W. A. Zaline. Their third row was white Camellias, second row white Lilac, third white Azalea, fourth Orange blossom, centre one white Camellia. A slight sprinkling of green foliage was among the Lilac and Orange blossoms. A deep lace encircled the whole.

*Centre Pieces for Dinner Table.*—The first prize went to A. Bernard. The centre piece was what we might call *Miss March's* design; the dish at the base was filled with Pansies; the stem was wreathed with the Golden-veined Japan Honeysuckle, and the top dish was filled with deep crimson Roses, well relieved by their healthy green foliage. One of the side pieces was a porcelain sarcophagus of an oblong square form, beautifully ornamented, and filled with Roses paler than those in the centre piece, and equally well relieved with foliage. The second side piece was a tureen-shaped vase of porcelain of an oval form, filled with Orchids, *Cypripediums*, and other rare plants, and with a fringe of bright green moss. This was incongruous, both the side pieces should have been alike, and if both had been like the first side piece the three would have been most effective table bouquets.

*Table Bouquets.*—We do not see the distinction between this class and the preceding, and most certainly the three bouquets to which were awarded the first prize in this class were the most effective exhibited, and only suited for the centre of a dinner table. It was to G. Van den Berg. The centre piece was a solid, cut glass shaft, 2 feet high, and the dish at the top had a pyramidal-shaped bouquet, formed of *Amaryllis*, *Chinese Primulas*, *Abutilons*, *Roses*, *Epacris*, *Metrosideros*, *Azaleas*, *Camellias*, and the summit was a plume of *Dracaena* leaves; the whole relieved with fronds of various Ferns. The two side pieces were of similar form to the centre, but lower, and filled similarly.

*Ball-room Bouquets.*—The first prize to M. G. Moens, Antwerp. These were of red and white Camellias, set, as it were, among single flowers of a pale blue Hyacinth, and fringed with fronds of Maiden-hair and other Ferns.

All the hand bouquets were fully 15 inches in diameter, and we will take this opportunity of recording our deprecation of such an excessive size. It is an inexcusable excess, and a lady with such a sheaf of flowers seems encumbered by it.

We have some notes upon the wreaths, but must postpone publishing them until a future opportunity.

#### IMPLEMENTS, ETC.

In the galleries were arranged the implements, garden chairs, books on botany and gardening, ornamental figures, and fruits.

The zinc work, bronzed, was very effective, and creditable to Mr. ———, of Amsterdam, the manufacturer. The flower-baskets, with stands within them on which to elevate the pots to various heights, were very elegant.

In iron work, M. Lebrun, of Brussels, and some other manufacturers, exhibited many articles deserving not only praise, but purchase. Especially so were the garden chairs, with seats and backs formed of arched iron laths, very soft (if iron admits of such description) by being elastic, with stools to match, to keep the feet of the sitter from resting on the ground. The Swiss bird cages were also very light and artistic, and, if anything, would tend to reconcile the prisoner to his confinement.

There was also a *pago la*-shaped pigeonry with a pheasantry beneath, painted to imitate cane, and suitable for placing in, and moving to, any part of pleasure grounds.

One maker had what he termed "a revolving shovel." It is really nine broad hoes fixed on a revolving axis, and pushed or dragged by means of a stout five-foot handle. We should call it "a revolving surface-stirrer," and, in light soils, or garden soil of ordinary loam, we have no doubt it is an effective and rapid-doing implement.

The flower-pots of one manufacturer were very ornamental. The earth bakes of a dark olive colour, and the raised trophies on their sides were bold and artistic. The edges of the pots, instead of the usual monotonous sausage-form, were cut in large half-diamonds. Some were circular, others were of angled forms.

An apple and pear gatherer exhibited for tall standard trees is much more effective and less liable to be out of order than the usual averruncators, as they are sometimes called. It is a pole with a wire cup fixed by a socket to its top, and the edges of the cup toothed like the daisy-rake, which readily divides the stalk of the fruit to be gathered.

Several kinds of garden labels were exhibited, but none novel, and we know that of the old ones none excel zinc, written upon by a proper ink. But there was a little machine exhibited by Ernst Metz, of Erfurt, for the stamping figures on thin leaden tallies, which was a novel application of one of the machines for stamping on paper. The figures 1, 2, 3, 4, 5, 6, 7, 8, 9, 0, are in a row fixed in the foot of the little machine; the strip of lead to be stamped is placed over the desired figure, and a slight blow on an iron handle, the surface of which extends along the row of figures, gives the required impression.

The Exhibition was opened on the 7th to the public, and was well thronged by gentlemen, but the ladies were very few, and, to our English notions, singularly deficient in handsome costume. Our floral fêtes are celebrated for their attendance of beautiful, gracefully-dressed women; but the Netherlands' ladies, perhaps exercising a sound discretion, avoid being compared with the flowers.

#### ROYAL HORTICULTURAL SOCIETY.

*FLORAL COMMITTEE, April 4th.*—An increasing interest seems to be taken in these meetings. Associated as they now are with the scientific purposes of the Society, we may look forward to the enjoyment of many agreeable and profitably-spent hours on the days on which these meetings are held. Few, if any, of the older Fellows of the Society can remember a more beautiful exhibition, even in the most prosperous days of the Regent Street gatherings, than was to be seen on Tuesday last, at the Gardens at South Kensington. It is most gratifying to find that the spirit of horticulture still exists, and that its late ominous symptoms of decay have vanished; and we earnestly hope that every Fellow will do the best in his or her power to impart fresh and continued vigour to all the proceedings of the Society.

The following plants received certificates, Mr. Veitch exhibiting a large collection of plants. A first-class certificate was awarded to *Maranta Veitchii*, a plant with beautiful foliage, the leaves marbled, shaded green. A special certificate was awarded to a group of *Anthurium Schertzerianum*, neatly arranged in a basket, as being a specimen of high cultivation; and a special certificate was also awarded for the general collection in which there were many valuable and well-grown specimens; a basket of young plants of *Azalea Stella* was very conspicuous; *Azalea Mercury*, a rosy lilac flower of good form, a very promising variety, which was requested to be seen again; of *Hoteia japonica*, once known as *Spiraea japonica*, four well-grown plants were exhibited in full flower. This plant was sent to prove its value as an early-forcing flower most useful for table-decoration, or for cutting for bouquets; *Dendrobium macrophyllum*, emitting the most powerful scent of *Rhubarb*—this plant when it produces more vigorous spikes of flowers will be a first-rate Orchid. Several other Orchids of great beauty were to be seen in this collection. We also noticed a *Peperomia* species, *Rhododendron Princess Helena*, &c. Mr. Veitch also exhibited for Mr. Maxwell, two small plants of a variegated *Cineraria maritima*. The sombre grey tint of

the foliage of this plant was not much enlivened by its white variegation.

Messrs. Backhouse, York, received a first-class certificate for a new bright blue *Hepatica angulosa*, the flowers and foliage much larger than the usual form; and for *Phycella* sp. (*Hippeastrum*?), with small, intensely bright orange and scarlet flowers, valuable for hybridising purposes.

Mr. Bull exhibited several new and rare plants, the gem of his collection, and, indeed, of the whole Exhibition, was a superb specimen of *Bertolonia margaritacea*. This plant is one of Mr. Weir's collecting, some few plants of which were balloted for a few years ago, and we regret to learn that nearly all have been lost. As a fine-foliaged plant it cannot be surpassed; requiring the greatest care and the protection of a stove it must remain scarce for some time. A special certificate was awarded for this fine specimen, which had received a first-class certificate in 1862. *Polystichum ordinatum*, also from Mr. Bull, had a second-class certificate, and from the same exhibitor came *Acrophorus variegatus*; *Aralia heteromorpha*, with various forms of leaves; *Cupania undulata*, requested to be seen again; two seedling *Petunias*, *Polygonatum verticillatum argenteo-striatum*, a most beautiful variegated form of Solomon's Seal, exhibited in 1862, by Mr. Standish, as *P. oppositifolium*, when it was awarded a first-class certificate; *Polygonatum verticillatum aureo-striatum*, the plant too small for determining its merits; and *Adiantum robustum* with one frond. Mr. Bull's collection contained fine specimens of *Camellias*, *Imantophyllum*, &c., and received a special certificate.

J. J. Blandy, Esq., sent two large boxes of cut *Camellias*; some cut specimens of a dull red *Camellia* with a blue metallic tint, supposed to be an Italian variety, but the name could not be ascertained; also some cut specimens of *Salvia Regia*, with bright scarlet spikes of medium-sized flowers, useful as a decorative plant. The seeds of this *Salvia* were sent to the Society by their collector, Mr. Hartweg, twenty-five years ago, and was considered one of the good things of former days. Mr. Pilcher, gardener to S. Rucker, Esq., sent several valuable *Orchids*. First-class certificates were awarded to *Cypripedium concolor*, a new and distinct form of this genus, a dwarf-growing plant, pale yellow flowers, minutely spotted, with broad oblong wings; *Odontoglossum Lindleyanum*, one of Mr. Weir's collecting, dull yellow flowers with large brownish markings; *Chytroglossum manicæ-leonis*, a miniature form of *Orchid*, both rare and new, bearing a graceful little spike of greenish flowers, the wings strongly marked with white lobes: this plant received a certificate as a botanical curiosity. John Day, Esq., sent several fine *Orchids*, and first-class certificates were awarded to *Oncidium amictum*, *Odontoglossum gloriosum*, very handsome and worthy of its name; also *Dendrobium lituiflorum*, which received a first-class certificate in 1863. Among the collection were *Leptotes tenuis*, Brazil, with singular Rush-like foliage, and an *Orchid* from Assam with brown and yellow flowers on an erect spike, very distinct, and apparently not known. Mr. Jay, Norwich, sent a seedling *Cineraria*, Queen of the Beauties; and Mr. Williams, Holloway, received a first-class certificate for *Colocasia longiloba*, the white stem beautifully marked with fine black lines, a distinct variety in this numerous and variously-named family. Mr. Williams also sent *Phalenopsis amabilis*, a distinct and fine variety, dark spotted centre, and very dark green foliage, the flowers more circular in the outline than the usual form; and an *Azalea*, *Alexandra*, a white flower with too green a centre. A special certificate was awarded for the general collection, which contained fine specimens of *Yucca filamentosa variegata*, *Pandanus reflexus*, *Dasyliiron acrotichium*, *Hemerocallis Kwanzo flore pleno*, *Pandanus elegantissimus*, and *Xanthorrhoea australis*. Mr. Turner sent cut specimens of two splendid new Hybrid Perpetual Roses, both of first-rate quality, *Pierre Notting* and *Madame Victor Verdier*.

W. W. Saunders, Esq., again contributed largely from his valuable collection of plants. First-class certificates were awarded to *Miconia flammea*, one of Mr. Weir's plants, fine handsome foliage; *Cinchona nobilis*, an interesting medical plant, and one of those from which quinine is prepared, which we regret (though doubtless unintentionally), was not taken notice of. *Pelargonium filipendulifolium*, with very curious, long, cut leaves, most useful for covering hanging-baskets, was awarded a special certificate. Among

other curious plants in Mr. Saunders's collection was a specimen of *Dorstenia* from Old Calabar, with singular green inflorescence. Mr. Hooper sent a seedling *Amaryllis Hooperi*, as good as *Amaryllis Sweetii*, which it too much resembled.

Mr. Salter, Hammersmith, exhibited six pots of *Convallaria multiflora variegata*, for which a special certificate was awarded. We cannot speak too highly of this beautifully variegated form of the *Lily of the Valley*; there is an elegance in the white-lined variegation peculiar to itself. This ornamental-foliaged plant should be in every collection. Messrs. Cutbush sent fine collections of *Hyacinths*, *Tulips*, and *Narcissi*, each of which received a special certificate. Messrs. Cutbush also sent three pots of well-grown forced *Solomon's Seal*, and three new *Hyacinths* of 1865—*Hogarth*, a single shaded rose with white centre, a very promising variety, taking the place among the reds which *Argus* does among the blues; *Cuvier*, a fine, single, deep, shaded blue, very good—first-class certificate; and *La Française*, a single white faintly tinted with pink, a very fine spike with large bells—first-class certificate. Among the novelties of the day we noticed a table liberally supplied by the Council with refreshment for the members of the Committees, which was most gratefully accepted by them.

FRUIT COMMITTEE.—G. F. Wilson, Esq., F.R.S., in the chair. Although prizes were offered for dessert Pears, dessert and kitchen Apples, and forced Strawberries, the subjects for examination were very limited. Mr. Ruffett, gardener to Viscount Palmerston, had a first-class certificate for the following Apples—viz., *Ashmead's Kernel*, very good, *Claygate Pearmain*, *Pearson's Plate*, not so flat as usual, *Old Nonpareil*, perhaps the best flavoured of those exhibited, *Golden Harvey*, and *Sturmer Pippin*; in addition to which he had fine examples of *Scarlet Nonpareil* and *Grange's Pearmain*. To Mr. Cox, gardener to W. Wells, Esq., *Redleaf*, a second-class certificate was awarded. Among his collection were *Formosa Pippin*, *Nonpareil*, *Court of Wick*, *Russet Nonpareil*, *Ribston Pippin*, *Hampshire Yellow*, *Fearn's Pippin*, *Scarlet Pearmain*, besides which there were *Brabant Bellefleur*, a kitchen Apple, and an Apple called *Golden Harvey*, but to all appearance not that sort.

The only exhibitor of Strawberries was Mr. A. Ingram, gardener to J. J. Blandy, Esq., Reading, who had a good dish of *Keens' Seedling*, for which he received a first-class certificate, and he likewise contributed a dish of *Ne Plus Meuris Pears*. A special certificate was awarded to Mr. Chapman, gardener to His Highness Halim Pacha, *Shoobrah Palace*, Cairo, for a small collection of fruit, consisting of two large and fine seedling Lemons; a large, round, and somewhat flattened Orange of a deep reddish orange colour; a green and white speckled fruit; and two kinds of Nuts brought from Upper Egypt by *Mehemet Ali*, but what these fruits were neither Mr. Chapman nor any of the Committee could determine. Mr. Chapman also sent *Ash-leaved Kidney* and *Early Handsworth Potatoes* planted in the end of last November, and taken up in the beginning of February this year. The Potato, Mr. Chapman observed in a letter to the Committee, was not cultivated in Egypt, but from the specimens sent, which were very clean, healthy, and well grown, there could be no doubt that it might be successfully grown in that country.

A SCIENTIFIC meeting was held on the same day as the above Committees, J. J. Blandy, Esq., in the chair.

The Chairman regretted to inform the meeting, that in consequence of illness, the Rev. M. J. Berkeley was unable to attend, but the Rev. Joshua Dix, and G. F. Wilson, Esq., the chairmen of the Floral and Fruit Committees, would read over the list of awards, and offer what remarks they might think necessary, after which Mr. Bateman would make some observations, more especially with regard to *Orchids*.

Mr. Bateman regretted that Mr. Berkeley had been laid up, but a paper had been sent by that gentleman with reference to the Chinese *Primulas* exhibited at the last meeting, and which would now be read by Colonel Scott.

In this Mr. Berkeley stated that he had at the last meeting called attention to a peculiar variety of Chinese *Primrose* in the collection of Messrs. Windebank and Kingsbury, of Southampton, which he had found to differ from all the monstrous forms described by *Kramer*. Each stamen was

replaced by a flower more or less perfect, the parts in some being like ordinary petals, in others like complete florets, in others again merely hollow tubes or threads. Among Primulas, continued Mr. Berkeley, there were two forms of flowers, the pin-eyed and the thrum-eyed, and Mr. Darwin had shown that these two forms differed in fertility according as they were impregnated. The thrum-eyed, unless impregnated artificially, are barren, but if the pollen of the pin-eyed be applied to them they produce more seed than the pin-eyed when impregnated with the thrum-eyed. Impregnating with pin-eyed flowers was the easier mode, but the quantity of seeds produced was small. It would be interesting to find out whether the best flowers in a florist's point of view came from the thrum-eyed or the pin-eyed, and information on that point would be desirable.

Mr. Bateman then commenced by directing attention to some rare Cyripediums which were exhibited. The name had been given to the genus by some gallant classical botanist, and signified Venus's slipper, but he hoped Venus did not, like a slattern, wear her slippers down at the heels like all the species of this genus. Thirty years ago there were only two species in this country, but now there were twenty distinct kinds; and, having had the privilege of inspecting Dr. Lindley's herbarium, he could say that it contained dried specimens of many more yet to be introduced, especially from South America, and which would vie in beauty with the very best of those which we now possessed. They had before them a specimen of *Cyripedium hirsutissimum* from Mr. Veitch, and one of *C. Lowii*, which had been introduced from Borneo by Messrs. Low of Clapton, and though the plant coming from Mr. Veitch was well grown, it yet gave but an imperfect idea of what it would ultimately be. Another very interesting species to which he would now refer was sent home by the Rev. Mr. Parish, an Indian missionary, and differed from all tropical *Cyripediums* in the leaves being purple beneath and beautifully marbled above, while the flowers were yellow. It had been named concolor, and a description and plate of it would shortly appear in the "Botanical Magazine." *Cyripediums* were very easily grown, and lasted in flower for a length of time, and it would be very interesting for ladies and gentlemen to form collections of this genus alone. All of them would succeed under cool treatment, and persons about to commence Orchid-growing on a small scale could not select a more suitable genus of this glorious tribe of plants. The next genus of cool Orchids which he would mention was the *Odontoglossums*. They were found growing at an elevation of 5000 feet in New Grenada, Mexico, and Peru, and they were rapidly rising in popularity and favour, and were as easy to manage in the climate of a warm greenhouse as any other Orchid. *Odontoglossum Pescatorei* had been in bloom for two months, and was likely to last for two months more, and he would mention that Mr. Anderson, of Meadowbank, had grown it with as many as a hundred flowers on a spike. *Odontoglossum pulchellum*, of which a plant was exhibited by Mr. Rucker, having snow white blossoms, was peculiarly well adapted as an ornament to ladies with dark hair or dark silk dresses, and it had this property, that the flowers might be used at half a dozen different balls or *soirées*. *Odontoglossum gloriosum* was another splendid species, found at an elevation of 9 or 10,000 feet in the Andes, near Bogota. It had been introduced by the Society, and subsequently by Messrs. Low, and wild specimens had sometimes a hundred flowers on a spike. A third species was *Odontoglossum Lindleyanum*, so named by Dr. Reichenbach in compliment to his brother Orchidist Dr. Lindley. It had also been received from Mr. Weir. Of *Ceologyne cristata* a specimen was exhibited by Mr. Veitch; it was also capable of cool treatment, coming from the slopes of the Himalayas. It would remain in bloom for weeks, nay months, and was so easily flowered that a traffic was springing up with it at Covent Garden and Manchester. Its colours were white and gold, and hence it was sought after for bridal bouquets. *Chysis bractescens* presented the same colours, and could be used for the same purpose; and still more beautiful was *Phalenopsis amabilis*, which was also before the meeting. Mr. Bateman related that when this Orchid was first sent over from Manila to Messrs. Rollisson of Tooting, the late Duke of Devonshire was so struck with its beauty that he wanted to purchase it; and

though informed that it was not for sale, would take no denial, but gave Messrs. Rollisson a blank cheque to fill in with whatever amount they valued it at, and they put down £100; but in consequence of the importations which had been made, plants of it, however, might now be had for as many shillings. *Dendrobium lituiflorum* and the New South Wales *Dendrobium speciosum* were then referred to. The latter, it was observed, was twenty years in this country before it flowered; and the reason of this was, that in former days the atmosphere of Orchid-houses was kept so warm and moist, that luxuriant leaf-growth was encouraged at the expense of flowers; but cultivators had become alive to the importance of a more sensible mode of treatment—only keep it cool, and nothing could be more easily grown, it would then flower as readily as the least shy-flowering of the race. To any one desirous of cultivating a particular genus of Orchids, *Dendrobium* alone would furnish two hundred species. He would now notice a small box of beautiful cut flowers, which had just come from Mr. Day, of Tottenham, among which were *Dendrobium Farmeri*, a Mexican Lycaste, a *Cattleya*, a *Galeandra*, a *Leptotes*, a *Ceologyne*, and *Oncidium nubigenum*, which produced spikes a yard long and grew at an elevation of 10,000 feet, in regions of snow and hail, and even frost, teaching the lesson that a vast number of Orchids could be grown in an ordinary greenhouse temperature. Before leaving *Dendrobiums* he must notice a new species, though not in flower, sent by the Rev. Mr. Parish to Messrs. Low, and which was called *senile*, being covered with white hairs, and being among Orchids what the Old Man Cactus was among that family. The flowers were golden yellow, and he (Mr. Bateman) had no doubt that it would create quite a furor in time. Mr. Bateman then briefly noticed the other plants shown, among which were *Chytroglossum manicæ-leonis* and *auratum* from Brazil, and *Hepatica angulosa* from Messrs. Backhouse, the latter not a mere variety, but a new and (as the meeting would perceive), a very handsome species, and which, he had no doubt, would prove perfectly hardy, as he saw it coming vigorously in bloom after standing the winter in North Staffordshire. There was also a species of *Phycella* from Messrs. Backhouse, the orange scarlet flowers of which were the most brilliant colour he had ever seen in the vegetable kingdom, in that respect far exceeding even *Lælia cinnabarina*. *Bertolonia margaritacea*, which was exhibited by Mr. Bull, was another plant of great beauty, the foliage being sprinkled all over as if with pearls, on which account it had received its name, *margaritacea*. Other plants of interest were *Polygonatum verticillatum*, Mr. Bull's *Imantophyllum miniatum* from Natal, a variegated-leaved Lily of the Valley from Mr. Salter, which was likely to be very popular, and *Ficus Cooperi*, of which the habitat was uncertain, but it had probably come from the Indian Archipelago. The fruit was also there, but it had not been ascertained whether it was poisonous or not. Though Figs were wholesome in general, some were poisonous; but he hoped that some zealous horticulturist would come forward in the interest of science, and, *pro bono publico*, eat the Fig, and so settle the point. The Fruit Committee, whose duty it was to taste all fruits submitted to them, had wanted the courage to put the matter to the test. Mr. Bateman then brought under the notice of the meeting what were called branch pots. Among Orchids some grew in the clefts of branches, and others sent roots along the arms of trees. The latter would not grow in ordinary pots, and were therefore kept on blocks; but after a few years, and sometimes a few months, a fungus appeared which destroyed the roots, and it became necessary, therefore, to shift the plants to other blocks. With large plants this was not of much consequence, but in the case of tender Orchids the matter was more serious. Having a scarce *Chytroglossum* to remove, he was led to consider whether something could not be invented which would prevent the necessity and danger of reblocking so frequently, and the idea occurred to him of having models of branches of trees made of pottery, and perforated at places; and the plants which he had tried in such branch pots had succeeded perfectly, and he had every reason to believe that shifting would not be required for many years. It appeared, however, that the idea of employing pottery to obviate the necessity of shifting had also occurred to Mr. Rucker, for on going to his place he found

plants growing on a drain-tile. Mr. Bateman stated that the blooms of the *Odontoglossum pulchellum*, shown by Mr. Rucker, and the *Camellias* shown by Mr. Blandy, had been kindly presented by these gentlemen to be balloted for by the ladies present.

With regard to the Tuesday meetings he wished to state that they had no connection with the Saturday shows, the latter were for miscellaneous plants; but to the Tuesday meetings anything new or curious should be sent. These, it had been arranged, were to take place every alternate Tuesday.

The meeting, we may remark, was even more numerously attended than the last, and the observations made by Mr. Bateman were listened to with the greatest attention.

**WEEKLY SHOW, APRIL 8TH.**—On this occasion Mr. Bull contributed specimens of *Drynaria musæfolia*, *Marattia elegans*, *Dicksonia antarctica*, *Gleichenia flabellata*, and *Athyrium Filix-femina sagittatum*; Messrs. Lee, stands of cut *Camellias*; Mr. Ingram, gardener to Her Majesty, Frogmore, forced Pinks and Roses, Asparagus, Mushrooms, French Beans, and two excellent Pines (Smooth and Prickly-leaved Cayenne); and exhibitions of the usual character came from Messrs. Lucking and Greeves.

Her Majesty, accompanied by their Royal Highnesses the Princesses Helena and Louisa, and Prince Alfred, visited the Gardens on Thursday, the 6th inst.

### THE ROYAL BOTANIC SOCIETY'S SECOND SPRING SHOW.—APRIL 8TH.

The day was lovely, with bright sunshine and a soft mild atmosphere, and, as if in rivalry, the Roses had put on their rich robes of purple and scarlet—regal colours befitting the queen of flowers—while the Azaleas, Hyacinths, and Tulips were clothed in all the magnificence of oriental attire. The glow of colour which the tent presented was brilliant in the extreme, and this, coming after the cold and cheerless weather which we have passed through, made it seem as if at one bound we had sprung from winter into summer.

In Azaleas Mr. Turner of Slough, as usual, stood pre-eminent, his plants being covered with bloom, but having just enough of foliage apparent to relieve a blaze of colour, which otherwise would have been overpowering. They consisted of *Iveryana*, *Holfordi*, *Criterion*, *Prince Jerome*, *Flower of the Day*, and *Empress Eugénie*. Mr. Williams of Holloway came next with, among others, *Delecta*, *Countess of Stamford*, rich salmon scarlet, *Rubra plena*, and *Model*. Messrs. Lane were third, and they likewise contributed a numerous collection, which included *President Claeys*, *Madame Verschaffelt*, *Advance*, *Duke of Cambridge*, and other recent kinds, and many others older and better known. Among amateurs Mr. Todman, gardener to R. Hudson, Esq., Clapham Common, Mr. Wheeler, gardener to Sir F. Goldsmidt, Bart., and Mr. Young, Highgate, exhibited plants in good bloom, for which prizes were awarded in the order in which these exhibitors are named. In new kinds Mr. Turner was first with *Mars*, splendid orange scarlet, *Madame A. Verschaffelt*, pale rose bordered with white, and having crimson spots, and *Advance*, bright rose, another fine flower. Messrs. Lane came next with the two last-named and *Duke of Cambridge*, a large flower, rosy crimson with violet crimson spots; Mr. Todman being third with *Flag of Truce*, the best of its class, *Prince of Orange*, a beautiful orange red of fine form, and *Madame A. Verschaffelt*.

Of Roses, gorgeous plants in pots were furnished by Mr. W. Paul and Messrs. Paul & Son. Among those particularly noticeable were *Victor Verdier* with immense blooms, *Sensateur Vaisse*, *Beauty of Waltham*, *Jules Margottin*, Mrs. William Paul, very rich in colour, *Pierre Notting*, dark red shaded with violet, *John Hopper*, *Paul Delameilleray* fine glowing colour, *Le Rhone*, *Lord Clyde*, *Maurice Bernardin*, *Noisette Celine Forestier*, and *Teas President*, *Madame Willermoz*, *Rubens*, *Madame de St. Joseph* in splendid bloom; *Madame Damazin*, with a profusion of its salmon-coloured blooms; and *Marquise de Foucault*. Equal prizes were awarded to both exhibitors; and for boxes containing very fine cut blooms of the above and numerous other varieties, Messrs. Paul & Son were first, and Mr. W. Paul second,

the latter receiving in addition a first-class certificate for the new Tea Rose *Maréchal Niel*, with large, deep yellow, delightfully fragrant flowers, a variety which will doubtless take a prominent position among the Roses of its class. A new Hybrid Perpetual, *Princess Mary of Cambridge*, came from Messrs. Paul & Son; the colour was pale pink, with a flush of rose in the centre.

Hyacinths were again shown in large collections and in fine condition by Mr. W. Paul and Messrs. Cutbush, the latter also contributing fine collections of Early Tulips and *Narcissus*; whilst Messrs. E. G. Henderson again exhibited their beautiful *Cyclamens*. Of *Cinerarias*, too, there were good exhibitions from Messrs. Dobson and Mr. James, of Isleworth. The best were *Duke of Cambridge*, crimson self; *Lord Elgin*, rosy purple self; *Snowflake*, white with a dark disk; and *Miss Smith*, white, with a violet blue edge and dark disk. Prizes were given for both the above exhibitions; and Mr. Marcham, Hanwell, had a first-class certificate for *Lord Amberley*, a large-flowered, rich, violet plum self.

Miscellaneous flowering and fine-foliaged plants were exhibited by Messrs. Lee, Williams, Wheeler, and Young, and comprised Azaleas, *Hedera*, *Eriostemon buxifolium*, *Epacris*, *Tethraea ericæfolia*, *Vanda tricolor*, *Yuccas*, *Dracænas*, *Dicksonia antarctica*, *Cyathea Smithii*, *Cordyline indivisa*, *Maranta zebrina*, and *Pandanus javanicus variegatus*. Good plants of fine-foliaged *Begonias* were shown by Mr. Young, Mr. Wheeler, and Mr. Marcham, but did not present any novelty. *Camellias* and a collection of *Dracænas* came from Mr. Bull; also *Achyranthes Verschaffeltii*, which is the same as *Iresine Herbstii*, striped *Polygonatum verticillatum*, and *Bertolonia margaritacea*. To the latter a first-class certificate was given, and a similar award was made for *Camellia Bicolor de la Reine*, delicate rose edged with white, a very promising variety. Mr. Williams had first-class certificates for *Colocasia longiloba*, described in our Floral Committee report, and *Alsophila latebrosa*, with graceful spreading fronds. F. J. Graham, Esq., Cranford, likewise received a first-class certificate for his large-flowered Russian Violet, *The Czar*, which has been previously described, and to show the difference in point of size it was accompanied with flowers of the old kind. From Mr. Holland, gardener to R. Peake, Esq., Isleworth, came a nice collection of British Ferns, among which *Asplenium trichomanes Harrovii*, a slender, bright green, very pretty variety, received a first-class certificate; and from Mr. Bartlett, Hammersmith, some pots of *Lily of the Valley*.

### MANETTI RECOLLECTIONS.

I RECEIVED from Mr. Harrison, of Darlington, the following Manetti recollections with permission to make use of them:—

"I am glad you are going to say a few words on the Manetti Rose stock. I am always pleased with your interesting articles on Roses and Rose-growing. The Rose has always been my favourite flower for upwards of fifty years, long before Perpetuals and Bourbons appeared. When I was a boy, twelve years of age, I went into the woods adjoining my father's nursery at Yarm, and budded Briars with Roses. I am now in my sixty-fifth year. Had it not been for the Manetti Rose stock one-tenth of the demand for Roses could not have been supplied. I came by the stock in the following way. It is due to Mr. Rivers. In the year 1842 I left the Yarm nursery, and went to York, and took some nursery ground. Mr. Thomas Appleby also commenced at York in the same year. We were, and are still, on friendly terms. We at that time purchased all our new Roses of Mr. Rivers—the dwarfs worked on the Dog Rose; and new Roses were then thought a great treat to get hold of the third or fourth year after their introduction (and then, perhaps, they were poor stunted plants), at from 5s. to 7s. 6d. each. Grafting was not then thought of, and we had to wait for the budding season. Half a dozen buds were considered a fair supply for a new Rose; and then we had to wait three or four years before we could supply the demand in the country. What will the gentlemen say to this who condemn the Manetti? When Mr. Rivers called on me at York Mr. Appleby put the question to him, 'Is

there no stock upon which Roses could be propagated quicker than on the Briar?" Mr. Rivers immediately said (the words are as fresh in my mind now as when he uttered them), "Well, I have a stock recommended to me called Manetti, but I have not used it much, and therefore I cannot say." We ordered 100 each; and then the third year after this, when Mr. Rivers called again, he was utterly astonished at the growth of the Roses on the Manetti. Mr. Appleby began to write about it, and sold a few dozens to the trade. I tried to persuade him to keep quiet only for four or five years, and we should both make a fortune, but he would not wait. I kept propagating on till I had nearly 100,000 of it, besides sending out all my dwarf Roses upon it. I may venture to say that I have made £100 a-year by the sale of this stock alone. I have sold it as low as 40s. per 1000; but this year I have sold none under 80s. per 1000; and I could have sold 50,000 since I disposed of all I had to spare. My stock next year will be immense. I keep two boys cutting out all the eyes, to prevent suckers, except two eyes at the top."

I have never seen three dozen suckers from the roots in my life. Briar Roses are very troublesome in this respect. The Manetti suckers are from the stock. Before you plant cut out the eyes, and tread the soil hard against the stock, and you will not be troubled, certainly not after the first year.—W. F. RADCLIFFE, *Tarrant Rushton, Blandford.*

### STRAWBERRY CULTURE.

THE discussions which have been raised about La Constante afford one more proof of the strange vagaries of the Strawberry. Most persons agree that two of the very best sorts are Rivers's Eliza and Carolina Superba. I have given both these sorts ample trial. Of the quality of Eliza there can be no question; but both in the open air and under glass I found it a poor bearer, and so loth to put forth runners that propagation became difficult. As to Carolina Superba, it was inferior in every respect to both its reputed parents—namely, British Queen and Old Pine. On the other hand, Old Pine and Downton are usually considered bad bearers, but I do not find much cause to complain of them in this respect.

I proposed to a wire manufacturer last year to make some protection for Strawberries upon the principle of the Pea protectors, lately brought out at a shilling per yard run. He said they would be too expensive for general use. I wish Mr. Wills, who has so cleverly made the curate's viney to fold up, would contrive something of the kind, made in wire, for Strawberries. The difficulty of stowing such things away in winter is as great a drawback as first cost.

I recommend Strawberries to be cultivated two rows in each bed, the rows 18 inches from each other, the plants 1 foot apart in each row. After the first year's fruiting destroy each alternate plant, and fruit them one year more. To cover such a bed the protectors need not exceed 3 feet in width, and 15 inches in height over the crowns of the plants would probably be sufficient.

After the second year's fruiting I give my beds one year's rest from Strawberry culture by planting them with late Siberian Broccoli. These are off the succeeding May, and the beds are ready to receive either the earliest runners that can be had in July, or any of the preceding autumnal runners which have been planted in a reserve-bed. These last, however, will require 18 inches from plant to plant.—G. S.

P.S.—Allow me to ask if Mr. De Jonghe is correct when he says (page 233 of your Journal), that Strawberries must not be removed with a ball?

### MY ORCHARD-HOUSE ON APRIL 7TH.

IN giving a few words of record I have stated the date, because I think it will be interesting to some of your readers to know the periods of the blossoming of orchard-house trees in different parts of the empire, and by-and-by the periods of the ripening of the fruit—especially so, I think, if Mr. Bréhaut will add a date to his few pleasant words.

My Apricots, which have been masses of blossom these ten days past, have now set their fruit in myriads. I am

always at a loss to account for the failure of Apricots under glass which I sometimes hear of, for here they cannot be persuaded to fail, every tree, however small, setting quantities of fruit.

I read in Mr. Fish's "Doings" of his painting his trees with some not very agreeable composition, and of the trouble he seems to be in with birds out of doors and brown beetles within. I presume he means the common brown Peach aphid (*Aphis persica*), and I feel curious to learn why he calls them beetles. I suffer but little from them, for in my large house full of old trees, which is never fumigated, not one is to be seen. The simple remedy used here, 4 ozs. of quassia chips, and 4 ozs. of soft soap, to a gallon of soft water, boiled ten minutes, is always kept ready, and when applied with a brush never fails to kill them. I dislike painting the trees, it so spoils the beauty of their buds and blossoms.

I used formerly to wash my trees in December with a weak infusion of Gishurst, 4 ozs. to the gallon, but have now ceased to do so. My Peach and Nectarine trees are now in full bloom, and charming objects they are. It may be that Mr. Fish's houses are old and confined, which is the reason he is so troubled with insects.

Birds abound here, and at one time gave me much trouble by eating the buds of Plums, Cherries, and Gooseberries in winter and spring, but since I have had white worsted twisted round the ends of the twigs, so as to form a sort of net, with meshes 2 or 3 feet in diameter, not a bud has been touched. I should like Mr. F. to tell us if he has tried this should-be preventive. Perhaps Bedfordshire birds are more voracious than ours of Hertfordshire.

I almost fear I must complain of the bees which throng to my house in multitudes—for this reason, they are so numerous and so active that by 11 A.M. all the pollen is clean gathered from the anthers, and the little fellows are off with their golden balls of dust attached to their thighs. I searched yesterday about 12 for some pollen to fertilise with, but all was gone—yet there are hundreds of Peach and Nectarine trees in the house, and every tree crowded with blossoms. My fear is that the pollen will be cleared off before it has done its office. Oddly enough, I do not know of a single stock of bees in the neighbourhood.—T. R.

### LA CONSTANTE STRAWBERRY.

HAVING grown La Constante three years I may, perhaps, be allowed to add a word or two to the discussion going on in your pages as to the merits of this fine Strawberry. In the first place I consider it thoroughly hardy.

Mine is a cold soil, becoming sodden and sticky in wet weather and very hard and dry in time of drought, but I have not as yet found La Constante suffer from either heat or cold. It is not a strong, but it is a healthy-growing variety, and runs enough, and soon enough to satisfy me. In this latter respect it would not, I dare say, satisfy a nurseryman who wanted to obtain a large stock quickly. It certainly is not soon over; on the contrary, it continues a long time in bearing. The fruit is not what I should call large, but it is of a fair size, and very handsome, and true to what I may call its typical shape.

As for flavour, in my humble opinion, no Strawberry approaches it, even British Queen, and I am borne out in this opinion by some friends who tasted it here when they came to see my Roses last June. I do not, however, think it can be called a heavy cropper. To sum up, I think that

1. It is a variety of healthy, though moderate, growth.
2. It is perfectly hardy.
3. It runs sufficiently.
4. It is fair-sized and very handsome.
5. It is unsurpassed in flavour.
6. It lasts a long time in bearing; but,
7. It is not a heavy cropper.

Mr. Radclyffe says it would be a good parent to raise seedlings from. Will he be so kind as to suggest which cross he would prefer?—the pollen of La Constante to President, or *vice versa*. I made a number of crosses last year, amongst others La Constante and Filbert Pine, using the latter as the seed-bearer. I should be glad of any hints on this subject.—P.

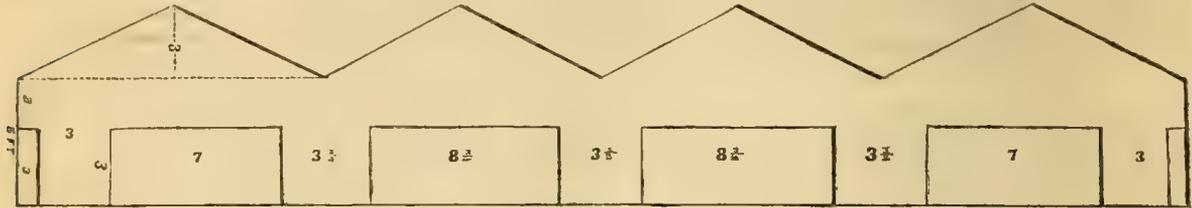

CONSTRUCTION OF A PINE STOVE.

HAVING the intention during this summer to build a fruiting Pine-stove, the idea has occurred to me, that as the building of such houses has not been much discussed of late, you might, perhaps, be induced to publish my plans, and that by this means others who had the like intention might meet me in the same spirit, or, failing these, some one of more matured knowledge would, perhaps, tell me where the weak points in my plans are. Building hothouses is not to be undertaken lightly, especially when there is an intention of deviating from established forms.

I will try not to enter upon the cultivation of the Pine Apple any farther than is necessary to explain my views, as

I cannot lay claim to having it at my finger-ends, much less can I point to the prizes I have won; suffice it to say I am only forming the plans of what is to be my first fruiting-house.

Let us commence with the clear understanding that what I want is a house capable of ripening Pines at any period of the year; and therefore one in which a summer heat cannot be kept up in spite of any weather, I must consider does not come up to my standard. The next point is the cost of erection. This I cannot go into, even if desirable, but I think I can make my idea clear enough without doing so. I will take instead the size of houses required to give a

No. 1.—SECTION.

fixed number of square feet of pit room; in my plan there are 1351. See ground plan No. 1. The house is 50 feet long and 48 feet wide, and in it there are four beds—  
 Two are 44 ft. x 7 feet = 308 x 2 = 616 } = 1351 square ft.  
 Two are 42 ft. x 8 ft. 9 in. = 367 1/2 x 2 = 735 }

Plan No. 2 is a lean-to 193 feet long by 14 feet wide, the one bed is 187 feet x 7 feet = 1309 square feet. I have

given it the advantage of a half span, but when the back wall is reduced by this means to 8 feet high it is still evident to all that the expense would be too great.

Plan No. 3 is that of a span-roofed house 100 feet long and 24 wide; in this there are two beds 94 feet x 7 feet = 658 x 2 = 1316 square feet. This house, you will see, I have made twice the length and half the width of mine; and the height, by the dotted line, from the top of the beds to the apex is 6 feet.

Thus the choice as regards cost rests between Nos. 1 and 3, but I am afraid I must throw out No. 3, because it would be next to impossible to keep up the required heat by 30° or more during such cold windy days as we have had of late. No. 1 is nearly square: therefore, as the wind only blows on one side at once, it cannot have more than 50 feet in length exposed to its action. No. 3 exposes double that length. Again: No. 1 has four spans of 12 feet each, No. 3 one of 24 feet. For a 12-foot span the roof should rise 3 feet above the sides, and for a 24-foot span 6 feet. No. 3 then, in addition, exposes 100 feet by 3, or 300 square feet of roof to the direct action of the wind more than No. 1. If any one knows of such a house that can be kept up to my standard of 90° in any weather, I shall be glad to hear how many rows of pipes it has. I am proposing to give mine six rows next to each side, and four rows in each path, making twenty-four rows in all of four-inch piping.

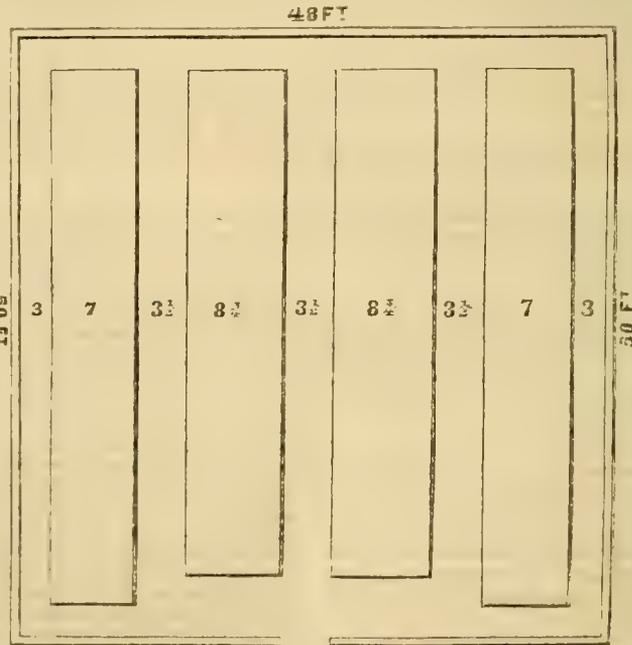

I will now take the question of bottom heat, and I think

it is one that has been much neglected. I have often seen in your paper and elsewhere plans given of houses that are supposed to be good, after this fashion: in a seven-foot pit four rows of four-inch pipes covered with rubble, and above the rubble the pit is filled with plunging material, the bottoms of the pots coming within a foot of these pipes. Now, in a seven-foot pit there is only room for three rows of

large fruiting plants, so these plants have one-four-inch pipe and a third each. Mr. Rivers told us a short time since the heat he supposed he obtained for his pot Vines by standing them on a bare four-inch pipe; I do not remember it now, but I think it was much more than Pine-growers would like to use. I therefore can only conclude that by this plan the heat is lost; and I have a very strong opinion that if, instead of these four rows of pipes being buried in the rubble, two of them were put under flags or a four-and-a-half-inch brick arch, they would give a bottom heat of 100° without any assistance from plunging material; but I think there is yet another mistake—a pipe is not very hot if when water is poured over it no steam is given off; and will not these pipes, if they are hot enough to do any good, from this cause continually tend to spoil the drainage, even if they do no harm to the roots of the plants?—G. H.

[In accordance with your wish, we will add a few remarks just as they occur to us.

1. Your plan, No. 1, consisting of a space 48 feet by 50, divided into four spans, and four beds below these spans, is, we think, new as applied to Pine-beds, but the idea is not new so far as combining different spans, even if each should form a distinct house, as descriptions of such houses at Messrs. Lanes', in previous volumes, would testify. Sections of similar houses were also given in "The Heating Manual." That, however, does not render your plan less desirable.

No. 1.—GROUND PLAN.

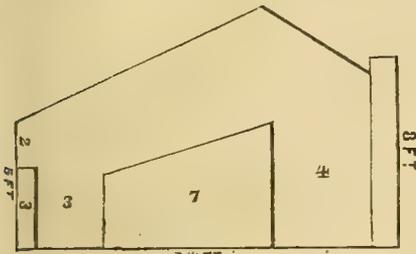

One advantage you will derive is the uniform depth of your beds under each span, so that the light will play on both sides alike. Three feet in depth will be ample, with pipes below for heating, whether you use plunging material or soil, and provided the pipes are not far from the pots we do not think it matters what you cover them with. We should think three pipes in each bed ample.

2. The side walls, brick 3 feet and glass 2 feet, being 5 feet, the height to the apex 8 feet, and the height to the gutter between the ridges 5 feet, a tall man could not walk upright even along your central pathways. They ought to be at least a foot more in height, and the apex or ridges in proportion. This will necessitate a greater surface of glass, and thus so far interfere with your calculations. It would be premature to say anything as to how the house and roof are to be braed, &c., but stout side walls are a great advantage in this respect.

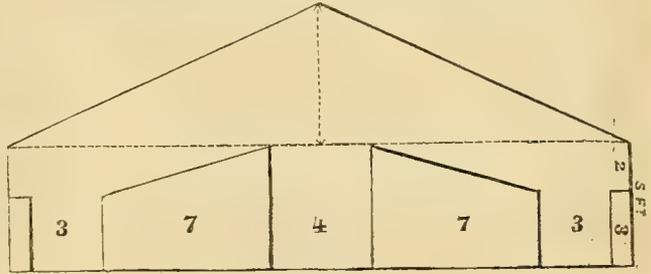

3. In your plan, No. 3, there would be more glass for the

space exposed to the direct action of the wind; and though piercing winds tell much in cooling the glass they come but seldom, whilst in cold and frosty weather there is a continual radiation of heat, unless when a bright sun is shining on it, and then the heat inside will be more equable in proportion to the amount of atmospheric air enclosed. The ridge in No. 3 might also be a foot lower without detriment. If the central pathway were 3½ feet, as in No. 1, and the addition put to the beds, you would have nearly 100 feet more. By making two spans of the roof of No. 3, it would be just the same as the half of No. 1, and the side walls would give strength to the structure. You certainly gain in your proposed arrangement of one large house, in saving one pathway. So far as radiation of heat is concerned, the mere form of the roof enclosing a similar space is of but little consequence.

4. If such a large house were to be entirely filled with fruiting plants about the same stage, we could see no ob-

PLAN No. 2.

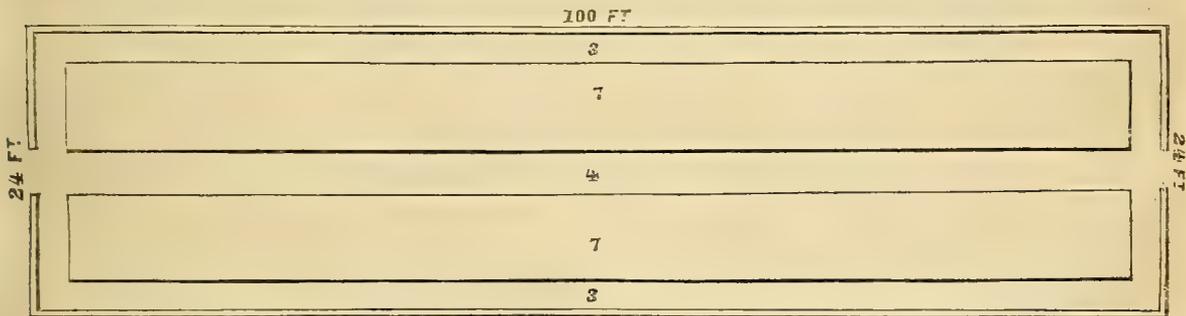

PLAN No. 3.

jection to it; but if different beds contained plants in different stages of growth, we would rather prefer being able to give them different treatment as respects temperature and atmospheric moisture. In such a case the hipped lean-to of No. 2, or the span or rather double span-roof of No. 3, with several divisions in the 100-foot length, would please us better. That is no reason, however, why you should not carry out your own proposed plan.

5. Some thirty years ago we helped to manage a house for Vines and Pines very much the same as your section of

No. 3, only it was some 3 feet higher at the apex, and the central path was elevated so as to be about 1 foot below the stone curb of the Pine-beds. The Vines were brought in below the wall plate at each side. The house was heated by a flue on each side, and also by another beneath the central pathway. The side flues were only worked in severe weather in winter, for fear of starting the Vines. When the Vines were started all were put in action. The house was kept at very nearly 60° by means of the centre flue, bottom heat being given by tan, and Pines did well as suc-

No. 3.—GROUND PLAN.

cessions, and fine Grapes were also obtained. Hot water was just then becoming popular. The gardener was celebrated as a Pine grower, but rarely or never did the fruiting Pines in a low house like No. 2, have 90° from artificial heat in winter. A rise from sun heat was a different affair. We certainly would not have kept such a house, as section No. 3, at 90°, in such weather as we have lately had; but in very cold nights we would have been satisfied with 20° or even 30° less. We should hesitate to give any plants 90° for a continuance, or as a standard, in dark winter weather.

6. With these hints and modifications kept in mind, we have no doubt that No. 1 and No. 3 altered will answer well, especially where coals are cheap and good. On the other hand, we think that old-fashioned No. 2 is rather summarily dismissed, especially on the question of cost. We presume this refers to the eight-foot wall at the back, though that might be lower. First cost is not always a loss. In cold districts, and where fuel from carriage is expensive, such a house would be decidedly the most economical. If

partly sunk—say 2 feet under the ground level, it would be less exposed to the wind. If on high ground in these circumstances we would even dispense with the hip roof at the back, and have all the glass facing the south, or have only a short hip for gaining room, and lessening the height of the wall. The front path shown is very useful, but with double sashes for the width, that path might be dispensed with, and all from the pathway to the front wall turned into a bed, and the front rows be looked to from the outside. This, with a 3½-feet pathway, would increase the amount of available space in the bed by fully 3 feet, making it 10 instead of 7. Such a house, especially if sunk a little, could be more easily kept at a moist heat when necessary, than a house glass on all sides. In such a low house without a front path, so far as we recollect, very fine Pines were grown at Trentham. The question as to first cost in such houses is of less importance than the advantage of abundant light from glass on all sides, and as that will be affected by the after-consumption and cost of fuel.—R. F.]

### WHAT IS THE BEST POSITION FOR FORCING STRAWBERRIES?

THE excellent and practical notes on this subject, at page 189, by your esteemed correspondent Mr. Ingram induce me to offer a few additional observations deduced from my own experience. Mr. Ingram endorses my views generally on forcing Strawberries, and agrees with me as to the essentials for their successful growth—viz., light or close proximity to the glass, and ample ventilation—air above, below, and all round the plants—to which Mr. Ingram adds, “the roots should always be kept cool and moist.”

Though identical in our views on the subject, we differ as to the best mode of securing these conditions. I, like Mr. Ingram, was led to the idea of having shelves fixed on the roofs of houses for forcing Strawberries from “finding that Strawberries always succeeded on shelves placed in the front of lean-to houses close to where the roof-lights rested on the front supporting plate, and where a little air constantly entered; at the same time the pot was shaded from the sun by the thickness of the plate.” This was one reason, but another very forcible one was that plants on a back shelf, where they received more light, a little air constantly entering, and the pots receiving a little warmth from the sun, were found to do better than those on the front shelf from December to March, when the objections raised by Mr. Ingram as to the sun’s rays acting on the pots and destroying or injuring the roots came into force and reversed the case, the plants on the front shelf being the best after February.

Acting on experience, and there being a deficiency of accommodation for Strawberry plants, I was under the necessity of furnishing a house with shelves suspended like the front shelves from the roof. An early vinery being then empty and awaiting the planting of the Vines in spring, the Strawberries were placed on the shelves in December, and the result was a crop of Black Prince Strawberries in March. In that month the Vines were planted, and the shelves re-occupied with Strawberries. These did not afford so good a crop as the first, though the advanced season was more in their favour. Mr. Ingram very appropriately describes the cause—“the scorching effects of the sun in the bright drying weather of March” and April had done the mischief. The shelves answering so well for the first crop, more were obtained and fixed on the roof of a span-roofed house, having the ends due north and south, and the plants in this afforded a good crop. The only reason that could be assigned was, that the sun’s rays did not heat the pots so much as in the lean-to, they not receiving the direct mid-day sun, the foliage affording the pots a slight shade, and in the afternoon or morning the sun was not so powerful as to injure the plants.

Deciding according to the evidence in these cases the plants can neither have too much light nor too sunny a situation from December to March, a lean-to being then the best; but after February they can have too sunny a position, unless prompt measures be taken to protect the pots, which being done, too much light cannot be given. A span-roofed house is then the best.

The shelves being moveable, and capable of being fixed in any house not filled with its regular occupants, they can be put up in any house securing the conditions which, according to the season of the year, are best suited for the plants; but if there be no greater objection to them than that of the exposure of the pots to the drying and heating effects of the sun, that difficulty is easily surmounted by having a quarter-inch board nailed on the side of the shelves sufficiently high to protect them. I have found this answer the same purpose as the front supporting plate, protecting the pots from the sun, and keeping them cool and moist, at the same time preventing the drying influences of the increased current of air necessary to keep down the temperature of the house.

I do not think there was any, if much, difference between the plants on the shelves in the centre of the house and those on the shelves close to where fresh air was admitted, the produce being equally good on all, though those on the shelves near the openings did not, perhaps, afford the same quantity and quality of fruit that they would have done had the necessity for giving air been less. That such was the case is very likely, for I found that two shelves placed under the

apex of a span-roofed house did not yield one-half the fruit produced on two shelves placed along the sides by the front supporting plates, where the fresh air entered the house, there being no ventilation at the top, which is the case with many orchard-houses, and is, I think, a mistake; for what is the good of ventilation if foul air be not displaced by fresh? I think the Strawberry-house at Enville, figured at page 354 of Vol. VII., open to this objection; though the roof is only a half-span, that part at top formed by the back lights must constantly be surcharged with the impurities of the house carried there by the ascending heat, for which there is no escape. The span-roofed house above alluded to having been altered so that fresh air was admitted or foul air let out, after that the plants were better there than on the side shelves.

If a house could be exclusively devoted to the forcing of Strawberries it might be desirable to have a stage as in the house at Enville, the room being employed for forwarding plants for flowering in winter; but it is open to the objections raised by Mr. Ingram, and unless a house of the kind were unoccupied or could be spared it would not be advisable to erect such for forcing Strawberries, for whilst building or constructing a Strawberry-house it would be as well to have one calculated to meet all the demands of the plants. The requirements in forcing Strawberries are close proximity to the glass, without being so near as to scorch them, a little air at all times, and a cool moist situation. These conditions are secured in all their integrity in none of the usual structures found in gardens, and cannot be unless a house is constructed on purpose, which is what I believe Mr. Ingram has done, and found to answer perfectly, adding another benefit from a family that has done much for horticulture.—G. ABBEY.

### DEVONIENSIS ROSE VERSUS CLIMBING DEVONIENSIS.

PERMIT me to say a few more words on our old favourite Rose. Mr. Curtis still thinks this is a distinct variety from the old one; he says during his rambles he met with it in several places. Can Mr. Curtis bring proof that the plants he saw were planted previous to 1858? if so, from whom were they obtained? I believe all the climbing ones have been obtained from plants sent out by me in 1858. I am only surprised that Mr. Curtis should want the public to believe that his is distinct. If his variety that he says he so improved upon is distinct, why should he have written to me some few months since requesting to be supplied with 1000 plants? If Mr. Curtis in his rambles will kindly pay me a visit I will show him the parent plant, which is scarcely 18 inches high, but the offspring are growing as wild as any of the Ayrshire Roses in the heart of this city.—SAMUEL PAVITT, *Rose Cottage, Bathwick, Bath.*

### KEEPING FOR A YEAR RANUNCULUS AND ANEMONE TUBERS UNPLANTED.

I was spending the winter at Naples six or seven years ago, when I became acquainted with the gardener at the Royal Palace of Capo-di-Monte. At the time of which I write there were some Ranunculuses coming into bloom, and the size of the flowers surprised me, they being very much larger than any I had ever seen at home. I was informed by the gardener, that to obtain large flowers the roots should be kept dry for a whole year before being planted, that, in fact, they should be planted only in alternate years. On returning home I reported this to my own gardener, who, with evident pity for my ignorance, told me that if kept dry for so long they would not start at all when planted.

Two years later I was at Rome, and in making my way from the church of S. Pietro in Montorio, to the Colosseum, I came across a nursery garden, in which there was a fine collection of my old Italian acquaintances, the giant Ranunculus. On a second visit, I found the owner, and immediately questioned him about this system of resting the roots. The nurseryman told me that he was a native of Hamburg, and had been brought to Rome to take charge of some noble’s villa. In his own country, Ranunculus-growing

was a speciality he was well acquainted with, and when he first came to Rome he could not believe in the success of a system under which the roots were so long kept dry. He had been obliged, however, to acknowledge himself wrong, and he assured me as a fact, that even in the dry climate of Italy the roots were not damaged by the year's rest, and that when so rested they produced larger flowers than when planted every year. I have an old book translated from the Dutch, and published in London in 1711, entitled "The Dutch Gardener," by Henry Van Oosten. In it I find it recommended to keep Anemone plants a year without planting when you wish to obtain seed; but it is not said that this makes any difference in the size of the flower. Among your readers and correspondents there may, perhaps, be some who have tried the system of giving a long rest to Ranunculus and Anemone tubers. If such there be, a communication of their success in growing their plants, would, I doubt not, to many of your readers, be as interesting as it would be to—MONTICOLA.

### SPRING LONGINGS.

SHALL I be trespassing? May I be permitted to shift my attentions to the gardening side of "Our Journal?" Well, our good friend, "WILTSHIRE RECTOR," sets me the example. Why, should I not? Living in and loving intensely the country, of course, I care a little for gardening too; and all, I expect, who live in the country long for spring! When Nature is clothed in her gay attire we rejoice, and though some of us may revel in snow, yet our delightful season is certainly not winter. I presume, then, that almost every lover of the country sympathises with your valued correspondent on that score. I will plead guilty to ardent longing, almost like that of the Swiss, when banished from his beloved country. Yet we are not all alike. A few days back I met an old keeper, who is very fond of and a capital hand at gardening. I began sympathisingly shrugging my shoulders at the frost, and intimating my extreme contempt for the much vaunted old-fashioned winter. His quick reply was, "It's beautiful weather, when it's gone we shall have everything in its right place." Well, "WILTSHIRE RECTOR" and his brother and sister spring-longers, may take what comfort they can from the old keeper's words; but I cannot help feeling, that getting to the right place is awfu' cauld wark.

Ugh! it was bitter again this morning, warm in the sunshine; but just put your nose beyond that cottage, Oh! isn't it delightfully cutting, quite refreshing, that sharp north-easter, which is keeping us all in "the right place." [This was written some days ago.] I thought of my Hepaticas, Primroses, and early chickens, and felt for them all, especially the latter. Talking of Primroses, I have a lot of roots that never see the sun till late in the afternoon. They have been picked by my in-door chickens out of the hedges; they are the most kindly roots, they generally commence to throw up blooms late in the autumn, and they keep on in straggling flower through the winter—now apparently the very life crushed out of them by the frost; now inches deep in snow; and then, again, erect, most pleasant to the eye, and, even in spite of the north-easters, harbingers whispering of spring. Yet winter has its charms. I do not know that a snowstorm has, at least not to myself; there is no guarding against the flakes, driven under your throat now, the hand lifted to move the same and there are two or three flakes down your neck. It is just the same in our outhouses, any cracks and in drives the snow; but, after it is down and whilst it maintains its pristine whiteness, it has beauties peculiar to itself, and our friend, "WILTSHIRE RECTOR," has depicted his beautiful neighbourhood in its wintry dress; it differed somewhat from mine, hence my letter. "WILTSHIRE RECTOR" tells us of poets who described in vivid language scenes they never saw. That may be easy and comes natural to them. My difficulty is far greater—viz., to describe what I did see, that I will endeavour to do, but I shall do scant justice to the scene.

On "WILTSHIRE RECTOR'S" penny-reading night, I suppose, it thawed here; the increased temperature melted all the snow that remained on the branches, soon it rained, freezing as it fell. Before morning the wind rose to a gale,

and those who lived near woods or plantations tell me the cracking and snapping of large branches was terrible, and certainly the havoc was somewhat unusual. Nearly the first object that caught my eye was the top of a Fir tree from the neighbouring plantation, 8 or 10 feet snapped clean off, and sent flying some 20 yards. Several brothers shared the same fate; but Elm, Ash, and Beech, all alike suffered; huge limbs that made respectable trees were laid low, others hanging perilously aloft. All our trees were covered thickly with clear ice nearly half an inch thick. This not only added to the weight, but appeared to render the branches more brittle; they would not bend, and so they broke when the wind rose. The swaying of the branches was attended by a continual crackling sound, broken ever and anon by the crashing of some huge limb.

Of all the trees that I have noticed the Beech and Birch have suffered most severely. It is quite the exception that proves the rule, to see one of the latter that has escaped scatheless. I have marked fully a hundred Weeping Birch trees, many are irretrievably ruined. I have seen one of fully 6 inches in diameter of trunk, with the head twisted off as by some giant's hand, others, where the trunk divided into two branches, split down the stem to the ground. What wonder then, if these larger specimens felt the force of the ice and gale, that my kind neighbour's pet, planted some three years ago on her lawn, and which she assured me the nurseryman had warranted to weep when it grew, should have decided on weeping thoroughly, leaving only the stem. Its neighbour, the Cedar, the most perfectly furnished specimen I ever saw, in sympathy with its companion lost several of its branches; whilst close by two sister Larches have scarcely a respectable branch remaining.

I have said that all the branches had a thick coating of ice. This was a glorious sight; every rustle altering the angle at which they caught the light, the ice appeared like myriads of diamonds covering every branch, and when the sun shone how these glories were increased. They reached the acme of splendour when I saw them with the red frosty sun setting behind them, the branches then assumed a roseate hue, and appeared like rubies and opals with the whole sisterhood of precious stones.

Not only on the grand forest trees were these wonderful marks of the Creator's power visible, every tiny branch, every insignificant leaflet, every withered stem of herbage shared in the sparkling adornments, and added their share of lustre to the scene. From my garden-wall I picked the dried stem and seed-vessels of a Wallflower, it was a picture in itself. On close inspection the dried fibres were plainly seen through the coating of clear ice. I pass over the magnificent forms which the snow assumes when driven by the wind through the gaps of the hedgerows, beautiful as they are they may be seen most winters, but not the fairy scenes I have endeavoured to describe. It was well worth seeing, yet my spring longings are so intense, that I care not to see it again, at least, not for longer than an hour, then let the genial southerner dispel this "fabric of a vision." Even will I consent to be pitilessly pelted by the dislodged fragments of ice—peltings which to me have this satisfaction, that the frost is yielding.

"WILTSHIRE RECTOR" and others, with myself, must take courage. I saw this day, our "early" village Horse Chestnut. I hailed with delight the outer gummy coverings of the buds dropping, and the tender pale green peeping out, and rejoiced that "there was a good time coming," although that unkind easterly may succeed in making us "wait a little longer."—Y. B. A. Z.

EFFECT OF GRAFTING THE ELM ON THE OAK.—In your Number of March 21st you have a paper extracted from *The Naturalist* as to the curious effect of grafting the Elm on the Oak, the twigs producing leaves of both these trees intermixed, and the Editors of that publication ask if anything of the same kind has come under the notice of any other person. So long ago as 1818 Mr. Pontey, of Kirkheaton, near Huddersfield, laid out some grounds for me, and planted a great number of variegated shrubs, and amongst other things two trees having Oak leaves and Hornbeam (or Elm) on nearly every twig on the tree. When I left the house ("Craw Trees," Gomersall, near Leeds), ten

years ago they were still flourishing, and I doubt not are so now; and if you wish it, when the season returns, I will send you a few twigs.—E. S., *York*.

### VISITS TO FOREIGN MARKETS.

THE scene presented to the stranger by the market at Genoa, although not so picturesque and attractive as that of Gibraltar, was a fair representative type of the industrial character of the Genoese, for the quality of most of the country productions was first-rate. I say "country" to mark the distinction between the produce of the land and of the sea; for here I may make the remark that I was surprised, in all the Italian ports which I visited, at the paucity and inferiority of the fish. It would be supposed that the splendid bays and coasts of Italy would furnish very superior supplies of fish; but, although I searched the various markets, I could only find small supplies, and those of most inferior quality, of red and grey mullet, sardines, anchovies, ray, bream, and a flat-fish resembling soles, ink-fish or squabs. The best I saw were some immense crawfish, as large as lobsters, at Genoa; but even their nationality was dubious. Oysters, at Naples, were as fine as our smallest natives; but elsewhere they were hardly larger than the cockleshells, of which crustacea there are evident signs at Pompei that the supply of that mollusc was good, and of a large size. The greatest novelty I saw in fish were some very small fish resembling whitebait, but about half the length, and very much smaller in girth. They were exposed for sale in tubs as caught, and also rolled in flour, ready for cooking. Their flavour was delicate, and I should say even more so than the whitebait. They are called "blanquettes;" but I am not sufficiently learned in pisciculture to say whether they are a distinct breed, or merely the young fry of the sardine, or other similar small fish.

Amongst the vegetables, the most prominent were the Walcheren Broccoli, which was immense; the Purple, on the other hand, was poor. Parsnips, early Turnips, Salsafy, Lettuce, well-blanching Endive, Water Cress, and Leeks, were all good, and well grown. The Radishes were immense, and exceedingly tender and juicy. There were a few Yams, but not of good quality, new Potatoes fair, and Peas very inferior; the blanched tops of the Globe Artichokes, and also Fennel, were on sale. Celery was abundant, but evidently only for culinary purposes, not for salad; for it had all been grown without having been earthed-up, or any attempt made at blanching.

Amongst the fruits Oranges, of course, were the principal in season, and, on the whole, the quality disappointed me; but I was astonished at the very superior quality of the Apples; they were both fine and very good. There were several kinds, but the best resembled the well-known American Newtown Pippin. It had all the crispness of the American fruit, but also more juice, and a slight pear flavour. I could not obtain the local name of this Apple, but venture to recommend it to the attention of some of your pomological friends. I also found the Pine cones on sale, roasted like Chestnuts, at the corners of the streets, and pronounced the kernels or pips very good when eaten hot. Chestnuts were fine and abundant, and were also offered for culinary purposes, shelled, dried, and in barrels; Tomatoes, dried, and hung on strings; kept Grapes were poor in quality, Pears also very indifferent, and, we thought, from a foreign source.

The poultry were exceedingly good; it would not be possible to find better-fed and better-flavoured turkeys in England than those partaken of at Genoa. Other poultry were also good, but the ducks and geese were few in number, and small.

On going into the country I was much gratified at seeing the careful and industrious manner in which the Genoese were cultivating every available bit of land. During my ride I did not see one spot worth cultivating idle, even up to the tops of the hills, and the peasantry appeared thoroughly to understand the benefits of deep trenching, and to make fair progress in their work with a digging tool which would both an English gardener to use. They also appear to use a good deal of the fine shingle, from the seashore, for manure.

At various parts of the city were vendors of bouquets, and I was told that Genoa has a continental reputation for their beauty and the skill displayed in their construction. This was borne out by what I saw; for, on passing up the Strada Nuovo, a large bouquet was being packed in a most appropriate case for a long journey. This bouquet measured exactly 30 inches in diameter, and was composed of a centre of seven white Camellias bedded in sweet Violets; around this were eight rings of pink and pink-and-white (bicolor) Camellias, bedded in dark Pansies; these were surrounded with a belt composed of Ageratum, the flowers of a small Narcissus, sweet Violets, and single Camellias, with a fringe round all of Mignonette, the bed being formed of *Erica mediterranea*. The large circular box in which this was packed had a hole in it, through which the handle of this monster bouquet projected, and by which it was so secured that nothing could touch the flowers inside. I had the opportunity of observing that this bouquet was not an exceptional one; for in several of the houses which I visited there were others equally large and beautifully constructed.

Since writing the above I have visited Leghorn, Pisa, Florence, and Naples, and find such a sameness in the markets that the foregoing description of the things at market will apply to all, the only extra at Naples being the Lupin, which appears to be largely cultivated both for use as fodder and for the seeds. What I thought most worthy of note was the great scarcity of birds of all kinds, both small and great (they really appear to be extinct; even in the towns it is not possible to find a sparrow in any of the streets), the extraordinary fertility of the soil, and lastly, the heavy crops which were growing all around the Vines, close up to the canes, evidently showing that the Italians do not agree with us in the idea that the ground about the roots of Vines ought not to be cropped.—CÆLEBS.

### WORK FOR THE WEEK.

#### KITCHEN GARDEN.

NEVER wait for weeds; take care not to tread on any ground after it is surface-stirred. Beans, make another sowing to succeed those sown in the end of last month. Broccoli, if a sowing has not yet been made of the various winter and spring varieties it should be done without delay. Brussels Sprouts, make a good sowing for winter use. Cabbages, a sowing of any approved sort should now be made to produce plants for winter and spring use. As autumn-sown plants are very scarce, the spring sowing should be forwarded as much as possible by pricking out the plants on a warm border, and watering them when requisite. Cauliflowers, the seed may now be sown in trenches where the plants are to remain. The trenches should be about 4 feet apart, and a few seeds dropped in at intervals of 18 or 20 inches. Cauliflowers, prick-out the young seedlings on a warm border, earth-up those that have stood the winter beneath hand-glasses. Cucumbers, keep the shoots regulated, as on this their fruitfulness in a great measure depends; seed should be now sown to produce plants for ridges. Mushrooms, in making beds to produce through the summer a portion of loam should be mixed with the dung, this will give greater solidity to the bed, which will in consequence produce more fleshy Mushrooms. Marigolds should now be sown where they are required for kitchen purposes. Nasturtiums, sow some seed at the foot of a fence where the plants can do no injury by their rapid growth. Potatoes, water and earth-up those in frames. If the main crops are not yet in lose no time in planting them. Spinach, sow a small quantity of Round-leaved, thin-out the early-sown to 6 inches apart. Savoy, another sowing may be made for a late crop. Turnips, make another sowing to succeed those sown in the middle of last month. The present fine weather is favourable for putting in crops where the soil is of a stiff nature, and it will generally be found that by waiting till the ground is in good tilth the crops are equally early and far superior to those sown last month when the soil was cold and wet. As the heads of Broccoli are cut remove the stumps, as they only harbour slugs and vermin.

#### FRUIT GARDEN.

Growth is slow this spring, but the disbudding of Peaches and Nectarines will soon require attention. First remove

a portion of the superfluous shoots, and in a week or ten days go over them and regulate them finally. The superfluous shoots of Apricots must also be removed, and the remainder carefully examined for the green caterpillar, which not only injures them but also eats holes in the young fruit, thereby causing it to gum, grow deformed, and fall off before it is stoned.

#### FLOWER GARDEN.

In vacant places patches of showy hardy annuals which usually exist in herbaceous-beds and in the borders of shrubbery, should now be sown. Double Poppies of various colours, Lupins, Sunflowers, African and French Marigolds, Erysimums, Clarkias, Gilias, Collinsias, Silene, and Nemophila, are excellent for that purpose. A sufficient quantity of cuttings and seedlings of half-hardy climbers should now be potted for planting out in May. With such plants as Cobceas, Maurandyas, Lophospermums, Calampelis, Tropaeolum canariense, &c., many bare places on walls and trellises may be covered and made ornamental which would otherwise be unsightly. Look well to recently transplanted trees and shrubs. A sprinkling overhead with the engine on the evenings of fine days will, when the weather shall have become a little warmer, be of more service to large evergreens than overwatering them at the root. See that all recently-planted trees, whether large or small, are well secured against the wind. Now, with April showers and bright and occasionally warm sunshine, we must be in readiness for mowing. Have the turf swept, well rolled, and made thoroughly firm without loss of time, and remember, that if the first mowing is deferred until the grass grow long, it will require much time and labour to bring the turf into a proper state. Also, let the edges of the walks be cut and otherwise put in proper order.

#### GREENHOUSE AND CONSERVATORY.

What with Azaleas, Camellias, bulbs, and a sprinkling of New Holland plants, the conservatory will now be gay with flowers. Let every plant be placed in the most suitable position, and aim at maintaining a pleasing uniformity of arrangement and displaying the colours to the greatest advantage, bearing in mind that no amount of floral display will compensate for bad arrangement. Let climbers, both in pots and borders, have due attention in regard to training, and retain no more shoots than the allotted space will afford room for. Pay particular attention to the Liliams now in pots, by giving them a liberal supply of water and by neatly staking them. Let Fuchsias, which are so useful for summer and autumn flowering in the conservatory, be repotted as required in rich compost, watering occasionally with liquid manure. The leading shoots of Epacrises, Chorozemas, Correas, Heaths, together with as many choice plants as produce the best effect in a bushy state, should be frequently pinched or stopped in order to form good specimens; also, those of Calceolarias, Verbenas, and other young stock intended either for decorating the flower-beds or for succession in pots. Pick off decaying flowers and leaves directly they make their appearance, and endeavour to replace the plants in the conservatory with others as soon as they begin to become shabby. Sprinkle the surface of the beds frequently so as to assist in keeping the atmosphere moist, and also see that the under soil is kept in a uniformly moist state. Watch for insects and attack them as soon as perceived, which is the only way of preventing their doing mischief.

#### STOVE.

Proceed with the repotting of such plants as require it, and give all necessary attention to those in active growth. If any plants require propagation, seize an early opportunity. Keep a moist atmosphere with a sweet and regular circulation of air, using abundance of water about floors, and syringing frequently air plants or others suspended. Shut up with a solar heat, if possible, of 80° towards three or four o'clock. As spring-flowering plants and for cutting we know of none more useful than Begonias. Now will be a good time for commencing with a stock for next season's display. As they go out of bloom allow them a short rest in rather a dry house, when they may be partially disrooted and repotted, pruning-in any straggling shoots. Keep them close and syringe frequently, when they will soon commence growing. Abundance of light and a tolerable share of pot-room are necessary to insure fine plants.

#### PITS AND FRAMES.

Attend carefully to the stock of bedding plants, and get rooted cuttings potted-off as soon as they are in a fit state, and encourage them with gentle bottom heat. Calceolarias, if well established, may be planted out in a turf-pit in poor sandy soil, where they can be protected from frost or cold winds.—W. KEANE.

### DOINGS OF THE LAST WEEK.

#### KITCHEN GARDEN.

THE anticipated genial change in the weather has made us busy. Forked over the ground among young Cabbage plants and Broccoli, and gave the latter some drainings from the farmyard, making sure that it was not too strong. Turned out Peas, Beans, &c., in turves from between rows of Potatoes, under protection, approaching maturity. Forked the ground and earthed-up Potatoes where wanted. Those grown in pots have turned out useful. Put a few branches among the Peas and Broad Beans for a few days, and then turned them out, dividing a turf some 1 foot in length, into three pieces, and in the case of Peas, staked as the work proceeded, and put a few laurel twigs near the bottom of the rows, to act as temporary protection. *Early Peas* are such an object that a little extra trouble must not be grumbled at. The twigs and the staking keep the birds, too, at a distance. A neighbouring friend has told us that his Peas have not moved a bit, except downwards, for the last month, the sparrows having a feast on the young shoots every morning. A string is of little use after staking, but the birds seem to have a dislike to the green twigs of the laurel. The staking as the planting goes on leaves the ground sweet, open, and porous. How different when the ground is all trampled and trodden. Last year our early Peas were wonderful for strength and produce. Against our usual rule, we have put these transplanted ones in the same place this year, as we have only a very small piece of south border. Potted-off and sowed more Dwarf Kidney Beans. Now is a good time to sow about half a dozen Beans in a five-inch pot, and place them in moderate heat, and when the plants are stopped and stubby, turn them out under protection in May. Thinned out Cauliflowers from hand-lights, leaving four and five to each. The thinnings were planted in rich ground, the plants left under the hand-lights being well watered and dressed with rich compost, and the glasses raised by placing earth on the part where they stand, leaving a basin in the middle. As they become stronger they will be bent outside of the glass to give them room, and the glass itself will be elevated on bricks, so as to keep the stems warm. Those in pots have yielded some nice little heads. Cucumbers in frames have had some banking-up given to the frames. Sowed more Onions and a good piece of Carrots. Hoed among Onions and other winter crops, proceeded with planting some more Potatoes, and prepared for planting Jerusalem Artichokes, Sea-kale, and Asparagus, sowing the two last, and a few Winter Greens, Turnips, and Radishes, the last two under protection and in the open air, the latter to be defended with branches. Carrots and Turnips that have stood the winter, however young, are now apt to be hard and stringy.

#### FRUIT GARDEN.

Very much the same as last week. Proceeded with outdoor pruning, even if we could not follow up with nailing and tying, as all such work, and out-door work in general, is behind this season, owing to the weather having been so unsuitable. A few fine days, however, will permit of many things being done.

#### ORNAMENTAL GARDEN.

Very much the same as last week. Pruned Roses and other shrubs as we could get at them. Rolled lawn after sweeping. The winds have brought lots of tree leaves from a distance which gives a littery appearance, and all dead twigs have been pretty well shaken out of the trees. Looked after fresh-planted trees and shrubs to see if they were firm, and the stakes all right. If we have much bright sun syringing, or a little hay scattered, or fresh-planted evergreens, will lessen the evaporation. We once moved a number of tall-stemmed Oaks from a thick plantation to plant in a park, and part we left to take their chance, and round

the boles and the principal branches of the rest we wrapped strawbands, and gave them several dashes overhead with the garden engine during a hot spring. Those left alone had a hard time of it, the cold and then the dry atmosphere were too much for them. The ropes not only lessened evaporation, but gave the plants something of the protection they had received in the thick plantation. For want of such little attention at first, we have known Oaks carefully lifted from a thick plantation, and carefully planted in bleak exposed places, that were hardly perceptibly larger a dozen of years after they were planted. If the ground had been prepared for them, and small Oaks, say 3 feet in height, planted with some Larches or other things as nurses, the young plants, if the nurses had been gradually removed, would in less time have been a-head of the transplanted ones. The want of success in transplanting is very often owing to the want of warmth.

Roses should be gently smoked if the least fly appears on those in-doors. If done before the bud swells much it will not be wanted afterwards. Two or three gentle smokings are better than one strong one, as too much will be apt to injure the tender leaves. If the foliage or buds are hurt by beetles they must be sought for at night. Pinks and Carnations showing bloom should also be smoked before the buds open. Those to be planted out of doors and now in pits and frames should also be well cleaned before turning them out. If only a few are touched, a finger and thumb run along the shoots will often do all that is necessary, if the shoots are washed afterwards with clean water. The secret of preventing fly and other insects consists in keeping the plants cool instead of hot, and even then to do well they must be pretty hot in sunshine, keeping them in a comparatively low temperature at night. A great object would be gained could people be convinced that hosts of insects will attack plants when enervated by heat that will never touch them when they are kept comparatively cool. A difference of from 5° to 10° of night temperature will frequently make all the difference between clean and healthy, and sickly and insect-covered plants of Cinerarias, Calceolarias, Pelargoniums, &c. If it should be necessary to smoke the latter and syringe them afterwards, the plants should be shaded until the foliage is dry.

Climbers in the conservatory, greenhouse, and stove should now be regulated and pruned. The best plan generally is to fasten the main stems and allow the young flowering shoots to dangle pretty well at pleasure. No system of training will be so effectual and graceful.

Cockscombs to be fine must have a nice sweet bottom heat until the comb is nearly its full size. Early Balsams should have plenty of air and a lower temperature than Cockscombs. Now is a good time to sow Balsams, either for planting in the flower garden in June or for cultivating in pots. After the end of May a cold pit or frame is the best place for them; and in their young state the plants will be better if never receiving more than 55° from artificial heat, with a rise of 20° from sun-heat after a little air has been given early.

Stove plants for winter-flowering, as *Justicias*, *Eranthemums*, *Goldfussias*, *Euphorbias*, *Poinsettias*, *Begonias*, &c., may now be repotted; and cuttings of all these inserted in a hotbed now will make nice flowering plants by the autumn. The *Begonia fuchsioides* may be struck now; and quickly grown in summer, and a little stinted of water in the autumn, it will bloom nicely all the winter. Old, tall, or long plants make also nice rafter plants if they are now well cut in to the older wood—that is, the winter-flowering shoots cut back to a couple of buds or so, and then fresh earth given to the roots after the plants are breaking afresh.

Sowed lots of tender annuals, as *Cannas* and *Ricinus*, and potted a lot of *Cannas* that were kept cool under a stage all the winter. In our cold place *Cannas* do so little as respects robust vigour out of doors, even when encouraged with some hot dung below them, that we are pretty well resolved to use their fine foliage chiefly for giving a marked feature in the conservatory. One thing against them out of doors with us last season was the great dearth of water. The year before they did middling, but not so well as they do farther south, and even much farther north in sheltered warm places. The finest dwarf Balsams we ever saw out of doors were in the north of Scotland. Considering the

vigour and robustness they attain in most parts of England when planted out, it is singular that rows of such fine plants are not more frequently met with. Except in cool, open, airy houses it is scarcely possible to obtain such fine plants in pots as may be grown in rich compost out of doors, when planted out about the end of May. We have seen many a sickly shrivelled Balsam standing on the outside sill of a parlour window that would have shown a lively sense of gratitude for favours received if turned out into the adjoining border.

Gave more room, and thinned the foliage a little of the most forward Pelargoniums, which are now standing in the late vinery, where they obtain plenty of light and air, and no artificial heat except in very cold nights. We have at present no time to train them much. A second lot should have any very strong shoots stopped, so as to equalise the growth. Potted a lot of plants struck last autumn. At Latimers and other places we then saw fine pots of *Ipomoeas*, *Convolvulus*, &c., in the conservatory. These should now be sown in pots, and thinned out to four plants or so. They do not do so well transplanted. Even the Canary *Nasturtium* does best either sown where it is to grow, or sown in pots and then planted out. After it is from 3 to 6 inches in height it does not transplant so well.

Sowed a good lot of half-hardy annuals, as *Marigolds*, *Asters*, &c., in a bed, to be protected by a cloth, branches, &c. We had a lot of litter that had been used for covering, which we hope we shall not need now. This formed the bottom and sides of our bed, and some 12 inches of very warm tree leaves the upper portion, with 2 inches of rotten leaves and 2½ inches of fine soil to sow in. Such beds are more hardy than boxes or pots, and require much less attention afterwards.

Commenced in earnest to thin our glass houses of bedding plants, by turning out lots of *Scarlet Geraniums*, &c., under protection, just placing a little rough warm leaf mould over the roots in the trench. Thus treated they generally lift well. Turned out from a hotbed, a lot of variegated ones that had been planted on pieces of turf, the roots already hanging round the sides of the turf. This turning out will check them a little, and prevent the roots running from home, and they will scarcely want above one or two waterings until they are transferred to the beds. A lot of young plants of *Golden Chain* are doing well under this mode of treatment. Now as to protecting material. We shall use almost every conceivable thing—frigi domo, calico, straw hurdles, wattled hurdles, matting, &c. But for the expense we prefer calico. For an earth-pit 5 feet wide, procure calico about that width, or an inch or so more; have the calico in—say 30-foot lengths, and fastened to a pole at each end, with some seven strings fastened back and front, with which to keep the cloth tight, by looping over little sticks when it is rolled over the plants, after placing some stakes across the bed to keep the cloth from the plants. In many cases we have turned out plants under such a cover in the beginning of April, and they scarcely wanted any more care, except a little extra protection in a frosty night, until they were exposed some days before final planting out. Frigi domo does very well, but it does not let the nice subdued light reach the plants in the same way.—R. F.

#### TRADE CATALOGUES RECEIVED.

E. G. Cooke, 8, Stewardston Road, West, Approach Road, Victoria Park, London.—*Catalogue of New and Choice Geraniums, Fuchsias, Dahlias, Verbenas, Chrysanthemums, and other Bedding Plants.*

T. Townsend, St. Mary's Nursery, Hornsey.—*Catalogue of Greenhouse and Hardy Plants, Shrubs, Trees, &c.*

#### COVENT GARDEN MARKET.—APRIL 8.

Notwithstanding the mildness of the weather supplies have scarcely improved, and everything remains much the same as last week.

TO CORRESPONDENTS.

\*\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

N.B.—Many questions must remain unanswered until next week.

**CUCUMBER-GROWING (Amateur Gardener).**—Your best plan will be to obtain sufficient hot dung to form a bed 1 foot wider than the frame, and about a yard in height. Shake the dung thoroughly out and mix it, and beat down with a fork; it will also be all the better if turned over once or twice to allow the rank steam to escape. It will then afford a milder and more lasting heat, besides not generating so rank a steam as when made up of fresh dung. The bed having been made, place the frame upon it, and put on the lights. In about a week the heat will have risen in the bed; then, taking off the lights, level the surface of the bed, and if the heat is not too violent (this you may ascertain by thrusting a trial stick into the bed, and if you can hold the end tightly in the hand without a sensation of burning the heat is not too great), put under the centre of each light half a barrowful of loamy soil—that from rotted turves a year old is the best—in the form of a cone with a flattened top. An inch or so of soil placed over the surface will, to a great extent, keep down the rank steam. This done put on the lights, and in a few days you may plant in the hills, putting one plant under the centre of each light, or two under each if the lights are 6 or 7 feet long, and of corresponding width. Water after planting, and regularly afterwards according to the condition of the soil. Always use water which has been exposed to the air, and of the same temperature as the air of the frame. Admit air on all favourable opportunities, opening early and closing early. The temperature by night may be from 60° to 65°, giving air at 75°, and closing at 80°. When the roots come through the sides of the hills place more soil over them, and about three weeks after planting cover the bed with soil sufficient to make a thickness of 9 inches all over the surface. Stop the shoots by pinching-out their points one joint above the fruit, or if none show stop them after they have grown a foot in length, presuming them to have been previously stopped at the second leaf. Do not allow the shoots to become too crowded, but thin them out, always taking out the weak and those that have borne fruit. Water through a rose over the surface on bright days at 4 P.M. This will be required about twice a-week, or in very bright weather every other day, then shut up the frame.

**BOOKS (E. M.).**—The "Cottage Gardeners' Dictionary" may be had at our office for 5s., or free by post for 5s. 8d. The other work, with supplement, costs £1 11s. 6d. Apply to the curator of the gardens. (E. B.).—Henslow's "Rudiments of Botany" is a very good work.

**CHOROZEMA CORDATA OVER-VIGOROUS (W. A. O.).**—Your plant is excessively vigorous, a condition which the leaf mould and planting in a border would have a tendency to induce. So long as the plant continues to grow so vigorously it will not bloom, but if you confine the roots to a part of the border, and keep the soil rather dry in winter, it will bloom all the finer in consequence of being vigorous. It should have a light airy situation. It will not bloom in a shady border.

**FERNS IN CASE MOULDING (R. and E.).**—The cause of the fronds moulding is the atmosphere being too confined. They should have a little air, and the moisture should be wiped off the glass once a-day in the morning, or air may be given to dry it up. The case should be opened a little—half an inch or so at top—so as to allow of a change of atmosphere. In other respects we think your arrangements and management good. Of the Ferns in your list, the Gymnogrammas, Cheilanthes, and Notochloenas are not suitable. They require just the reverse of a close confined atmosphere, though they flourish in one that is moist. The others ought to do well.

**FRAME ON VINERY-BORDER—STRIKING MRS. POLLOCK GERANIUM (Mrs. W.).**—We would plant the Vines inside, but, as you correctly show, make sure that your inside border is rather the highest. The frame or pit will be an advantage every way, provided you keep plants in it that require little water in winter, and are able, if not to remove the glass, to remove the plants in summer, in order that the sun may shine upon the soil. These two matters kept in view, your pit or frame will answer admirably. There is no secret about striking Mrs. Pollock Geranium; if you want a good plant quickly from a cutting you must use a good-sized cutting. Clever gardeners may cut up a young shoot into as many pieces as there are leaves and make a plant of each, just as is frequently done with Verbenas, making two plants from every joint; but were you to try the plan and could not give the requisite attention, most likely you would lose them all. Striking such things as Mrs. Pollock from leaves without a piece of the stem with the leaf, we consider sending amateurs on a wrong scent.

**BIRD'S-NEST FERN FRONDS DECAYING—PRUNING IPOMŒA LEARII (Scrap).**—The probable cause of the fronds not developing is the close stagnant air of your house, and allowing water to stand or drip on them. It is impatient of water on the fronds, and will not do in an excessively moist house. Cease syringing and re-plant the plant, providing good drainage and using the compost rough. Maintain a moist atmosphere by sprinkling the floors, &c. We think the syringing the leaves twice a-day is the cause. *Ipomœa Learii* may be pruned close in the autumn, which is the usual practice, it being necessary to prune them or before growth recommences, in order to have strong bines, and consequently large flowers.

**CUCUMBER LEAVES BLOTCHED (A Constant Reader).**—The Cucumber leaves are spotted and blotched from steam or heated vapour. Most likely there had been a large amount of vapour in the house, which had become condensed on the leaves, and the sun had caught them next day before air was given to let off the hot vapour and dry the leaves. The rest of the young foliage will most likely come all right if the necessary precautions be attended to.

**PLANTING HONEYSUCKLES (M. A.).**—The best flowering and most hardy of the Honeysuckles is the Woodbine (*Caprifolium periclymenum*). *C. Brownii* and *Youngii*, varieties of the Scarlet Trumpet Honeysuckle, are fine and free blooming; and so are *C. odoratissimum*, *Shepherdii*, and *flexuosum*. They are best planted in autumn or early spring, but they may be removed now if taken up with a good ball and well watered at planting, and during dry weather until established.

**PROPAGATING DOUBLE PRIMULAS (Idem).**—These are propagated by taking off the offsets with a heel, or dividing the plants with a sharp knife, trimming off the lowest leaves, and inserting in a compost of sandy peat two-thirds, and turfy loam and silver sand in equal parts one-third. Let the base of the cutting or rootless divisions rest on and be surrounded with silver sand. They are best inserted singly in small pots. The soil should be kept constantly moist, but not very wet, otherwise they will damp off; give slight shade and a moist atmosphere, but do not syringe overhead, and plunge the pots in a bottom heat of 75°. The compost we grow them in after the plants become established is equal parts peat, leaf mould, and loam from rotted turves or turfy loam, with a free admixture of silver sand, affording free drainage.

**CUTTING-IN PORTUGAL LAURELS—PLANTING YEW, AND OTHER EVER-GREENS (M. E.).**—Our remarks about cutting-in variegated Holly apply to all evergreen shrubs, but especially to Hollies, Yews, and Laurels. You may cut the Portugal Laurel in from the middle of this to the first or second week in next month. If the growths are only irregular you may, by shortening those which are irregular, and retaining the smaller shoots, leave the tree quite feathery; but if very irregular shorten all, cutting the strongest shoots closer in than those which are weak, still leaving all much of the same length in order to secure a well-shapen tree. It is not too late to plant Yews, Laurels, and evergreens, if they be removed with a certain amount of soil attached to the roots. We have less deaths by transplanting at this season than in September and October.

**FLOWER-GARDEN PLAN (C. J. Cricklenood).**—For the style you propose we think your arrangement will do very well. Scarlet and purple Verbenas would look well in 4.

**MUSHROOM SPAWN FAILING (J. E.).**—We have examined carefully the pieces of spawn sent. No. 1 we should think has perished from damp. It seemed a mass of worms and larvæ of different insects. Whether such a state of things would proceed from doing the horse we cannot say. No. 2 seems perished, most likely from a little over-heat, but of that you are the best judge. A few hours extra heat will do it. No. 3 is nearly gone, but there are still some good spore threads, and if that was inserted on the 3rd of February we would not yet despair. No. 4 is very fair spawn—looks as if the bed was damp enough, but still, though the threads are a little too far gone in some places, the spawn in such a state ought to produce heavily. Certainly we would trust to such spawn, but if at all damp, or the bed damp, wrap it in dry litter. If the piece sent has been taken from the bed we would say let the bed alone. No. 5 is very fair—not first-rate, nor so good as No. 4, but it is such as we would use with confidence, using it freely—that is, more of it. We have no doubt the bed in the shed will do well; if doubtful you had better have a little fresh spawn. We should use 4 and 5.

**HYACINTH CULTURE (Monticola).**—You can obtain Mr. William Paul's Lecture on the Hyacinth direct from him. What he has so plainly and systematically stated in his admirable lecture on the propagation and general cultivation of the Hyacinth, both in Holland and in this country, may be fully relied on, and we will not, therefore, refer you to any other work. As we think you will gain all the information you require from it, our answers to your queries will be short. 1st, Yes; the size of the bells may be increased by high cultivation during the year in which the bloom is produced. The spike may also be increased in size and length; but the spike itself, and the number of florets or bells are formed in the bulb during the growth of the previous season. If the bulb were subjected to high cultivation, and received a greater amount of attention, doubt sufficient matter would be stored up in it to enable it to produce three or more spikes of bloom instead of one; but of course the growers of bulbs of this description would be obliged to charge more for them, as such would require more room to grow in, and a greater amount of manure, &c. 2nd and 3rd, See Mr. Paul's Lecture on the Hyacinth, pages 10 and 11. 4th, The only reason we have for thinking that Hyacinths cannot be cultivated so well in this country as they are in Holland, is the same as that quoted by Mr. Paul, page 10—"In the month of June, at which time the bulbs are ripening, the earth-heat appears to me greater than in any soil of which I have had experience in England."

**REBUBING AGAPANTHUS UMBELLATUS (C. M. Major).**—It is too late to rebub your plants now; the proper time for doing it is as soon as they have done flowering. You had better supply them, during the coming summer, with plenty of manure water; they cannot be drenched too much with water during their season of growth. As they are plants that will not bloom well unless their pots are very full of roots, they should not be repotted very often. The plants should be well drenched with water several times before they are potted, so that the balls may be thoroughly soaked through. The roots around the outside of the balls should be disentangled before they are put into their new tubs, or it will be a long time before the roots will work into the fresh soil. Care should also be taken to press the new soil firmly around the ball. If this is not done the water will pass through the new soil, leaving the old ball quite dry. The shift you propose giving them will last them a great number of years.

ROSES IN POTS (*Yorkshire Amateur*).—Twelve good Roses for pots. Anna Alexieff, C. Cœlle de Chabillant, Général Jacqueminot, John Hopper, Jules Margottin, Pauline Lanzeur, Senateur Vaise, Victor Verdier. Bourbon—Catherine Guillot, Souvenir de la Malmaison. Tea—Gloire de Dijon, Souvenir d'un Ami.

NAMES OF FRUIT (*A Constant Reader*).—2, Rymer; 4, Northern Greening; 5, Lewis's Incomparable; 6, Trampington. (*F. D., Pershore*).—1, Not

known, too sweet without crispness. 2, Queen Pippin. 4, Benrre de Rance, from rather late blossoms. 5, Not sent. 6, Not known, a kitchen Apple. NAMES OF PLANTS (*Basil*).—*Albizia lophantha*, often called *Acacia lophantha*. (*J. J., Hants*).—Your plant is the well-known Dog's-tooth Violet, *Erythronium dens-canis*. Surely you cannot have shown it to any intelligent gardener. *John Edwards* must send a better specimen of his *Oxalis* sufficient to show its habit, and in flower.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending April 8th.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THE COLD WEATHER.

(Continued from page 258.)

WHEN all these funny eggs are become chickens and the sun shines upon them, and the earth is teeming with insect life, and part of creation bursts into being to feed another part, and a lot of them are luxuriating in a dust-bath and opening their feathers to the sun, we like to see a fly of some sort pass just over them. Up they jump, away they go, their little necks are stretched "upward and onward," till one catches it. If it be large enough to require the captor to stoop in order to swallow it, the sight of it in his beak makes him the envied of all the others, and although the event is not so disastrous to him as it has been to the fly, he has to suffer the same chase. Very often he goes till his wings droop, his legs drag, and he is obliged to drop his prize, which becomes the prey of another. Or, let the hen give her danger call while they are dusting, see how they start, and mark the clouds of dust they raise. We are fond of watching these things, and childish as they may seem, we dwell on them because they are in reality essential to the well-doing of chickens. They multiply troubles who would improve or teach Nature. When we see artificially-reared chickens, or hear the complaints of those who have undertaken the task—when we see the attic devoted to hens and chickens, the appliances for artificial heat, the floor covered with inches of dust, sand, and gravel, and yet the poor appearance of the chickens—we cannot help contrasting them with the healthy rogues basking on a naked but dry bank, and bearing all the inclemency of January, February, or the most unkind month of March, 1865. Only one thing really torments us, and that is snow. Save us from snow. No scratch for hens or chickens, no grubs, no worms, no insects. The food sinks in deep, and chickens have not the reindeer's gift, of foraging under the snow, or of smelling through it. We like them when they are strong, hearty, and defiant; but often during the tiresome March just gone, we were almost glad that, owing to the scarcity of sitting hens, we had not more chickens—poor little things stepping daintily about, picking some crumbs of choice food, and then listlessly settling down; the head sunk between the shoulders, wings and tail drooping, standing like a Heron watching for fish, and changing their position only, when with a pitiful "peep," the head was put under the wing. What a change came about with the change of wind! Many years ago when smuggling was more thought of, because it was what was called "a hanging matter," an old friend—no, not a friend, an acquaintance—did "a little in that way." He was a fine shrewd fellow, but what with being exchequered, running ashore, and losing cargoes, he left off while yet young with more rheumatism than money. The east wind sent him to bed, but he has often told us that while there, after weeks of confinement, he felt a change of the wind in the night, and his joints softened. We think our chickens did the same; they were joyous

fellows in the morning, while they had been sore grumblers the previous evening. They had been living in a barn, where with our rips we formed a sort of eastern yard, presenting a square inside of open fronts, whilst the backs formed the defence against east winds, torries, rapparees, and everything of the sort. Just as Corny Delany, having nothing but herrings to give his mother, persuaded the good woman it was always Lent; so we, thinking bed the best place for them, kept them much in darkness, persuading the hens it was night. This did well for a time, but the moment the weather changed they burst the bands; they flew over the barriers; they snuffed the sou-wester through the chinks and crevices, and we let them out.

We have them now under a hayrick, along a dry bank under a quickest hedge, and, *horribile dictu*, on the gravelled walks of a kitchen garden. After much experience we are convinced they are good gardeners. They live much among the strawberries; they turn over every leaf, they are continually seeking for grubs and insects, and they do no damage. They are growing fast, and while we watch them daily we say to ourselves, We will make a note of this. Perhaps we shall again next week.

THE WIGTON EXHIBITION OF POULTRY.

THE Committee of the Wigton Poultry Show, by a rigid perseverance and annual increase in the value of their premiums, ensure not only a continuance, but an enlarged amount of local support to their meeting. We have no doubt, however, that the number of entries to the show just closed was somewhat curtailed from the fact of its taking place simultaneously with the one at Accrington, or at least from the latter being held so soon afterwards as on the following days; it was, consequently, impossible for exhibitors to send the same pens of poultry to both. From this cause alone the entries were scarcely numerically equal to those of last season, though the general good quality showed much improvement in the majority of the classes. The weather being most propitious the visitors were numerous, and a love of poultry culture seems fast extending itself throughout the district. As the neighbourhood is very dry, with a gravelly subsoil, none could be more suitable for the raising of young broods, or, in fact, for the maintenance of robust health in the older birds, as every amateur's experience proves that though a damp soil is hopelessly fatal to success, the majority of breeds of poultry will endure without injury even an excessive amount of cold, if the situation is both dry and open. It appears, too, that a very spirited emulation exists between a number of the local breeders around Wigton, and that though truly anxious to excel all rivals the most perfect harmony and goodwill exists on all hands. This is, as it should be, and we are gratified at being able to state this fact, as unfortunately in some neighbourhoods that we could name, the unsuccessful are prone to give way to irritability and severances of friendship, even if fairly beaten.

As might be anticipated a considerable number of those hens or pullets that had commenced early laying were failing a little in condition, and in some instances fast

approaching to broodiness, to which the mildness of the last week may have also contributed.

In the *Game* fowls it was especially so. Perhaps fewer entries of Brown Reds never occurred in proportion to the other varieties of Game than at Wigton. Mr. Fletcher, of Stoneclough, near Manchester, however, exhibited a grand old cock of that colour that secured for its owner a silver cup, as an extra prize offered "for the best Game Cock." The Game cockerel that took the other cup belonged to a resident of Wigton, Mr. J. Robinson, of West Street. He is a good and remarkably true-feathered Black Red, but somewhat smaller than could be wished. It is remarkable that in a large class of Game *Bantams*, not even a single pen of Brown Reds was to be met with. There were, however, some good Greys and a very nice pair of Red Pile *Bantams* exhibited. The Golden-spangled were the best variety of the *Hamburghs*, and the Black *Polish* were excellent. In Sebright *Bantams* the show was a failure; and it seems probable that this somewhat delicate variety does not thrive well so far north; at least, it is rare, indeed, that a good pen is exhibited thereabouts. The prize *Spanish* and the Grey *Dorkings* that took position on the prize list were very perfect, but the remainder of the birds in these classes were indifferent.

Some *Guinea Fowls* exhibited in the class for "Any other variety of poultry" were good, but as discontented and restless as these birds are ever prone to be when subjected to even the slightest constraint.

The Aylesbury breed of *Ducks* do not show to advantage from the district around Wigton, the bills, however pure at the outset, soon attaining a yellow hue in the neighbourhood. It is worth bearing in mind that on some waters nothing will preserve the delicate character of the bills, however great the pains and trouble taken to do so. The Rouen *Ducks* were, however, far better than are usually met with, being both a numerous and generally good class throughout. A singularity of the show at Wigton is the offer of a special set of prizes for "Wild *Ducks*," or rather semi-domesticated Wild *Ducks*, they seeming to be a much valued breed among many of the neighbouring gentry. Even when thus kept their excellence for the table is incontestable. The class for *Ducks* of "Any other variety," produced a good display, the first prize being secured by a pen of Shell *Ducks*, or, as commonly known on some coasts, the "Saint George's *Ducks*," belonging to Mr. T. M. Armstrong, of Aikhead, and they were shown in absolutely faultless condition, nor can we call to mind a single instance in which the excrescence at the base of the upper mandible of the bill was nearly so well developed as in the drake now under notice. Although we have ourselves kept many of them for years past, so perfect an attainment of this intensely rich coral hue at springtime has not taken place; in fact, to many visitors at Wigton it appeared so thoroughly unnatural as to cause doubts of fair play. This we know, however, that in the wild adult male it invariably takes place at this season, but in the domesticated bird of this species such an occurrence is very rare. This beautiful specimen was hatched in confinement, is perfectly tame, and is some four or five years old. In this class were some crossbreds between the Grey Call Duck and the White Call Duck, spotted and very uncommon, and a good pen of birds bred between the common wild Duck and the Grey Calls were also very interesting, and would be very useful for decoys.

A considerable falling-off in the entries for *Pigeons* this year may doubtless be attributed to the extraordinary competition at Wigton last year among the *Pigeons*, the classes throughout being now by far less filled. The competition was nevertheless, though so limited, not at all without a struggle; for superiority the Carriers, Nuns, Spots, Pouters, Turbits, and Barbs were the most conspicuous.

**GAME** (Black-breasted and other Reds).—First, John Brough, Carlisle. Second, D. Tait, Grasmere. Commended, J. Harris, Wigton.

**GAME** (White and Pile).—First, Jos. Brough, Carlisle. Second, John Brough, Carlisle.

**GAME** (Duckwing and other Greys, Blacks, and Blues).—First, Messrs. Easton & Mabon, Jedburgh. Second, Jos. Brough, Carlisle. Commended, John Brough, Carlisle.

**GAME FULLETS** (Any colour).—First, W. D. Dickson, Thornhill, Scotland. Second, R. Tate, Leeds. Highly Commended, M. H. Brisco, Wigton. Commended, J. N. Hodgson, Wigton.

**SPANISH**.—First and Second, J. Wilson, Whitehaven. Commended, J. Harrison, Kendal; E. Fearon, Whitehaven.

**DORKING**.—First, J. Gunson, Whitehaven. Second and Commended, G. Highfield, Blencogo House.

**COCHIN-CHINA** (Any variety).—First and Second, Miss Aglionby, Grasmere.

**HAMBURGH** (Golden-spangled).—First, J. Wilson, Whitehaven. Second, R. Tate, Leeds. Highly Commended, A. K. Wood, Kendal. Commended, J. Dixon, Wigton; J. Wilson.

**HAMBURGH** (Silver-spangled).—First, A. K. Wood, Kendal. Second, R. Tate, Leeds. Commended, Noble, Kendal.

**HAMBURGH** (Gold and Silver-pencilled).—First, J. Harris, Wigton. Second, —Burrow, Longtown. Commended, J. Moore, Wigton.

**ANY OTHER VARIETY**.—First, J. R. Jessop, Hull (Black Polish). Second, R. Tate, Leeds (Black *Hamburghs*). Commended, T. T. Selby, Aspatria (Guinea Fowls).

**GAME BANTAMS** (Black-breasted and other Reds).—First, M. Redhead, Kendal. Second, Miss Aglionby, Grasmere. Highly Commended, J. Wilson, Longtown; J. N. Hodgson, Wigton.

**GAME BANTAMS** (Any other colour).—First and Second, Miss Aglionby, Grasmere.

**BANTAMS** (Any other variety).—Second, J. Wallas, Highmoor. First withheld.

**DUCKS** (Aylesbury).—First, W. Barnes, Wigton. Second, J. Dixon, Wigton.

**DUCKS** (Rouen).—First, G. Hetherington, Curthwaite Station. Second, R. Jones, Whitehaven. Highly Commended, R. Tate, Leeds.

**DUCKS** (Common Wild).—First, A. Robinson, Carlisle. Second, T. Manduell, Aikhead.

**DUCKS** (Any other variety).—First, J. M. Armstrong, Aikhead (Shell Ducks). Second, T. C. Harrison, Hull. Highly Commended, T. T. Selby.

**PIGEONS—Carriers**.—First, H. Yardley, Birmingham. Second, J. C. Taylor, Middlesborough. **Tumblers**.—First, R. Pickering, Carlisle. Second, H. Yardley, Birmingham. **Pouters**.—Prize, E. E. M. Jones, Ashby-de-la-Zouch. **Fantails**.—First, H. Yardley, Birmingham. Second, T. Manduell, Aikhead. **Jacobins**.—First, R. Pickering, Carlisle. Second, —Taylor, Middlesborough. Highly Commended, W. Hastwell, Kendal. **Nuns**.—First, H. Yardley, Birmingham. Second, J. R. Jessop, Hull. Commended, R. Thompson, Kendal. **Barbs**.—First, H. Yardley, Birmingham. Second, —Taylor, Middlesborough. **Turbits**.—First, R. Thompson. Second, R. Pickering. **Owls**.—Prize, H. Yardley, *Trumpeters*.—First, W. Hastwell. Second, E. E. M. Jones. *Any other variety*.—First, H. Yardley. Second, I. P. Cullen, Carlisle. Highly Commended, R. Pickering, Carlisle.

**BEST GAME COCK** (Extra Prize).—First, J. Fletcher, Manchester. Second, W. Boyes, Beverley. Third, —Geldred, Kendal.

**BEST GAME COCKEREL** (Extra Prize).—First, T. Robinson, Wigton. Second, J. Wallas, Highmoor House. Third, Jos. Brough, Carlisle. Highly Commended, J. Barnes, Wigton; T. Robinson, Ulverston.

**BEST GAME COCK** (County Prize).—First and Second, Jos. Brough, Carlisle.

**BEST GAME COCKEREL** (County Prize).—First, J. Wallas, Highmoor. Second, Jos. Brough, Carlisle. Commended, J. Gaddes, Carlisle; P. Hodgson, Penrith.

**BEST DISH OF ONE DOZEN FRY EGGS**.—Prize, J. Wood, Sandwith, near Whitehaven (Cross-bred, Spanish and Game). Highly Commended, Miss Watson, Daleside (Black Spanish); J. Calvert, Warwick Bridge (Black Spanish); E. Fearon, Whitehaven (Black Spanish); —Strong, Drumleaving (Cross-bred); R. Tate, Leeds (Cochin and Spanish). Commended, J. Mitchell, Egremont (Brown Red Game); R. Tate (Cochin and Spanish).

Edward Hewitt, Esq., of Eden Cottage, Sparkbrook, near Birmingham, officiated as Judge.

ECCENTRICITIES IN PIGEONS.

In reply to "WILTSHIRE RECTOR," I do not think his hen *Powter* will be injured by laying four eggs. It seems to me a curious case, and I trust he will be careful to notice if she lays four eggs next time. I once before heard of a hen *Pigeon* that laid four eggs, but in that case the evidence was not satisfactory to me. I would advise no hempseed to be given to her, but she may have old tares or barley with her Indian corn, and she ought to be well supplied with old mortar broken up. I once found two young *Pigeons* dead in one egg.

How curious are some of the actions of *Pigeons*! Some cocks are so attentive to their hens that they cannot spare time to fetch a single stick for the nest; but I have a Red House *Tumbler* cock so indefatigable in building that he is continually at it, and has carried a small truss of straw into his pen.

Some *Pigeons* seem careless of feeding their own young ones, whereas I have a Blue-bearded cock *Tumbler* whose hen was lately lost in a high flight, who has adopted a couple of young ones, which he nurses with great care, and defends with much more zeal than ever he did his own castle.

I have a White Air *Tumbler*, hatched last year, which took it into her head to feed some young ones that laid on the floor by her while she herself was being fed—and this is not the first case I have heard of one young one feeding another. I had last year a young Black House *Tumbler* which, when he first began to be matchable, showed like a hen, paired with an odd cock, and remained as a hen until he tried to be master, when his old mate had to beat him off. This year I have a small Black Mottled Air *Tumbler* which I thought was a hen, so I put it up with an old Black Mottled Air

Tumbler cock; they paired at once: but I now feel sure he has deceived me, for the two, although fast paired, both coo and clap about like cocks. I have a feather-footed Black Mottled Roller hen with eleven flight feathers in each wing, and, what is more strange, I have two hens paired to the same cock, and both sitting in the same nest for the second time.—B. P. BRENT.

### THE ACCRINGTON POULTRY EXHIBITION.

THE Accrington Society held a most successful meeting on the 6th inst. and following day, and the management had undergone a very careful improvement. The influx of visitors was beyond precedent, showing that such exhibitions are as popular as ever. The prize list was a very liberal one, and consequently most of the classes were well filled. To produce local enthusiasm a brass band was procured to precede the Committee and Judges to the showyard, and afterwards to remain for the entertainment of the Company. All the poultry were ranged at the same height, and everything that could be done was done to secure a "fair field and no favour" alike for all competitors.

On entering the Show, the company found the first class to be as good and numerous a selection of first-rate single *Game* cocks as could well be brought together, the competition being supported by a large majority of our best *Game* breeders. A splendid Brown Red belonging to Mr. Statter was the winner of the silver cup, and it is a rare occurrence to meet with so faultless a specimen. The three winners in this close competition were eventually all Brown Reds; the second prize being taken by Sir St. George Gore, Bart., and the third by John Sunderland, Esq., of Coley Hall, Halifax. At the outset the second premium in this class was given to Mr. H. M. Julian, of Beverley, Yorkshire, for a very powerful and unexceptionably good bird in the hand—a Black Red (pen 267). A complaint in writing having been presented to the Committee and Judges, immediately after the Show opened, from several *Game* exhibitors, urging that "the breast was dyed black," a very rigid investigation took place in the presence of the Committee, and resulted in the most complete exposure of as dishonourable a piece of deception as could well be imagined. That the imposition was carried out most cleverly no one could deny, for though, except in an extremely powerful direct light, no difference in shade could be discovered, the various tests applied proved beyond all cavil or dispute, and to the unanimous satisfaction of every one present, that the bird had been purposely tampered with. After a number of tests the artificially-applied black on the breast being removed, it not only dyed anything to which it was applied the same hue, but the breast of the bird itself again assumed its natural colour of a partially Brown Red. It was consequently "disqualified" altogether, the only punishment that by present rules can be enforced, though no doubt the public mind will speedily suggest some more stringent rule should such discreditable practices unfortunately continue. The class for *Game* cocks, locally restricted to four miles round Accrington, was a very tame affair; but the two following *Game* classes for a cock and two hens were headed by extraordinarily perfect birds belonging to Sir St. G. Gore, and Mr. Fletcher of Manchester. We have seen generally far better collections of *Cochins* and *Brahmas* than were here shown, for, excepting the winning pens, the competition was below that of previous years. The Black *Spanish* were good. The *Hamburgs* were undoubtedly quite a leading feature of the Show; and the closest competition for the Silver Cup, given to the best pen of *Hamburgs*, resulted in a pen of entirely perfect Silver-pencilled (Sir St. George Gore's), taking precedence of the Silver-spangled ones (Mr. Beldon's), that have taken many prizes in their own class. It was one of the closest runs in the Show. The *Polands* were very fine. In *Game Bantam* cocks the entry was a liberal one, and Mr. Munn may rest assured his victory is very meritorious, no less than thirteen birds being favourably mentioned in the prize list. *Aylesbury Ducks* showed strongly; and there were exhibited some perfect *Beunos Ayréan*, *Grey Calls*, and *Rouen Ducks*. The *Turkeys* were first-rate ones.

It is no common occurrence to meet with so excellent a collection of *Pigeons* as those constituting the Accrington Show. All these classes were far superior to those of former years, and the premiums, as an inspection of the appended prize list will show, were very broadly shown. The *Pigeons* appeared to be one of the most popular portions of the exhibition, and it was, in fact, a somewhat difficult task for any but determined individuals to

get a near sight of them, so constantly was this division of the Show thronged by visitors.

**GAME COCK** (Any colour).—First and Silver Cup, T. Statter, Stand Hall (Brown Red). Second, Sir St. G. Gore, Bart., Wirksworth. Third, J. Sunderland, Coley Hall, near Halifax. Highly Commended, J. Fletcher, Stonecough, near Manchester (Black Reds); C. Chaloner, Workop; Sir St. G. Gore, Bart. Commended, C. W. Brierley, Middleton. Disqualified, H. M. Julian, Beverley, York (dyed breast).

**GAME COCK** (within four miles of Accrington).—First, T. Barnes, Accrington. Second, Messrs. Baxter & Furness, Accrington. Third, F. M. Hindle, Carr Hall Mill, Haslingden.

**GAME** (Black or Brown Reds).—First, Sir St. G. Gore, Bart., Hopton Hall, Wirksworth, Derbyshire. Second, J. Fletcher, Stonecough. Third, T. Statter, Manchester.

**GAME** (Any other variety).—First, J. Fletcher, Stonecough (Files). Second, H. Snowden, Great Horton, near Bradford (Duckwing). Third, Sir St. G. Gore, Bart.

**DORKING** (Any colour).—First, J. Copley, Eccleston, Prescot. Second, J. White, Northalerton (Grey). Third, D. Parsons, Cueden Hall (Grey). Highly Commended, T. Statter, Stand Hall (Silver Greys); D. Parsons (Grey). Commended, Mrs. M. Seamons, Hartwell, Aylesbury.

**COCHIN-CHINA** (Any colour).—First, E. Smith, Middleton. Second, R. J. Wood, Brinscall Hall. Third, W. Dawson, Hopton, Mirfield (White). Highly Commended, C. H. Brierley, Rhodes House. Commended, J. Bell, Kirkgate, Thirsk (Brown Partridge); F. R. Pease, Southend, Darlington; T. Wrigley, Tong, Middleton (Buff).

**SPANISH** (Black).—First, H. Beldon, Gilstead, Bingley. Second, L. J. Crossly Manor Heath, Halifax. Third, G. Bridle, Northern Lane, Didsbury. Highly Commended, J. L. Lowndes, Hartwell, Aylesbury; J. Wood, Brinscall Hall; F. R. Pease, Southend, Darlington. Commended, J. Marchant, Halifax.

**BRAHMA FOOTER** (Any colour).—First, H. Lacy, Hebden Bridge, Yorkshire. Second, W. Hargreaves, Newchurch Road. Third, J. Wood, Brinscall Hall.

**HAMBURGS** (Golden-pencilled).—First, Sir St. G. Gore, Bart., Hopton Hall. Second, C. Tattersall, Myrtle Grove, Waterfoot. Third, H. Beldon, Gilstead. Highly Commended, E. Smith, Middleton. Commended, H. Crossley, Broomfield, Halifax; A. Nuttall, Newchurch.

**HAMBURGH** (Silver-pencilled).—First and Silver Cup for best of *Hamburgs*, Sir St. G. Gore, Bart., Hopton Hall. Second, H. Beldon, Gilstead, Bingley. Third, D. Illingworth, Burley, near Otley. Highly Commended, E. Hindle, Wood Noak, Accrington. Commended, J. Platt, Dean, near Bolton.

**HAMBURGH** (Golden-spangled).—First, H. Beldon, Gilstead, Bingley. Second, A. K. Wood, Burnside, Kendal. Third, J. Whitworth, Bury, Lancashire. Commended, R. Tate, Green Road, Leeds; Sir St. G. Gore, Bart.; J. Roe, Hadfield, Manchester; W. Driver, Keighley.

**HAMBURGH** (Silver-spangled).—First, Miss E. Beldon, Gilstead, Bingley. Second, J. Fielding, Newchurch, Rosendale. Third, Sir St. G. Gore, Bart., Hopton Hall. Highly Commended, A. K. Wood, Burnside, Kendal; J. Fielding. Commended, J. Fielding.

**POLAND**.—First, C. W. Brierley, Rhodes House, Middleton. Second, H. Beldon. Third, Miss E. Beldon. Highly Commended, S. Ashton, Mottram, Cheshire. Commended, H. Snowden, Horton, Bradford.

**ANY OTHER VARIETY**.—First, H. Beldon. Second, J. Smith, Hebden Bridge (White Sultans).

**SELLING CLASS** (Any variety).—First, H. Beldon (Cochins). Second, C. W. Brierley, Middleton. Third, D. Parsons, Cueden Hall, Preston (Brahmas). Highly Commended, Messrs. Baxter & Furness, Accrington (White *Polands*). Commended, H. Beldon (Hamburgs); T. Dyson, Halifax (Polands).

**GAME BANTAM COCK** (Any colour).—First and Cup, J. Munn, Shawlough, Newchurch. Second, G. Maples, Wavertree, Liverpool (Black Red). Third, T. Kenyon, Blackburn (Black Red). Highly Commended, T. Eastham; E. Smith, Middleton; M. Turner, Preston. Commended, A. Clegg, Accrington; J. Rhodes, Thornes near Wakefield; H. M. Wellington, Oakham, Rutlandshire (Black Red); J. W. Morris, Rochdale (Black Red); C. W. Brierley, Middleton; Sir St. G. Gore, Bart.

**GAME BANTAM** (Any colour).—First, D. Parsons, Cueden Hall, (Brown Red). Second and Third, C. W. Brierley, Middleton. Highly Commended, J. Munn, Shawlough, Rosendale; J. Rhodes, Wakefield; C. W. Brierley; W. F. Entwistle, Otley, Yorkshire (Files). Commended, D. Ashworth, Halifax; D. Parsons (Greys); Sir St. Gore, Bart., Wirksworth.

**BANTAM** (Any other variety).—First, C. W. Brierley, Middleton. Second, F. R. Pease, Darlington (Buff *Cochins*). Third, W. Harvey, Sheffield (White). Commended, C. W. Brierley; F. R. Pease (Silver-laced); H. Beldon (Gold-laced); Sir St. G. Gore, Bart.; C. W. Brierley.

**TURKEYS**.—First, E. Leech, Rochdale. Second, G. W. Brierley, Middleton. Highly Commended, T. Houker, Revidge, Blackburn.

**GEES**.—First, B. Baxter, Elslack Hall. Second, T. Houker, Revidge, Blackburn.

**DUCKS** (Aylesbury).—First, Mrs. M. Seamons, Hartwell, Aylesbury. Second, F. M. Hindle, Haslingden. Highly Commended, F. M. Hindle. Commended, Mrs. M. Seamons.

**DUCKS** (Rouen).—First, H. Beldon, Bingley. Second, T. Houker, Blackburn. Highly Commended, W. Taylor.

**DUCKS** (Any other variety).—First, D. Parsons. Second, W. Moorhouse. Highly Commended, C. W. Brierley; T. C. Harrison. Commended, J. A. Bell; H. Bell.

**PIGEONS—Carriers**.—First, J. Hawley, Burnley. Second, H. Snowden, Horton, Bradford. Highly Commended, J. Fielding, jun., Rochdale. **Tumblers**.—First, E. E. M. Royd, Ashby-de-la-Zouch. Second, H. Yardley, Market Hall, Birmingham. Highly Commended, H. Yardley; J. Fielding, jun., Rochdale. Commended, W. J. Corbridge, Blackburn; J. Thompson, Bingley; J. Hawley, Burnley. **Barbs**.—First, W. J. Corbridge, Blackburn. Second, H. Yardley, Market Hall, Birmingham. Highly Commended, R. Thompson, Moredale Hall; B. Consterdine, Brookfield, Littleborough. Commended, C. Parkinson, Accrington. **Owls**.—First and Second, J. Fielding, Rochdale. Highly Commended, W. J. Corbridge, Blackburn; H. Yardley, Market Hall, Birmingham. Commended, R. Thompson, Moredale Hall. **Pouters or Croppers**.—First, H. Snowden, Great Horton, Bradford. Second, H. Yardley, Birmingham. Highly Commended, E. E. M. Royd, Ashby-de-la-Zouch. **Fantails**.—First, H. Yardley. Second, W. Westwell, Great Horwood. **Turbits**.—First, R. Thompson. Second, H. Yardley. **Dragons**. First and Second, H. Yardley. Commended, J. Thompson.

*Trumpeters*.—First, H. Yardley. Second, H. Middleton. Highly Commended, E. E. M. Royd. Commended, W. J. Corbridge; T. Barker. *Any other variety*.—First, H. Yardley. Second, O. A. Young.

The Judges were Mr. Joseph Hindson, of Everton, Liverpool; and Mr. Edward Hewitt, of Sparkbrook, Birmingham.

### THE SUBSCRIPTION FOR MRS. CHITTY AND FAMILY.

ALTHOUGH I can add nothing to the eloquent appeal of "Our Chaplain" on behalf of the widow and fatherless, I am very desirous that bee-keepers should not be behind-hand in the good work. I recognise the names of some of our fraternity in the list of subscriptions already published; but in such a cause I may perhaps venture to remark that the Cornish motto of "One and All" should be promptly and energetically acted upon, if the good work now in hand is to result in substantial benefit to the bereaved wife and fatherless children of one who has so suddenly disappeared from amongst us.—A DEVONSHIRE BEE-KEEPER.

### ACCLIMATISATION AT THE ANTIPODES.

I AM indebted to Mr. Edward Wilson, late President of the Association, for the perusal of the third annual report of the Acclimatisation Society of Victoria.

Alas! that I should have to use the word "late" in connection with Mr. Wilson and the office which he has so ably filled from the very commencement, and alas! for the cause which has compelled him to press his resignation. We learn from this report, that "it is with unfeigned regret that the Council have to state that, in consequence of a complaint in his eyes rendering necessary another visit to Europe, Mr. Wilson has, in spite of their earnest remonstrances, pressed upon the Council his resignation as President, which resignation the Council have most reluctantly accepted." Mr. Wilson is accordingly once more among us, and this time unfortunately with the view of seeking relief from the skill of the British faculty. That his restoration may be both speedy and complete must be the earnest prayer of every well-wisher to the cause of acclimatisation and of progress.

Foremost among the Society's achievements during the past year comes, of course, the successful transportation of salmon ova to Australia. Regarding this feat the Council announce that, although "from the few ova that were retained in Victoria it cannot be asserted with certainty that salmon is yet established in the colony, enough has been done to show that there are no insuperable difficulties in the way; whilst in Tasmania complete success has been attained."

Another subject of congratulation is the introduction of the gouramier from the Mauritius. Twenty-four of these desirable fish reached Melbourne alive, and there is every reason to hope these will establish the species in the colony.

The alpaca experiment, from which so much good was expected, appears unfortunately to have turned out an almost total failure. Nothing daunted, however, by his late ill success, Mr. Duffield is about to undertake a second attempt to introduce the alpaca into the colony.

The following paragraph, relating as it does to the Italian bees exported from my apiary in 1862, is peculiarly interesting: "As a contribution of very particular interest to the cottager, the introduction of the Ligurian bee may be adduced, that insect being probably, from its industrious and wonderfully prolific properties, the most valuable in the world. This bee is multiplying with almost incredible rapidity, and will soon be accessible to all classes." Connected with this subject, I find an advertisement in *The Australasian*, of the 24th of December last, offering stocks of Ligurians for sale at £10 each, whilst swarms of common bees are offered at 20s. each.

Just at this time, when such praiseworthy efforts are being made to check the destruction of small birds, both in this country and on the continent, the following paragraph may be deemed instructive as well as interesting.

"In a country so subject as this [Australia] to the ravages of insects, the case of the agriculturist has always been carefully considered. Hundreds of industrious farmers have

even this year been ruined by the caterpillar, and similar visitations must necessarily be expected. The introduction of insect-destroying birds has therefore been carefully attended to; and with this has been combined an effort to surround our colonial residences with those interesting associations which constitute no slight portion of the charms with which the name of "home" is ever surrounded. The thrush, the blackbird, the skylark, the chaffinch, the sparrow, the Chinese sparrow, the Java sparrow, and a most active and interesting bird the Indian mino, may now be considered thoroughly established, and are rapidly extending by natural means through the colony. The goldfinch, the linnet, the greenfinch, the yellowhammer, the ortolan, the canary, the robin, and many kinds of the smaller birds of other countries are being accumulated in the aviaries of the Society, and many of them have already bred there. The nightingale and the hedge sparrow have been promised us by benevolent ladies at home, and the Queen herself has made an effort to supply us with the rook."

Appended to the report are papers on various subjects read at the Society's meetings. The entire pamphlet is eminently interesting and highly suggestive, and most heartily do I, for one, wish success to the Acclimatisation Society of Victoria.—A DEVONSHIRE BEE-KEEPER.

### TRANSFERRING BEES—STOCK INACTIVE.

I HAVE two stocks of bees, each two years old, in old straw hives, and I wish to transfer them into two Woodbury hives; will you have the kindness to tell me what is the best time of the year for performing the operation?

Would you also advise me respecting a stock in a Woodbury hive? It appears weak, only a few bees coming out; while in my other stocks all is now bustle and activity. Near the Woodbury there were between thirty and forty dead bees the other day and several dead ones on the alighting board. On looking in at the window to-day there was nothing but empty comb to be seen. Has the hive been plundered, do you think; or would you advise feeding? I lifted it off the stand yesterday, and it was by no means light. Still, there appears to be nothing going on inside beyond a lazy crawling about of the bees.—A SUBSCRIBER.

[Next month (May) will be a very good time for the operation, which is most conveniently performed on well-populated, but not over-crowded stocks. Your Woodbury hive may very probably be queenless, but with a hive of this description ten minutes' internal examination will solve the mystery. The readiest way of accomplishing this is to commence by removing a side comb; then lift out and examine comb after comb, depositing each in the notch occupied by its predecessor, and finally placing the comb first taken out at the opposite side of the hive to that from which it was taken. In repeating the operation the process should be reversed, so as to restore the combs to their original position.]

### ARTIFICIAL SWARMING.

I HAVE several stocks of bees in common straw hives, and this season I want to increase my stock of bees considerably in improved hives and boxes; but I do not want to run the risk of swarming, as I am not at home during the day, and the consequence would be that most of them would be lost, as was the case last year. Now, will you be good enough to inform me if the following plan of artificial swarming will answer, or any improvement upon it? I intend towards the middle of this month to place under the stock hives the empty hives I want to be tenanted, but I do not know how long it is necessary to leave the stock hive at the top, and which you remove to a fresh place. I shall be much obliged if you would answer the above questions, or suggest any other plan. I cannot run the risk of letting my hives swarm. Do you think it better to confine the bees in the fresh hive for a day or two after the stock hive is taken off?—J. A.

[The plan you describe will not result in the formation of artificial swarms, but if you stop up the entrances of the old hives and compel the bees to work up through the new ones they will most probably make combs in the latter, and ultimately transfer the seat of breeding to them. When

this is effected the old hives may be removed, and their contents appropriated by the apiarian; but the time required to effect the change depends entirely on the season and the strength of the colonies. This appears at first sight an easy mode of transferring bees to new hives, and has been frequently recommended as such. It is, however, open to the serious objection that they are very liable, under such circumstances, to construct an undue proportion of drone comb, and when this takes place it is fatal to the future prosperity of the stock. Your best plan will be to multiply your colonies and stock your improved hives with artificial swarms formed in the manner described and recommended by Mr. Woodbury in No. 161 of our new series.]

### HONEY GATHERING FROM CLOVER.

"P. M." says he takes one crop off the clover and then one from the heather, but he can never take one off the clover, for the tongue of the honey bee is too short, and never takes anything from clover. The bumble or humble bee has a long tongue, which can enter the clover.—T.S.

["P. M." doubtless meant the white clover, although he did not specify it. Although the honey in red clover is not accessible to the hive bee, the white variety is well known to be one of the best, if not the very best, of our bee flowers.]

### PARROT MANAGEMENT.

SALT, meat, and brass are all pernicious to Parrots. Meat produces liver complaints; contact with brass, cancer of the tongue—of this I have seen a miserable victim. It should be avoided in all cages as they will gnaw it. There should be no wire grating at the bottom of their cages, but dry, well-sanded or gravelled boards. They like to roost flat-foot at the bottom. Sometimes Parrots in a wild state roost in the hollows of trees and rocks, and it is cruel to keep them with their claws always painfully stretched over round and slippery perches. Two perches should furnish their cage, one less than the other. This eases the feet, which sometimes become galled, and the birds can hardly stand, yet by-standers do not comprehend their uneasiness.

Male birds are subject to fits in the spring, and some to cramp in the stomach, which makes them stagger. Place the bird on a flat bottle of warm water, well wrapped round in flannel not to scorch his feet; he likes the warmth, and will sooner recover. Parrots eat the stones rather than fruit itself of grapes, cherries, and plums. These last must be cracked for them. They delight in the green buds and young seed of cabbage, and Indian corn when young, and will tear off its many sheaths and devour two or three if they can get them, also vegetable marrow boiled and caravansa white beans, broad beans as well. An occasional nutmeg does the Parrot good. A capital contrivance for a perch is to have a round tabular dish in the middle, and then two perches running under it thus—

The two o o hold water and sop, and the table, screwed to the upright perch, the general food; the whole must be kept well scrubbed and clean. Then the bird makes no mess about the room.—ORNITHOLOGIST.

### LURING BIRDS TO A HOME.

If "AMATEUR" will procure eggs of the birds she (for "A. J. G." presumes "AMATEUR" is a lady) wishes to have, and take the Sparrows' eggs carefully out of the nests and replace them with an equal number of Bullfinch or Linnet eggs, the Sparrows will hatch and rear them if the transfer is done with discretion. The eggs to be hatched must be taken very gently and carried from one nest to the other in cotton or wool in a box; they must be handled as little as possible, and, of course, put into the Sparrow's nest while the bird is off it, and the nest must not again be visited, otherwise the bird will forsake it.

I am not sure whether a Sparrow would hatch Blackbirds'

or Thrushes' eggs, but I fancy not; however, it might be worth trying.

"A. J. G." has seen Starlings induced to build by having a small packing-case, made to resemble a small dog-kennel, and placed at the top of a pole. On the little platform in front of the house the old birds used to feed their young, a most amusing sight, and the chattering of these birds is very curious. The pole was a common larch pole 10 or 12 feet high, the box was about 18 inches long and about 14 inches high, and the little platform was about 18 inches square in front of the house, it was a projecting piece from the boards on which the house was fastened. The birds came back to it year after year.

Do Brahma Pootras generally lay while they are young? "A. J. G." has some hatched last April, and they are said not to have laid yet.

AN "AMATEUR" asks "What can I do to induce Bullfinches to come into my garden, and what sort of meat should I provide?" I heartily join him in this inquiry in the hope that some one will point out a means by which he may be supplied with Bullfinches, Chaffinches, &c., to the benefit of myself and others who grow pear, plum, cherry, and gooseberry trees, and thus be the means of transferring those troublesome pests to "AMATEUR."

We can willingly dispense with them and would recommend him to try the plan of growing such trees, of the buds of which they are so fond that I have had some trees not only rendered fruitless, but nearly destroyed by them at this season of the year. The centre of the bud is enclosed and blanched, therefore sweet. It has been said by some they find grubs inside, if grub is intended I readily fall into that opinion, but I have repeatedly examined buds and never yet have found grubs within any of the buds on their favourite trees.—W. G.

OUR first TAME PHEASANT laid on the 5th of April—a Chinese hen.—J.

YESTERDAY (April 5) I heard and saw the Chiff-Chaff, being the first of our summer visitants I have observed this year.—ARTHUR SPARY, *St. Alban's*.

### OUR LETTER BOX.

CRYSTAL PALACE POULTRY SHOW (*D. N.*).—Apply to the Secretary, Crystal Palace. We do not know.

DUCK LAYING SOFT EGGS (*J. J. H.*).—Your Ducks are over-fed. Give them whole oats, in a trough, with plenty of gravel, the whole covered with water. Meal and worms are not the very best of food. Your Guinea Fowls ought to lay in a fortnight.

HATCHING PARTRIDGE COCHIN EGGS (*Partridge Cochins*).—We believe their eggs will be good for a month after laying. Some limit the time to a fortnight.

COCHIN COCKEREL'S LEGS PARALYSED (*F. G.*).—Your cock is suffering from cramp, or from weakness, or both; probably the latter. If he is now nine months old, he would be an August bird; before he was out of harm's way he was overtaken by the long winter which has just terminated. He has grown in length and height, but not in strength. It is at all times a mi-take to keep an autumn bird for a breeder, but doubly so after such a trying time. His treatment will be castor oil every other day for a week, followed by stimulating food, as bread and ale, or raw yolks of egg. In our opinion he is not worth saving.

CHICKENS DYING BEFORE COMPLETELY HATCHED (*Poultry*).—Your eggs are too dry; moisten them every day for a week before hatching. We should think your hens had lice. Let them have plenty of dust in their haunts. To bring your Hamburg cock into showing condition there is no better food than ground oats mixed with milk. Roasted fresh meat, chopped fine, and chopped eggs, are also good.

BUFF AND PARTRIDGE COCHINS IN SAME RUN (*Percy Cross*).—We advise you to wait at least a month. Others, and good authorities, will tell you a fortnight is enough.

PARROT MANAGEMENT (*A Subscriber*).—Your Parrots may be fed on bread and milk, soaked Indian corn, and such fruits as they will eat. Let them have a soup plate, or some shallow vessels of water, to bathe in; but if they do not bathe voluntarily give them a good shower bath from a watering-pot during fine weather. Their plucking off their feathers may arise from irritability in the skin, caused by improper food, as meat, or from insects. If from the latter cause dust some flowers of sulphur among the feathers. The raw place may be anointed with unsalted butter or lard. When the skin is more healthy, new feathers will grow where those have been plucked out. If bitten off, the stumps will be replaced at the moulting time. To teach them to talk you must make them tame and familiar, and constantly repeat the words distinctly to them which you desire them to learn.—B. P. B.

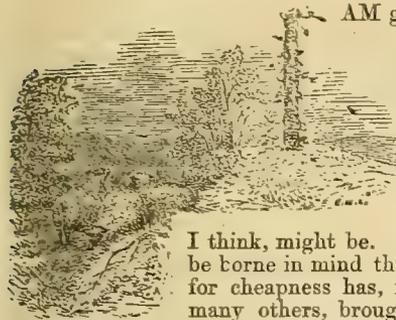

BEES DYING (*J. Bryan, Royston*).—Your bees most probably died of dysentery, brought on by long confinement during the late protracted winter. If there be nothing amiss with the combs beyond a slight mouldiness, we should not be afraid to use the hives as they are.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 60.6°, and its night temperature 36.1°. The greatest heat was 77° on the 19th, 1854; and the lowest cold, 18°, on the 24th, 1854. The greatest fall of rain was 0.60 inch.

GLASS FOR HORTICULTURAL PURPOSES.

AM glad that Mr. Pearson has called attention to the indifferent quality of sheet glass, and I can confirm all he says respecting it, as it is certainly not so good as it ought to be, and,

I think, might be. It must, however, be borne in mind that the competition for cheapness has, in this case, as in many others, brought a very inferior article into general use; and it is to be

feared that much of what is rejected for dwelling-house windows is worked into horticultural buildings. The remedy, however, lies, to a certain extent, in the hand of the builder, and, by insisting on only good clear glass, he may obviate much of the annoyance caused by breakages from natural causes, provided the glass be also well tempered, and in other respects good. Sheet glass, however, has some defects in its manufacture which it is difficult to rectify; and I very much question whether any of it is as strong as the old crown glass of the same thickness, but very little of the latter was made anything approaching the thickness that is now given to sheet glass in most cases; and glaziers have some excuse for clinging so pertinaciously to the old kind whenever it can be used to advantage. The subject is well worthy of a discussion in the pages of THE JOURNAL OF HORTICULTURE, and I hope to have the opinion of some of the glass manufacturers. In my own case I may say that, in all fixed glazing, I have for several years advocated the use of sheet glass of 26 ozs. to the foot; and if this be good, and in squares not exceeding 2 superficial feet, the breakage by natural causes ought not to be much. I attribute much of the damage done to glass in frosty, and even in hot weather, to such glass being, as Mr. Pearson says, "badly annealed;" and, in some cases that have come under my eye, the worst kind in this respect is the Belgian glass, which, on account of its cheapness, has been largely imported into our markets. To all appearance this glass is equal, or perhaps superior, to our own of the like kind; but it certainly is more liable to break, and consequently causes great annoyance.

I should much like if some one conversant with the manufacture of glass would give us the respective amount of elasticity in Belgian and British sheet glass of the kinds usually employed in horticultural buildings; for, however small may be the elasticity of either, there is no question that the one which possesses the most is least likely to be broken, more especially from natural causes. I am certainly of opinion that home-made glass is less brittle than that from the continent; but as to the causes which render it so I can give no opinion. Perhaps the

raw material may be a better, or, as Mr. Pearson says, the annealing process may be better understood or carried out; while, on the other hand, Belgian glass presents quite as even a surface, and is, perhaps, more white than the same kind made at home. I have occasionally made some experiments with long narrow strips of glass by bending them almost to the breaking point, and a piece 2 feet long will bend considerably. What opportunities I have had of trying both kinds of glass lead me to give the preference to the home-made article for that quality which may be designated toughness. I may, however, be mistaken, and would much like to hear the opinion of others on this matter. I may also remark that the stouter kinds of glass seem to resist the action of frost better than the old thin crown glass, but there are other causes of breakage which are not so easily accounted for. A few remarks on these may, perhaps, throw some light on the subject.

In glazing with large squares, or rather with long ones, it is not unusual for glaziers to fasten them in their place with small nails, and, if there should be a bend in the glass, to let the nail press that part, so as to have it nearer a level than it was before; the result often is that, in a day or two afterwards, the square is broken. Now, how is this to be accounted for, as no fracture was visible at the time the square of glass was fixed in its place? but such cases are of frequent occurrence. The only theory seems to be that change of temperature acts on the glass, and compels it to disengage itself, or partially so, and when the resistance of the nail cannot be overcome a fracture is the result, and I have seen the same thing occur after a cold night; but the breakages attributable to this cause are few compared with those which arise from the action of heat and cold in another way. One of the most common of these is the freezing of the moisture in the overlaps of the roof, which, in the case of thin glass, causes great destruction, more especially if such overlaps are wide, and admit of a large amount of moisture being collected, and, on its expanding with frost, a longitudinal crack is formed in one of the squares; this, though almost imperceptible at first, only requires a very slight pressure of the finger to make it run a long distance up the square. This is more especially the case with the old crown glass; but sheet glass is liable to the same evil, though to a less extent, in consequence of its being thicker, and lying more flatly on its bed. Tightness in the glazing-bar may, perhaps, at times occasion a breakage, but I do not think this is often the case; neither do I consider that the expansion and contraction of metallic bars is to be blamed for the loss of glass so often attributed to that cause. I am more disposed to think that vibration has something to do with the breakage; and in lightly-constructed iron houses the loss is often considerable, especially if the squares are small, and the glass thin. Hailstorms are an exceptional cause of damage, which it would be well to guard against by only using thick glass; but the loss from such causes is only likely to occur once or so in a lifetime, but when they do they are very disastrous. I have seen upwards

of £500 damage done to the glass in a garden, and believe this has been exceeded in some other cases.

Since the first introduction of sheet glass, its manufacture has certainly improved much in one respect—its surface is more even and smooth than it was at first, when the face of much of the glass that was then made presented little else but a succession of convex lenses, which told with destructive effect on the plants underneath. These defects have certainly been modified; I wish I could say the same of the little specks that show themselves in greater or less number on all low-priced glass, and certainly do no good. These specks are more common than of yore, and tend much to detract from the general character of sheet glass. In regard to toughness, I fear no improvement has taken place; on the contrary, I think it is not so good. Possibly if our manufacturers were told of the defect complained of by Mr. Pearson and others, they might improve the article; at all events there seems no reason to rest satisfied with it as it is, and as its brittleness no doubt arises from its imperfect annealing, it is not likely that an improved mode of performing that process will much increase the price. As the manufacture of sheet glass has of late years vastly increased, some mode of furnishing a better material may be looked for, provided the consumer do not too rigidly insist on a low price being given for it. With regard to the manufacture of sheet glass, I believe that instead of being blown into a globe-shape when taken from the furnace, it is worked into a hollow cylinder, and while in a semi-fluid or soft state, one side of the cylinder is slit up, and I presume the ends cut off, and the glass sheet is then opened out and flattened. This process, as will be seen, must expand the inner side, but whether that affects the temper of the glass or not after annealing is more than I can say. A similar expansion of the inner side takes place in the manufacture of crown glass, which is blown through a long iron tube into a globular shape before a very hot fire which keeps the mass soft, and while in that state a hole is struck in that part of the globe immediately opposite to the side where it is attached to the iron rod, and being held in front of the fire and whirled round rapidly near to it the hole enlarges, and the globe by degrees becomes compressed, then basin-shaped, and as it continues to revolve it becomes flatter, but is never quite flat, always being more or less slightly saucer-shaped according to the dexterity of the workman who gives the finishing turn. This glass is then broken from its fastening in the centre to the iron tube and carried to an oven to cool gradually, the place where the tube was attached to it forming the "bullions," that are sometimes used in stables and other places. I believe, however, that sheet glass has in a great measure superseded the old crown glass, except in cases where the glazier has the privilege of supplying whatever kind he likes, and then the greater ease with which crown glass is cut, especially for small squares, when its curved character does not matter much, offers a great temptation to him; but for all horticultural structures sheet glass is so convenient that the old crown glass may be said to have fallen into disuse, excepting for repairs to older buildings where it was originally used, and where a thicker kind could not well be employed.

Some years ago a description of rough plate glass was strongly recommended by some as possessing qualifications in which the sheet glass at that time was deficient, but it has failed in some of the points aimed at, and is certainly not so much used at the present day as it was six years ago. Its principal merit is thickness, and, consequently, strength, but though not so clear as its rival, it is not sufficiently opaque to allow of shading material being dispensed with in the case of plants in flower, which was set forth as one of its merits, and in appearance it is far from equal to good sheet glass, and assuredly sooner becomes dirty. I have not had much experience with it myself, and my observations are based on what I have seen elsewhere. I hope, however, to see a better class of plate glass brought into use for horticultural purposes than any yet offered to us, clear, smooth, and transparent, or, when wanted, of any hue to suit the requirements of plants. Plate glass of a good quality is certainly too dear for that purpose yet; but it is not very many years since it was double the price it now is, and though much of the reduction in price is owing to the repeal of the duty, it is not entirely due to that cause, and I hope

to see other modes of manufacturing it, so as to present it to us in a cheaper form.

Connected with this subject is that of glazing, which certainly is also capable of further improvement, but I confess that I am unable to offer any hints as to how that may be effected. I look forward to putty being superseded by some adaptation of india-rubber, or, perhaps, by squares of glass made to fit like pan-tiles, one edge overlapping the other.

In conclusion, I must again express a hope that some manufacturer of glass will throw some light on the complaints so justly made against sheet glass, and at the same time point out a remedy. This, it is to be hoped, will not prove an expensive one, as the increasing demand for glass houses renders the cheapness of the material they are glazed with an indispensable consideration; but if greater efficiency can be attained at only a trifling increase of expense, then let no one begrudge that outlay.—J. ROSSON.

#### LUCULIA GRATISSIMA CULTURE.

THIS, though commonly grown in a stove, is more properly a greenhouse plant, flourishing under the same conditions as the Camellia, and making an admirable conservatory plant. Planted out in the conservatory border it attains a large size, and has a very striking appearance when covered with its extremely fragrant and beautiful flesh-coloured blossoms, in November and onwards till spring. It is also a good pot plant, and does well in a sitting-room when in flower.

Presuming that it is to be planted out in a greenhouse or conservatory border, the soil should be dug out to the depth of 2 feet, and 2 or 3 feet in width; then 6 inches of brickbats or coarse rubble should be laid at the bottom, it being important to have perfect drainage, and this should be covered with a layer of turf, grass side downwards, preference being given to turfy heath mould from a common, cut 3 inches thick. Thus there will be space left for 15 inches of soil, but to allow for settling, 18 inches should be put on; it may consist of one-third rather strong yellow loam, taken 3 inches thick from a pasture, and laid in a heap for six months, or it may be used fresh for border-making, but not for growing plants in pots; to this add two-thirds of sandy peat, also taken off 3 inches thick, and from where the soil abounds in particles of fine silicious sand. Chop up these materials roughly with a spade, breaking and blending them together, but on no account screening. It is well to form the border when the soil is in a tolerably dry condition. A trellis should be provided for the plant, and the situation ought to be light and well ventilated, particularly during the early autumn and winter months; but when making new growths, the *Luculia*, like the *Camellia* and *Azalea*, requires slight shade. The best time to plant is early in spring. Select a plant that has not become pot-bound, but one of free growth and not more than a year old; a cutting of the previous year will do. If an old plant is put in, the ball ought to be broken and the roots spread out, the collar being elevated rather than kept low in the soil.

After growth has commenced in spring, and during the summer, the *Luculia* requires to be watered freely, but in September the supply should be gradually diminished, until the minimum is reached in the beginning of October. After that period water sparingly, keeping the soil neither dry nor wet, for in the latter case the fibres of the roots are soon injured and the buds fail to open, and a deficient supply of moisture is attended with similar results, the leaves falling as well.

If in the first year the plant exhibit a tendency to become bare of shoots, cut it in at planting, and stop during the summer. This will induce the production of side-shoots. Be careful not to overcrowd the plant, but train the shoots in regularly, and so that light and air may be freely admitted to all parts. It will not flower much the first year, nor, indeed, until the border become occupied with the roots. In the second year it will grow vigorously, but the shoots must not be shortened nor stopped except before growth commences. Two years after planting, or in the autumn of the second year, it will cover about 50 feet of trellis, and in most cases flower freely, producing cymes of flowers 5, 7, or 10 inches in diameter.

The *Luculia* is rather subject to attacks of red spider, and should therefore be syringed overhead during the growing season up to September, directing the force of the water against the under sides of the leaves. Owing to this pest being allowed to remain undisturbed for a length of time, we frequently see the plant with a few leaves at the ends of the shoots only, and, consequently, presenting a very unsightly appearance. Any house kept at greenhouse temperature will grow this plant well, it having been found to succeed in houses from which frost was only excluded, the thermometer occasionally falling as low as 36°.

When grown in pots the same compost is employed as for planting out, and the greatest care must be taken to render the drainage efficient. Potting should be done in spring just before growth commences, and carefully so as not to injure the young fibres, the plant being impatient of having its roots frequently disturbed. After potting, in March or April, or if this is not required the drainage having been looked to, the plant may be cut in if out of shape, and placed in a temperature of from 50° to 55° by night, preserving a moist atmosphere, frequently syringing overhead, and giving slight shade. After the growths are made the plant should be gradually hardened, have more light and air, which will usually be the case in July, and be placed out of doors in a warm situation, but screened from the midday sun. By the middle of September it should be returned to a vinery, or any light, airy house with a temperature of 50°. It will then grow and form its beautiful flower-heads. Whilst out of doors the pot should be protected, and the soil kept moist, otherwise the fibres will perish, and though the flower-heads may form they will fall off without expanding. If a cool house is at command, it would be better to place the plants there, an airy greenhouse being a good situation, and the supply of water should not be more than sufficient to keep the soil moist, syringing, however, if there is the slightest indication of red spider.

Those who have not the means of giving the plants a little extra heat whilst making new growths, may continue them in the greenhouse until the middle of June, when they may be placed out of doors in a warm situation, plunging the pots in ashes, or surrounding them with moss to prevent the destruction of the fibres, at the same time giving plenty of water and protection from hot sun. In September they should be returned to the greenhouse, though a vinery or cool stove is better, and they will grow freely, and form their flower-heads, which will expand and diffuse their fragrance during the winter. Under this treatment, and making the wood in autumn, the *Luculia* usually flowers more certainly than when forced into growth in the spring and early summer, though the flowers are not so fine, but not so liable to fall before expansion. This is usually caused by the destruction of the fibres, in consequence of the soil being sodden after the growth has been made. Another cause is red spider exhausting the leaves of their juices, and preventing the ripening of the wood.

The *Luculia*, in whatever structure it is grown, requires a certain amount of shade, and a plentiful supply of water at the root, and moisture in the atmosphere, and when growth is made exposure to more light, a well-ventilated, drier atmosphere, and a gradual diminution of water at the root, yet never allowing the soil to become so dry as to affect the foliage. Though usually treated as a stove plant it will do much better in an intermediate house, and still better planted out in a conservatory border. It is frequently attacked by green fly, especially the flower-heads, the remedy for which is fumigation with tobacco.

It is propagated from cuttings of the half-ripened shoots, taking off the points of the shoots with two or three joints, removing the lowest leaves, and cutting transversely below the lowest joint. Insert the cuttings down to the lowest leaves in sandy peat and loam, with a large proportion of silver sand, and plunge the pot in a brisk bottom heat of 75° to 85°, covering with a bell-glass if the air is dry. When rooted gradually harden off, and repot, keeping the young plants under rather than over-potted. See that the drainage is efficient. Stop at the third joint, or the fifth at the most, but do not stop the shoots that are expected to bloom in the ensuing winter, except prior to the growing season. Young plants will generally flower at one year old, and a small plant in an eight-inch pot forms a very ornamental object for

a sitting-room. The *Luculia* is one of the finest of winter flowering plants, and deserves a place wherever there is a conservatory, greenhouse, or cool stove.—G. ABBEY.

#### SOIL AND SITUATION FOR RHODODENDRONS.

MR. ROBSON, in an article on the Rhododendron, justly remarks that they will accommodate themselves to a variety of soils. Many years ago, when on a visit to my brother in the west of Cornwall, I found him planting some of the best sorts of Rhododendrons in yellow loam taken from a coppice wood, which lay high and dry. I remarked to him that he could not expect much growth in that kind of soil. His reply was, "I certainly do. All you see around are planted in soil of the same sort;" and I was obliged to acknowledge that I had never seen plants more healthy.

About ten years afterwards I again saw them in full bloom, and a more lovely sight could not be seen—the shrubs, from 6 to 8 feet high, one mass of flowers in endless variety. The soil these fine healthy plants were planted in was a heavy yellow loam, with not a particle of peat in it.

His method of planting was to have a plentiful supply of leaves and dung well mixed up with the yellow loam, and as soon as the plants were planted to soak them well with water—not a dribblet, as we often see, but a regular flood. A few days afterwards, when settled, the soil was closely pressed around them.

The first season after planting all were kept mulched with dung. Sandy peat, or any other variety of peat, would not answer for Rhododendrons in that locality. This may be accounted for, as it is in a mining district, where nearly all the peat soil is impregnated with minerals injurious to vegetation.

Previously to seeing the above I had been to much trouble and expense in obtaining from a distance peat to plant some of the best sorts of Rhododendrons in. In the locality in which I now reside (the west of Devonshire), may be seen Rhododendrons upwards of 20 feet high, and nearly as many feet through, growing in the natural soil, which varies from light hazel to heavy yellow loam, resting on rotten slate and some on freestone. Here they seed and produce their seedlings, not by twos or threes, but by tens of thousands, in crevices of rocks, by the sides of walks, and even on old Oak trees—in short, in any place where seeds can find a resting-place to vegetate on. Here they grow and flower in all the varieties that *Rhododendron ponticum* has produced; miles of them grow in great luxuriance by the sides of drives and walks, and interspersed amongst trees, woods, and shrubs, where they assume the appearance of indigenous plants.

I think the situation has as much to do with the growth of Rhododendrons as the soil. Here we have abrupt hills and dales, and sheltered from the northern and eastern blasts; where the Tamer meanders through the valley, and rivulets join it in its onward course, moisture ascends, and woods, trees, and hills give shelter and shade. In such situations the Rhododendron for the last fifty years has found a genial home. Previous to that time a Rhododendron had not been seen within ten miles of this locality. Here, as Mr. Robson remarks, the Foxglove is at home; Ferns abound; lichen and moss cover the hard-wood trees; and trees of the Fir tribe become prematurely old. Here also the Primrose, wild Hyacinth, Wood Anemone, Columbine, and a host of other indigenous plants cover the ground. In such localities, where Nature has been so bountiful, the Rhododendron will always find a suitable home.—E. C. E.

PICEA PINSAPO.—I am glad to hear reports made of this gem of the pinetum, and in reply to Mr. Gardiner, who at page 266 mentions one 24 feet high, I beg to state that a very fine one at Linton Park is 29 feet high, and so densely clothed with branches thickly set with foliage, that a person in walking round it can only catch a very slight glimpse of the bole in one or two places; for about 20 feet the whole is a perfect cone. The extreme branches give a diameter of about 19 feet, and in appearance nothing can be really more handsome. I may add that the growth of the last few years has averaged 2 feet each year; the soil is moderately deep, but dry, and the situation somewhat sheltered

In close contact with it is a *Cryptomeria japonica* about 40 feet (or nearly that height, for I did not measure it), and perfectly straight, the slender tapering top running up like a fishing-rod, while the diameter of the branches does not anywhere exceed 12 feet. As compared with others this is considered a pretty good specimen, but the most admired tree we have is *Pinus insignis*. I have not been able to measure this accurately, but will do so on the first opportunity.—J. ROBSON.

### BLIND STRAWBERRY PLANTS.

MANY of your correspondents are constantly complaining of their Strawberries "going blind," and it has occurred to me that perhaps a little light may be thrown upon the cause of failure in so many instances. About thirty years ago, when I commenced house-keeping, I had a garden about 200 feet long, which I planted according to the best of my judgment. Among other things I made several beds of Strawberries. In the month of May an old gentleman called upon me who was an amateur gardener, and famous for the cultivation of Strawberries. Looking at my young beds, his first words were, "Now you must go over these beds, take every plant up which does not show bloom, and throw them all away." Of course I reasoned with him that if they did not bloom that year they would next. "Not at all," said he. "Throw them away, you will have plenty of runners from your blooming plants which will give you fruit, the others never will." Well, I was a young man, and, what does not always occur, I took the advice of the old gentleman in part, and will now give you the result.

All the plants not showing bloom were carefully removed and replanted on each side of the middle walk, about 200 feet long. They were taken great care of, and grew to be splendid plants; but during three years I waited in vain for fruit—they never produced a tea-saucerful, and not one perfect berry.

To test the theory still further I took some of the runners, and found them entirely worthless. Of course I have followed this plan ever since, and have never failed to have a good crop. What I have said refers to Strawberries in the garden; but may not this account for the failure sometimes in pots? I should like some one to test it and report progress. For my own part, I am always careful to take runners for pots from fruit-bearing plants.

Another day, perhaps, if worth your notice, I may give you my little experience in this matter. If what I have written is considered worth a place in your Journal it may bring forth some information upon the subject.—W. Y.

[We shall be much obliged by your relating the results of your experience.]

**THE UNITED HORTICULTURAL SOCIETY.**—This new society held their first show on Tuesday, the 11th inst., in the Albion Hall, Moorgate Street, a building much too confined for the purpose, as there was barely sufficient room to move about between the tables. Elevated at the opposite end of the room to the entrance were Azaleas from Messrs. Lane, and Yuccas, &c., from Mr. Williams, who also contributed *Amaryllis*, *Pandanus reflexus* and *elegantissimus*, and *Hemerocallis Kwanzo flore pleno*. A numerous collection of Azaleas, which was shown on the previous Saturday at the Regent's Park, also came from Messrs. Lane. Mr. Turner, Slough, sent seedling Azalea Duke of Buccleuch, a deep rosy crimson of good substance, and Messrs. Paul and Son, pot Roses and boxes of cut blooms, including among others their new Hybrid Perpetual, Princess Mary of Cambridge, which appeared to much greater advantage on this occasion than at the Regent's Park, the colour being pale rose and pink in the centre. It is prettiest when half expanded. From Mr. Baker, gardener to A. Basset, Esq., Stamford Hill, came very good examples of *Odontoglossum Pescatorei*, *Phalænopsis Schilleriana*, and *Cypripedium villosum*, with eight fine blossoms; whilst Mr. Wilson, gardener to W. Marshall, Esq., Enfield, sent *Phalænopsis grandiflora*, fine, a new *Epidendrum* from New Grenada, with dusky chocolate flowers, and a white lip; *Dendrobium xanthophlebium*, with a white, orange, and red flower;

*Salvia Regla*, and other plants. Mr. Rhodes, Sydenham Park Nursery, had well-bloomed plants of Heaths—Hartzelli major, Profusa, Elegans, and Devoniana; Glendinning and Sons, a nice specimen of *Erica Sindyryana*, cut Camellias, and various Conifers for the decoration of the room; Mr. Aldred, Kilburn, *Anæctochilus*, *Cinerarias*, *Cyclamens*, &c.; Mr. Fraser, Lea Bridge, *Boronia pinnata*, Acacias, *Sphærogyne latifolia*, and *Alocasias*; and Mr. Wheeler, gardener to J. Philpott, Esq., Stamford Hill, miscellaneous flowering and ornamental-foliaged plants, besides which Hyacinths, honey, and some other objects were exhibited. The whole formed a rather gay little show, which, however, was not numerously attended.

### ROYAL HORTICULTURAL SOCIETY'S SHOW.

APRIL 15TH.

THOUGH the Azaleas were somewhat scanty, there was a magnificent display of Roses, both new and old, cut and in pots, whilst miscellaneous flowering and ornamental-foliaged plants, together with *Cinerarias*, were tolerably numerous. In Azaleas Mr. Todman, gardener to R. Hudson, Esq., Clapham, had a first prize for good plants of *Criterion*, *Triumphans*, *Eulalie* (Van Geert), *Coronata*, *The Bride*, white, *Princess Royal*, *Roi Leopold*, *Dr. Livingstone*, and *Princess Mathilde*; and a like award was made to him for a specimen plant of that richly-coloured variety *Duchesse Adelaide de Nassau*.

Roses, however, formed the principal feature of the Show. A single specimen of *President* (Tea), from Mr. W. Paul, was covered with some two dozen expanded blooms, each measuring 5 inches across. For this a first prize was awarded; and the same exhibitor was also first for a collection of nine, consisting of remarkably fine specimens of *Beauty of Waltham*, splendid colour; *Paul Ricaut*; *Charles Lawson*; *Victor Verdier*, magnificent; *Celine Forestier*; *Madame Villermoz*; *Souvenir d'un Ami*; and *Marquise de Foucault*. Messrs. Paul & Son were second, also with fine specimens, among which we remarked *Virginal*, a beautiful white; and *Madame Alfred de Rougemont*, another white Hybrid Perpetual, a section in which there exist too many scarlets and crimson, comparatively with other colours; *President*; *Comtesse de Chabrilant*, and *Victor Verdier*.

New Roses were also shown in numerous collections and in great beauty by both the above exhibitors. Mr. W. Paul taking first, and Messrs. Paul & Son second. Among them were *Madame Victor Verdier* and *Pierre Notting*, the former a very large, rich, bright cherry colour, and the latter a dark violet-shaded red, and both evidently of sterling merit. Among others we noticed *Princess of Lichtenstein*, a new white Hybrid Perpetual; and *Madame Emile Boyau*, a rosy flesh, or blush according to the age of the blooms, and which appears likely to form a good addition to the same class. *Princess of Wales* and *Duke of Wellington* were remarkable for their brilliant colour. Of other kinds the most noticeable were *Amiral La Peyrouse*, *Kate Hausburg*, *Maréchal Souchet*, *Souvenir de Bernardin de St. Pierre*, *Achille Gonod*, *Triomphe de la Terre des Roses*, and *Duchesse de Caylus*. *Princess Mary of Cambridge*, which has been noticed on previous occasions, was again shown by Messrs. Paul & Son, who also contributed several boxes of fine cut blooms of numerous varieties.

*Cinerarias* were not so fine as could have been expected. In addition to the kinds noticed as being the best at the Regent's Park we observed *Adam Bede*, rose self; *Eclipse*, broad rosy crimson edge, with white ring; and *Miss Eyles*, rose, with white ring round the disk. Mr. Lacey, gardener to C. Mortimer, Esq., Morden, was first; Mr. Marcham, Hanwell, second; and Mr. Cox, gardener to Capt. Cabill, Southall, third.

*Auriculas* and *Polyanthus* were shown by Mr. Butcher, Camberwell, who received a second prize for the former, and a third for the latter; and *Pansies*, both in pots and as cut blooms, by Mr. Hooper, Bath. These were seedlings of his own raising. Among them we remarked, *Alexander the Great*, a large white self, and *Delicata*, very pretty. Mr. Hooper, received a first prize for his cut blooms.

Of miscellaneous plants, Messrs. Lee, Hammersmith, contributed *Camellias*, *Azaleas*, the highly ornamental *Acacia*

Drummondii; *Ixora Griffithi*, in fine bloom; *Dendrobium Dayanum*; *Hedera*, &c.; and Mr. Bull, Orange trees, Palms, and Ferns, among which were a fine mass of *Trichomanes radicans*, *Platyserium alcorni*, and some good *Gleichenias*; *Camellias* Countess of Orkney and *La Reine*, both fine white varieties; *Araucaria gracilis*, with pendent shoots; *Dracenas*, &c. A first prize was awarded to Messrs. Lee a second to Mr. Bull.

Mr. Veitch again exhibited his fine new *Rhododendron* Princess Alexandra, *Azalea Stella*, the scarlet-spathed *Anthurium Scherzerianum*, and *Manettia micans*, with long orange scarlet flowers, for each of which he received a first-class certificate; also, *Primula cortusoides grandiflora*, with large, saucer-shaped, drooping flowers, rosy lilac outside, and paler within; and *Primula cortusoides cœrulea*, lilac rose flowers; a first class certificate was awarded to each of these. A white variety was also shown. From Messrs. Smith, of Dulwich, came *Azaleas*, including among others, *Etna*, a fine colour, salmon scarlet and dark crimson spots, a promising variety; *Cineraria Flower of the Day*, purplish plum, with a conspicuous ring of red at the base of the ray florets, surrounding a narrow white ring; from Mr. Cooling, Bath, *Verbena Annie*, of which a coloured plate was given in the "Florist and Pomologist" of February last; from Mr. W. Paul, Beaton's *Geraniums*; from Mr. Beadon, North Stoneham, cut blooms of *Camellias* grown in the open air; from Mr. Bartlett, Lily of the Valley and *Cyclamens*; and from the Society's garden at Chiswick a species of *Peperomia*, with ample foliage, having silvery markings. A few other objects were exhibited, but not of a nature to call for special mention.

#### INTERNATIONAL FRUIT SHOW.

THE challenge which has been given by the Royal Horticultural Society to the gardens of the Sovereigns of Europe, for a competitive exhibition of fruits and vegetables, to be held from the 9th to the 16th of December, has been favourably received by France, Russia, Italy, Turkey, Havover, Greece, Belgium, &c., and further answers are being daily received. The following prizes are offered:—

1. The gold medal of the Society will be awarded for the best collection of fruit and vegetables produced in the garden of a Sovereign.
2. The gold medal of the Society for the best collection of fruit and vegetables grown by any botanic or horticultural society in any part of the world.
3. The gold medal of the Society for the best and most complete representative collection of fruit and vegetables from any of the Colonies.
4. First Banksian gold medal for the best and most complete representative collection from the Presidencies of India.
5. Certificates will be awarded for separate exhibitions of fruits and vegetables, either fresh or preserved, from all parts of the world.
6. The first gold Knightian medal of the Society to the exhibitor who shall obtain the greatest number of first-class certificates.
7. The second gold Knightian medal to the exhibitor who shall obtain the greatest number of second-class certificates.
8. The second gold Banksian medal to the exhibitor who shall obtain the greatest number of third-class certificates.
9. The first gold Banksian medal to the exhibitor who shall gain the greatest number of marks, counting first, second, and third certificates as three, two, and one marks respectively.

#### LAVENDER DISEASE.

ONE of the greatest Lavender growers is anxious about the Lavender malady. Fine healthy plants will begin to die off in pieces, and sometimes altogether, and the stem below ground becomes dark in the centre. I enclose two or three pieces of the head from the same plant, dead and alive. The dead part seems rather floury with mildew, or something of that kind. I think if that is the case, a little powdered lime and charcoal would do good. I firmly believe that the great growers must just go back in their cultivation. For one load of dung used twenty or thirty years ago, I should say that twenty or thirty are used now, and the extreme luxuriance to secure heavy crops may be

the primary cause. The oil of Lavender made on the Continent is not worth a third of that made in this country. The plants in France, are, I believe, still healthy, and as I ascribe the difference in quality to the climate, I have a strong belief that foreign plants grown here would yield the properties of British-grown plants. It is a very serious affair for a man to lose ten or twenty acres of Lavender in full bearing. Can any of your readers give information on this subject?—E. FISH.

#### SIZE OF FLOWER-POTS—CINDERS FOR DRAINAGE.

MAY I suggest to your correspondents that, instead of calling flower-pots 48's, 24's, &c., according to the number in the cast, they should name them according to their size, as four-inch, six-inch, twelve-inch, &c.? Many of the readers of your Journal are not *au fait* in the different sizes of the pots in the casts, besides they vary very much in different parts of England; and as one of the great objects of your paper is to give assistance and easy rules for the guidance of the amateur and those who have not had much practice in gardening, I think every direction as to size of pots, &c., should be as plain as possible. I think every one understands that a six-inch pot is one which averages 6 inches across the top and 6 inches in height.

None of your correspondents have ever to my recollection recommended sifted cinders for the drainage of pots. Charcoal is, I know, often mentioned; but as a rule persons are apt to think that crocks, or broken bricks, tiles, &c., are the only legitimate drainage for pots. Now, for bedding-out plants I always use cinders passed through two riddles—a three-quarter-inch mesh to take out the large, and a half-inch to riddle out the small dust. A few cinders at the bottom of each pot are ample drainage for nearly all bedding-out plants; and when these are turned out to plant, the roots have generally clung to the cinders, which act as a sort of reservoir of moisture for them, and there is no necessity to injure the roots by picking off crocks, but the plants are put in, cinders and all. In large-sized pots a little moss on the top of the cinders is a good addition, in order to prevent the finer soil from washing too much into the drainage. I am rather an advocate for *Verbenas* and *Calceolarias* having nothing as drainage but a little moss. Many plants in April and May in small pots, especially *Calceolarias* and *Verbenas*, suffer more from over-drainage than under-drainage, especially where plants are on raised wooden stages. For large plants which require a good deal of feeding with liquid manure, cinders will be found invaluable, as they act like a sponge, keep the liquid manure in a sweet state, and the rootlets suck the moisture from them by degrees. A mulching of ashes on the top of the soil in the pots helps also very much to deodorize liquid manure.

Many persons think old plants of *Geraniums* flower earlier than spring-struck cuttings. This is contrary to my own experience. Autumn-struck cuttings are always with me the earliest in bloom; then come spring-struck, and old plants last of all. I am speaking, of course, of large old plants which have been cut down and have had to make fresh growth in the spring. Those which were only small plants in autumn and were not cut down or topped when they were taken up are, perhaps, as forward as autumn-struck cuttings; but for all bedding-out purposes no plants are so good as those that have been struck in the autumn, potted off early in January or February, and kept close to the glass till bedding-out time.—X. Y. Z

MESSES. F. & A. SMITH'S DOUBLE CHINESE PRIMROSES.—Having had these in bloom during the past winter (and indeed they are not yet over), I should like to say a word in their favour. They are really most desirable plants, being most profuse bloomers, and very enduring. *Fairy* is a most charming little thing, literally covered with bloom; while *Candidissima* is a pure white; but all are good—an opinion in which I am not singular, as it has been observed to me more than once by those who have largely to do with plants. How excellent they are for winter and spring decoration.—D., Deal.

## CULTURE OF THE GOLDEN ARABIS.

(ARABIS LUCIDA VARIEGATA.)

I THINK it will be readily admitted that all the Arabises are pretty, and have long held the foremost rank for their hardiness and extreme elegance, but this one in particular from its invincible hardiness, alike in the most severe winter and hottest summer. If there is a time at which it looks better than at any other it is in the coldest weather. One great merit it possesses is the extreme facility with which it can be propagated. All you have to do is to prepare a bit of ground, cut down a little old turf, fork this in near the surface, then make your plants into single slips or pipings, place them 3 or 4 inches apart, and in doing this you will scarcely have a bit without a root. If there are any low glass frames at hand to put over the tops of the plants for the first fortnight or three weeks they will grow all the more rapidly.

When planting-out time arrives, which may be any time in the year (of course I do not approve of planting it in the dead of winter), in making ready for planting fork in a little fresh loam and rotten dung, then make your lines as level and straight as for a Box-edging. Never plant it low. After careful trial and experiment the best distance to plant is 10 inches apart and in single lines. Never allow the plants to touch each other by an inch, thus they maintain their natural habit of growth, which is perfectly round, and in height a good two-thirds of a ball. Replant once in two years, or as often as convenient; remove all the flowers as they make their appearance, and any bit that runs to green. By following these simple directions it will be in its full beauty the second year from the slip. Amongst all the bedding or ribbon-border plants it is one of the prettiest, the hardiest, requires the least care, and remains in full beauty all the year round.—T. S., *Mayfield, Falkirk.*

## DEUTZIA CRENATA FLORE PLENO.

THIS beautiful, flowering, deciduous shrub from Japan promises to be as hardy as a Lilac, and seems likely to become more robust in habit than either *D. scabra* or *D. gracilis*, while the flowers are produced in great abundance on small plants. The habit of the plant, however, is more straggling than that of *D. gracilis*, and it is, therefore, not so well adapted for producing a nice compact object for pot culture, but this possibly may be overcome. As a plant to cover a wall it has, I should think, few equals, as the shoots ripen to the points, and mostly flower there. As a new plant it is one of the prettiest in its way we have had for some years, and I trust that it is the forerunner of others equally useful.—J. ROBSON.

## COOL CULTURE OF ORCHIDS.

I WAS pleased to read the very sensible remarks of Mr. Findlay in the last week's Journal on the subject of cool Orchids. That growing Orchids on the cool system, as it is called, is a dangerous experiment there can be no doubt; as there are very many Orchids recommended for greenhouse cultivation which certainly do inhabit very high altitudes, but which, from the different circumstances by which they are surrounded, will, I am sure, refuse to grow well in this country in a greenhouse temperature. I can assure Mr. Findlay the very plants which he selected to experiment on should all be grown in a temperature of from 60° to 80°; but after the growth is fully matured he may gradually subject them to cool treatment until they begin to show flower, after which the temperature must be very gradually increased.

There are many of the choice *Odontoglossums* and other Orchids, which may be grown to advantage in a cooler temperature. There are innumerable Orchids found growing in different parts of the world in about the same mean temperature, but under such widely different circumstances that we might as well try to bring a Melon and a Cabbage to perfection under the same management. As a rule, I have found the Orchids which grow at high elevations in damp and shady situations require much cooler treatment

than those found at the same elevations under opposite circumstances.

In conclusion, I would just observe to those who are about to risk the lives of valuable Orchids in greenhouses, Be careful. No Orchids whatever will bear the draughty and damp temperature your miscellaneous greenhouse plants are subjected to. If you wish to cultivate to perfection what some people call greenhouse Orchids, you must have a house devoted to them, so that you can command a large amount of moisture when the plants require it, which most of them do in their growing season. I may add that the plants of all the most choice and newly imported *Odontoglossums* under my charge here are constantly standing in water, except perhaps when the temperature of the house is under the average, and the night is likely to prove cold.—ROBERT BULLEN, *Gardener, Bow Bridge House, Leicester.*

## MANAGEMENT OF GARDEN IMPLEMENTS.

I WILL anticipate the conclusion our much-respected friend, Mr. F. Chitty, intended, when he commenced his able article on the above subject, by describing the system adopted by me for keeping the implements for garden use, clean and in their proper place; for it is, to quote the late Mr. Chitty's words, "of the utmost importance where neatness and expedition in performing the work of the garden is desired, that the workmen should be supplied with proper tools, and these in good condition; for however true it is that a good workman never finds fault with his tools, it is equally true that any workman whether good, bad, or indifferent, will perform his work better with a good tool than with a bad one."

These words, almost the last written by a thoroughly practical man, should be deeply engraven on the mind of every gardener, for what is there more disgraceful in a gentleman's garden than a disorderly and slovenly tool-shed? It is not only offensive to the eye, but is also a constant and never-ending source of expense to the employer, for tools carelessly thrown about and put away dirty soon become unfit for use, whereas if they are taken proper care of they will last double or treble the time. One of the first things a gardener should do on taking a new situation, should be to see what state the tool-shed is in, and if not in a proper state to have it put in thoroughly efficient order as speedily as possible. The next thing necessary to be done is to procure for each workman a set of tools, which should consist of a spade, rake, Dutch and draw hoes, and one of Parkes's patent digging forks.

But when these are procured for each workman, unless there is some plan adopted to secure the proper management of the tools, they will be of little use; for where there is a set of slovenly workmen, as soon as the clock strikes the hour of 6 P.M., whether the job be finished or not, down goes the tool. It is too much trouble to clean it, and take it to its proper place. Perhaps on the following morning the workman may be sent to a different job, where he will not require the same tool he was using yesterday, so that he takes another tool out with him. Perhaps on the following day he may want the tool or tools he had left out in the wet two days ago; but he has, of course, forgotten where he left them. He knew there was such and such a tool. In vain he makes inquiry first of one man then of another, but all to no purpose, no one knows anything about the missing implement; meanwhile the master is impatiently waiting to show the man what he wants done. Half an hour or more is thus lost; the temper of the master is thereby impaired; sundry locks of hair on the head of the forgetful workman are displaced by the incessant trying to scratch back to his memory where he has left the missing tool, but all to no purpose. At the end of a week or so afterwards he may, perhaps, stumble over it on his way to some fresh job; the tool after lying in the wet and dirt all this time becomes rusty, there is no pleasure then in working with it; but when it is bright and clean the work is performed with greater speed, and done in a workman-like manner, and the cry often heard of, "Master, I want a fresh tool," becomes less frequent.

All this has often come under my notice, and to prevent the recurrence of such disagreeable scenes, and to check

such a wanton waste of my employer's property, I adopted the following plan:—Each workman was provided with a set of tools. They were all had new at once, so that it might be seen which took most care of his tools. Some men will work for months with a tool, doing it but little harm, whilst others will destroy it, or nearly so, in that time. Those who use their tools in such a way should have the difference pointed out to them, by referring to those men whose tools are used properly. This ought to cure them of their carelessness.

After the tool-shed had been properly cleaned, a fresh window, &c., put in, one side was formed into compartments or stalls to keep each man's tools separate. This was done by dividing the space into 2 feet 6 inches stalls, by strips of board 10 inches wide. Holdfasts were driven into the wall to nail the boards to, the strip of boards reaching from the floor above the shed to the bottom; another piece was placed along over the stalls on which the names of the men were written, beginning with the foreman, and ending with the vegetable boy.

A.	B.	C.	D.	E.	F.	G.	H.	I.	J.	K.
2	2	2	2	2	2	2	2	2	2	2
1 1	1 1	1 1	1 1	1 1	1 1	1 1	1 1	1 1	1 1	1 1
0 0	0 0	0 0	0 0	0 0	0 0	0 0	0 0	0 0	0 0	0 0

The spade and fork were hung up against the boards at 00, and large nails were driven into the wall at 2, for hanging the rake on, other nails were driven in at 11, for the hoes. Other stalls were provided for miscellaneous implements, to which all the men have access. When the arrangements were all completed, and the tools all put in their proper places, a notice board was put up, on which were written in large letters the rules I intended should be observed. The notice was to the following effect:—

NOTICE.

All persons not bringing back tools and putting them in their place after using them, will be fined for every such offence one penny. They will also be subject to a further fine of one penny if the tools are brought back dirty.

By Order.

A slate was then hung up in the shed, and the foreman was requested to look over the tools every night after the workmen had gone home, and if any man's tools were missing or dirty, his name was to be put on the slate, which was hung in a conspicuous part of the shed, there to remain till the fine or fines were paid. Sometimes one man would be fined several times in a week, but it soon made them more careful. The fines were all entered in a book kept by the foreman for that purpose, and at the end of the year the money equally divided amongst the men, so that those who have paid but few fines receive the same share as those who have been fined a great number of times. This plan I have found to work well, there is a great saving in tools, and the consolation of having "a place for everything, and having everything in its place."—J. WILLS.

ENTOMOLOGICAL SOCIETY'S MEETING.

The March meeting of the Entomological Society was held on the 6th ult., the President, F. P. Pascoe, Esq., F.L.S., being in the chair. Amongst the donations received since the last meeting was a new volume of the "Linnaea Entomologica," vol. xv., the publication of which has been resumed.

The President announced that, as an inducement to the study of economic entomology, the Council had decided to offer two prizes of the value of five guineas each, to be awarded to the authors of memoirs of sufficient merit, and drawn up from personal observation on the anatomy, economy, or habits of any insect or group of insects especially serviceable or obnoxious to mankind. The memoirs should be illustrated by figures of the insects in their different states, and, if the species be noxious, must detail the results of actual experiment made for the prevention of their attacks, or the destruction of the insects themselves. The memoirs must be sent to the Secretary at No. 12, Bedford Row, London, with fictitious signatures or mottoes, on or before the 31st December, 1865, when they will be referred to a committee to decide upon their merits. Each must be

accompanied by a sealed letter endorsed with the fictitious signature or motto adopted by its author, and enclosing his real name and address. The prize memoirs shall be the property of and will be published by the Society.

Mr. F. Bond exhibited some remarkable Galls found in a large Willow tree near Cambridge, in which the puncture of the insect in the terminal buds of the twigs had resulted in a premature development of the leaves in close whorls, which had remained persistent after the fall of the other leaves, and which had assumed all the appearance and even the colours of a full-blown Rose—a peculiarity which, as it seems most probable, had been the real cause of the supposed mediæval miracle of the leafless Willow trees blooming at Christmas like Roses. Mr. Bond also exhibited two interesting varieties of the common Tortoiseshell and Clouded Yellow Butterflies (*Vanessa Urticae* and *Colias Edusa*), both having dusky blotches in the middle of the fore and hind wings on the upper surface. They had been taken in Suffolk.

Mr. T. W. Wood also exhibited a variety of the Purple Emperor Butterfly, *Apatura Iris*, wanting the ordinary white band on the upper side of the wings. He also exhibited a very rare and beautiful Moth of the genus *Callimorpha* from Brazil.

Professor Westwood called the attention of the meeting to a remarkable memoir just published by Dr. Schiodte, of Copenhagen, in which several new views had been introduced with reference to the principles regulating the primary distribution of Coleopterous insects, and in which he drew a parallel between the merits of Fabricius and Latreille, to the detriment of the latter, as Professor Westwood considered without due judgment; Fabricius having relied in his classification on a single set of characters, whilst Latreille with greater philosophic acumen had seen, that characters which in one group were of primary importance became of secondary value in other groups.

The President also opposed Schiodte's views, as tending to produce very unnatural results in the classification of the insects on which he had been labouring. The President also read a paper, in which he opposed the practice, now daily gaining ground, of overthrowing generic names where they possessed a similarity of sound with other generic names previously established, although differently spelt; and Professor Westwood even ventured to propose that where the same name had been used generically in two distinct classes of animals, or in plants and animals, it was unnecessary to alter it in either division. He also made some observations on the development and economy of the Dog Tick.

Mr. McLachlan read a memoir containing descriptions of all the genera and species of British Caddice Flies.

ON THE UTILISATION OF NIGHT SOIL APART FROM SEWAGE.

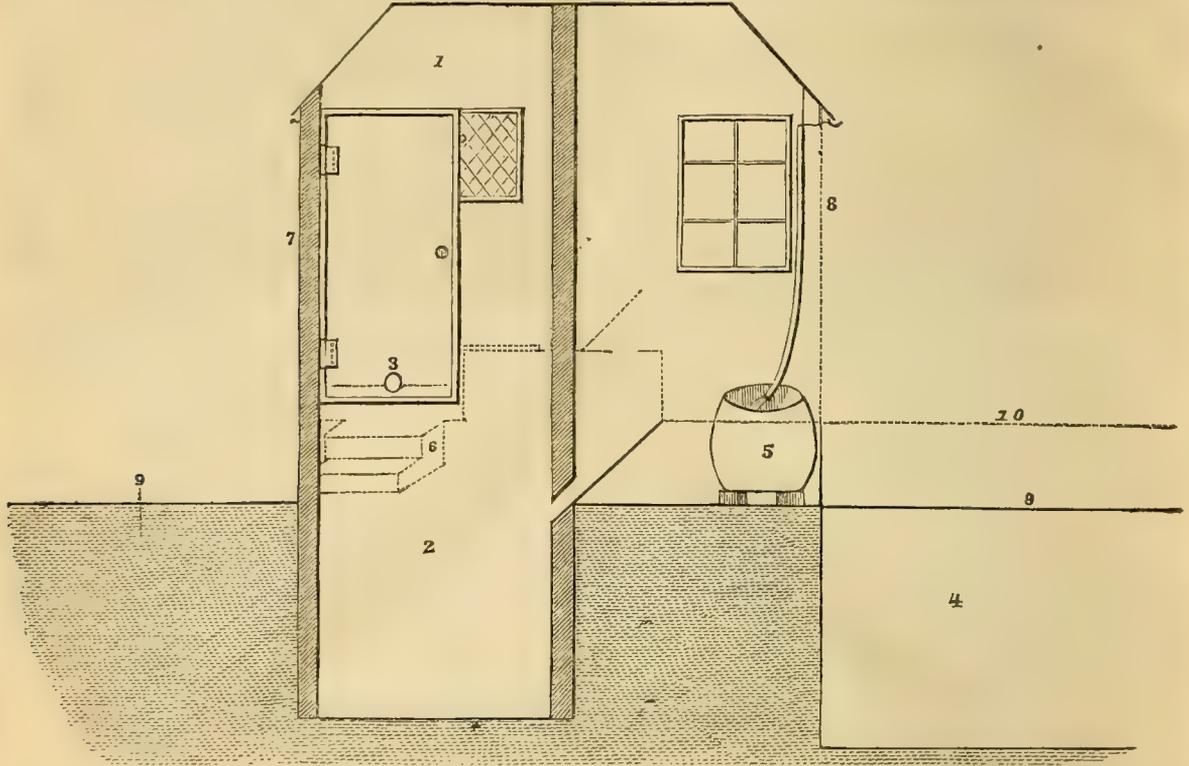

I HAVE been requested to state what I know of the subject set forth in the title of this paper. These words are part of the title of a very useful pamphlet written by E. Wilmot, Esq., J.P., and published by J. Masters & Son, London, at 1d. each, or 8d. per dozen, for distribution. I have long intended to write about the manure in a dry state, but the fear of that monition, "THE JOURNAL OF HORTICULTURE is accustomed to find a place on my drawing-room table," which smote upon a correspondence of our good bee-keeping friends, caused me to halt in my intention. To be sure I might have explained myself in a pamphlet, but I preferred the publicity afforded by the extensive circulation of this periodical. I trust, however, that my diction will not offend, and that I may be allowed to follow out the subject, for it is necessary that these matters should be discussed. Such being the case, I have too good an opinion of the common sense of my countrywomen to think that they will take offence at what conduces to household purity.

Mr. Wilmot prefaces his pamphlet with a letter from Mr. George Thompson, in which he states that a dozen inspectors of nuisances would not overcome the difficulty in Derby. In Woodstock, if I may judge from my own organs of smell, our inspector of nuisances must be in the habit of considering unsavoury odours in an inverse ratio to that which his office dictates. It would have made the pamphlet

more complete if Mr. Thompson had described the "tumbler flushing apparatus" he mentions.

We have had an "earth closet" in use here for some years, though till lately the contumely and prejudice one has had to contend against compelled me to attend to the earthing-over-and-disinfecting-process chiefly myself. I send you an outline descriptive of the structure as being what I consider a model to go upon, a proof that I most cordially agree in the justice of nearly the whole of Mr. Wilmot's remarks, and it cannot be repeated too often, that faecal matter exposed to air or water, gives off noxious and poisonous gases, which disturb the functions of the digestive and respiratory organs, and predispose to disease. Cottagers are not sufficiently well off to purchase disinfectants, and

even if they could, it is generally doubtful whether these compounds do not lessen the value of the natural manures; but simple dry earth, or burnt ashes, can be readily obtained for nothing, and they effectually fix the offensive and poisonous gases, preventing putrefactive fermentation, and absorbing the fertilising elements. Thus, so long as the compost is kept dry the original quality of the manure is maintained; but when it is applied to the land the ammoniacal products are set at liberty, in consequence of the rain, or the moisture of the ground, causing fermentation, and being then in a soluble state they are available as food for plants, which could not have availed themselves of the manure whilst dry. It must be dissolved in water, and it is far better to apply it to the roots of plants than to con-

Scale, a quarter of an inch to a foot.

- 1, The place, measuring 12 feet in length and 6 feet 6 inches in breadth, partitioned into two.
- 2, Watertight earth and faeces-pit, 6 feet deep and 4 feet 6 inches broad.
- 3, The trap-door in the floor of the lower compartment, 3 feet by 2 feet 6 inches, and the drop-ring by which it is raised.
- 4, Compost-pit, where the earth from the faeces-pit is mixed once a-year with other matters.
- 5, The tub which catches the water from the roof, and it is also made to act as a root and lime-water barrel.

- 6, Steps ascending to the lower compartment from the back yard.
- 7, The north end and east side (blank walls) of the place are occupied with Morello Cherries.
- 8, Door entering the higher compartment from the garden terrace.
- 9, Ground-level in yard.
- 10, Ground-level of garden terrace.

A walk branches from the terrace to the doorway, 8; and nearly parallel with this is a stone wall separating the yard from the terrace. Beyond this wall an evergreen shrubbery forms an effectual screen.

taminate the air, or pollute the stream, and so force it through the lungs and into the stomachs of human beings. It is, perhaps, no exaggeration to say that more injury to health is inflicted on the humbler classes, and, in fact, mankind in general, through neglect of the above most necessary precautions, than by any other evil that can be mentioned. All agree that "something ought to be done," but it is of no use finding fault with everybody else for not doing it. The best plan for persons who can see and feel the necessity for action, is to set an example themselves. Ignorance or apathy must give way before such a public example.

In the hottest days of summer I scrape from the surface of the garden some wheelbarrow-loads of dusty soil, pass it through a sieve with a quarter of an inch mesh to exclude the stones, and store it in a disused corn-bin in the stable. An old chamber-pail, with a small hand-coal-scoop, is placed in the lower division of the place, and it is kept replenished with the dry earth ready for distribution.

As we bake at home in a wood oven, a large dredging-box containing wood ashes finds a constant station in the window-sill of the upper compartment, or McDougall's disinfecting powder is made to answer the purpose when the ash is in great request for the garden, or "running ley" for washing. I am no friend to cinders, they are cold hungry things in garden ground, but as we burn a quantity of wood in the grates, I have the mere ash from them sifted, and keep it perfectly dry in a lean-to shed. This dredged amongst growing crops in a dripping time when slugs are troublesome, or when seeds are germinating, is of great benefit. Occasionally the trap door in the lower compartment is lifted off and half a barrow-load or so administered over the entire surface below. It was only the other day that I caught my man applying water to the cinders before sifting them. I knew it was labour in vain for me to explain my chemical reasons for wishing him to act otherwise, so I solved the difficulty, by telling him I would have the powder kept dry. Clay would prove the best of all deodorisers, to

be applied to light soils, both as regards their fertility and texture; but it would require to be spread out and exposed to the action of a winter's frost, and to the scorching effects

of a summer's sun, to reduce it to the state of dry storeable dust.—UPWARDS AND ONWARDS.

(To be continued.)

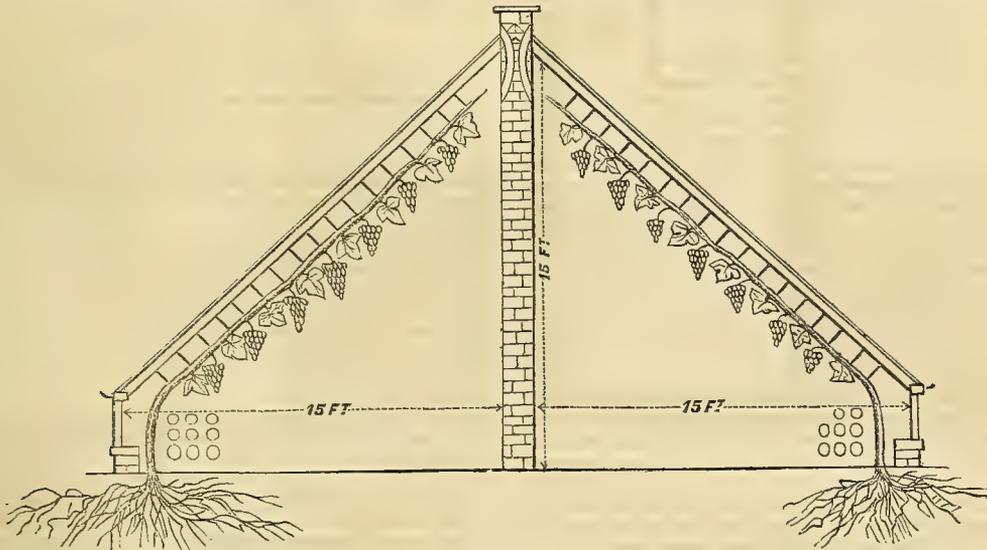

CONSTRUCTION OF A PINE STOVE.—No. 2.

BEFORE writing any more on the shapes and relative forcing powers of hothouses, I should like to say a few words on what I hope will be the tone of the discussion. I have said what sort of a house I am in want of, and have given you a plan. I have also invited a discussion; and should such arise, I hope it may induce you to add a manual on hothouse-building to the long and useful list published at your office.

We occasionally read in the papers devoted to horticulture accounts written *couleur de rose*; and those who bring these accounts down to a practical test are often charged with being discontented persons who cannot see any good in anything. I look upon horticulture from a plain business point of view, believing that it has not reached its culminating point, and that there can be no disadvantage in recognising facts. I am not proposing a manual of opinions; a house of a certain size and shape is a fact; put in it so many rows of pipes, and it must be possible to tell exactly what its powers are, as also if it is fitted for an early forcing-house or not. Early forcing both of fruit and flowers is becoming so common, and the difference between the re-

quirements of winter and summer-houses so great, that I am sure you would be doing good service to many if you would publish such a manual, as it would not only assist those who are intending to build, but also prevent those who have houses from trying what really is impossible. I will give you as an instance the span-roofed house I called in my last plan No. 2, and in which I said it would be impossible to keep up a temperature suitable for ripening Pines in winter. These span-roofed houses have been very fashionable of late for orchard-houses. Let us suppose we have one, and try and deduce from our authorities how many rows of pipes we should require to fit it for Pine-growing.

Mr. Thomson gives us in his valuable book on the Vine, at page 12, the shape of a house which he would recommend, and the number of pipes he thinks would be required to ripen Grapes in April—300 feet of four-inch pipes for a house made in the lean-to shape, 40 feet long and 15 feet wide, the back wall to be 15 feet high. He also recommends that it should have one of his steaming-trays, which he computes as equal to an additional row. I will therefore call the whole eight rows and a half of four-inch piping.

Plan No. 4.

Let us put one of these houses on each side of a wall, as I have shown in plan No. 4, we have thus a house 30 feet wide and 15 feet high, with seventeen rows of pipes. How many more must I add if I take out this centre wall that prevents the wind from blowing through it? and yet a writer told us the other day that eight rows of four-inch pipes were sufficient for a span-roofed house 26 feet wide and 12 feet high! Mr. Thomson says this number is required for his span-roofed houses for summer work, and I think they are not so wide as this. I seek to avoid such a trial in another shape, but know not where to turn to. All pipe heat that is not necessary is obnoxious as well as costly, and as glass and timber are cheaper than bricks and mortar, can we not make up for the loss of this back wall by increase of width and double glazing? This shelter from wind is the first consideration, light second, amount of atmosphere contained the third. I put light second, though this properly speaking includes the gain of heat from sunshine, as in winter it is small. In summer I grant it is the first consideration; but I am looking only to Pine culture, where there are no trellises to consider, and therefore it is included in the amount of atmosphere contained, which in winter

may easily cause great loss, but in summer the larger the more gain. For Pines we only want the largest number of square feet of pit room for the outlay. The square feet of trellis I will not enter upon.—G. H.

[Ever since we gave the description of Mr. Bewley's Fern-house we have lost no chance of advocating double-glazing. We have no doubt that with ventilation suitably attended to, it would be by far the most economical in the end for all houses in which much and regular heat is required. Few gentlemen, however, will as yet consent to let their gardeners go to such a first expense. For fruiting-Pine houses such double glazing would be invaluable; but if not done so securely as to prevent all vapour and dust getting between the two layers of glass, one part of the roof should be in sashes so as to permit of removal and cleaning. Failing this, in cold exposed parts of the country, where fuel is expensive, lean-to roofs will always be desirable, and if walls cost more than wood and glass they are also more lasting. Steep roofs, as shown in Mr. Thomson's early vinery, are also necessary for early forcing, to catch the rays of the sun in winter and early spring. In low-roofed houses, as in low spans, the rays are apt when the sun is low to pass over

the glass instead of going through it. The number of pipes given for a 15-foot-wide house by Mr. Thomson also seems large; but then he has no doubt found out that a first expense for piping was a gain in the end, and a constant saving of fuel, as with such piping it is never required that the water should become so hot as when a less number of feet of piping is used. Although we have not worked anything like that amount of piping ourselves, we have no hesitation in saying that for a hundred feet of piping less there would soon be a greater outlay for fuel, and in proportion to the extra heat given to the piping would be the greater unhealthiness of the enclosed atmosphere. For early forcing mere width will not compensate for a roof, on which the winter's sun exerts most power. We wish our correspondent every success in his attempt to reduce such matters to something like mathematical correctness and decision, but circumstances must ever alter cases.—R. F.]

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

THE regulating of Box and other plants used for edgings to the walks, and for dividing the different quarters of the kitchen garden, having been effected, the gravel-walks should either be turned over or a coat of fresh material added, having previously loosened the old surface. Let the whole be levelled and well rolled, repeating this, particularly after rain, till they become perfectly solid. In reforming them curve them slightly in the middle for rain to pass easily to the sides, but not more than this, unless in very wet situations. The walks being thus set right, and the edgings in proper order, an appearance of neatness and good keeping will pervade the whole. *Capsicums*, replot the plants of the larger varieties intended for turning out next month, harden them off when they have taken fresh root-hold. The small sort, commonly called Chilies, should also be potted in rich soil as they require it, and be kept in a forcing or warm house. *Carrots*, the frames may be removed from the early sowing if required for other purposes; thin and water them as may appear necessary. *Celery*, some of the earliest sowing that has been pricked into boxes may now be planted in a frame; no artificial heat is required, but the light must remain if the weather become cold. Prick-out the successive sowings. *Cucumbers*, constant attention must be paid to stopping and giving air. Add fresh linings and fork them up frequently, which will preserve a moderate heat in the beds for some time, and will render a large quantity of fresh dung unnecessary at any one time. *Dwarf Kidney Beans*, make a sowing on a south border for the first crop. *Lettuces*, forward the spring-sown plants where there is a scarcity of the autumn-sown ones; water them in dry weather, and keep the soil about them loosened. *Peas*, earth-up and stick the advancing crops; before earthing use soot for the purposes we have before recommended. *Radishes*, make a sowing of the Turnip-rooted kinds; water those in frames when dry. *Rhubarb*, seed should now be sown to produce roots for forcing.

### FRUIT GARDEN.

In the case of several of our cultivated fruit trees experience has abundantly proved that the removal at an early stage of their growth of shoots, which from the adoption of a system of training, or a tendency in the tree to excessive luxuriance, are deemed superfluous, is both advantageous to the health of the tree and favourable to the production of handsome fruit. Pruning may effect the result desired, but it is a violent remedy, although necessary in some degree. Disbudding, properly speaking, is the art of preventing the development of useless buds at the expense of those which should be preserved, as it must be more advantageous to check an unnecessary shoot at an early stage than to wait until it has exhausted the tree of a greater or less quantity of sap. It is, then, not generally advisable to wait until a badly-placed shoot is developed, but to suppress it early. With Apples and Pears peculiar judgment and discrimination are necessary, and stopping should be systematically practised. The excess of shoots produced by Peach trees invites the practice we recommend. The same attention should be directed to Vines.

### FLOWER GARDEN.

Here too much unnecessary growth may be prevented. Roses, for example, if judiciously disbudded, not only bloom better, but form finer and more vigorous plants. Where the possessors of gardens can enjoy their country seats, during the months of March, April, and May, it becomes an important matter to provide abundance of very early spring flowers, for the floral appetite is generally of an active character after a long and severe winter. The early-flowering bulbs are too well known to need notice here. There are, however, a few old-fashioned plants which should never be lost sight of, and which should greet the returning spring from every nook and corner. Of such things are the following:—The blue and white Squills, the *Sisyrinchiums*, the Dog's-tooth Violets, the *Pulmonarias*, the *Omphalodes verna*, the *Arabis* and *Aubrietias*, the various *Primulas*, with self *Auriculas*, and the lovely little *Sanguinaria canadensis*, not forgetting the old Christmas Rose, which forms, as it were, the connecting link between the expiring year and its successor. The *Colchicums*, autumn *Cyclamens*, and Winter *Aconite* have duly ushered it in. Such should be much more encouraged than they have been, for they must ever be favourites with the many. Among shrubs, too, the *Cornus mascula*, the *Mezereon*, the *Cydonia japonica*, the *Chimonanthus fragrans*, the *Ribes*, *Corchorus*, &c., should be much encouraged. Stocks, as a matter of course, will always be grown, and we recommend a trial of the *Chrysanthemum*-flowered *Asters*, which have bright and distinct colours for beds, with the advantage of having erect flowers. Do not forget to make one or two sowings of Sweet Peas, to keep up a succession of bloom.

### GREENHOUSE AND CONSERVATORY.

Camellias making wood should have occasional shading; keep a moist atmosphere about them day and night, or they will grow gawky and long-jointed; a temperature of 55° at night and 65° by day should be maintained. Let all *Pelargoniums*, *Calceolarias*, *Cinerarias*, &c., be well staked out in due time, removing inferior plants, or those of a successive character, to any of the ordinary plant-structures. *Kalosanthes* will require neatly tying-out, as these plants form beautiful globular-shaped specimens by a little management. *Fuchsias* will require a second shift, which should now be into their blooming-pots, using a light rich soil for the purpose. The same will suit *Scarlet Geraniums* growing for specimens. At this busy season there is great danger of neglecting winter-blooming plants, such as *Epacris*, *Daphnes*, &c.; but if these are to be had in anything like perfection next season, they must be properly cared for now. Show-houses are generally kept too close and warm for *Epacris* and *Heaths*, and in that case they should be removed to the greenhouse as soon as they are out of flower, affording them a rather damp and shady situation for a few weeks. While drying winds and bright sunshine prevail, considerable attention will be necessary to maintain a moist healthy atmosphere in the conservatory, and no effort necessary to secure this should be spared; for it is hopeless to expect flowers to last in a dry warm atmosphere. A thin shade should be used to break the force of the sun, and in giving air every care should be taken to avoid drying currents, opening the top ventilators only, as long as these will suffice to prevent too high a temperature; and every available surface of bed or border should be kept constantly moist, in order to secure plenty of evaporation to counteract the drying effects of the external atmosphere.

### STOVE.

Make cuttings of stove stock. Do not forget the old *Vincas*, the *Thunbergias*, *Plumbagos*, *Justicias*, &c. These, though old-fashioned, contribute much to the general effect. The *Orchids* are now progressing fast, and will require attention in shading daily, and gradually increasing the humidity of the house, so as to keep pace with the increase of solar light and heat. If the roof is covered with creepers, a little management in training them, to effect a judicious shading of the plants beneath, will save much trouble, and add much to the appearance of the house. See that plants on blocks, or suspended in baskets, are not allowed to get dry. Watch for and keep down insects. Plants in bloom should be removed to a house with a drier atmosphere, to prolong their period of flowering.

## PITS AND FRAMES.

These will want not only daily but hourly attention; propagating, pricking-out, potting, hardening-off, with shading, syringing, &c., will be the order of the day.—W. KEANE.

## DOINGS OF THE LAST WEEK.

## KITCHEN GARDEN.

WHAT a week of July weather in the beginning of April! The notes of the birds in the early morning made us almost forget their depredations of the past. We could almost forgive the defying challenges of pheasants and partridges, as they rooted up and nipped the tops of Peas before we were out of bed; but telling us emphatically that we must rise with them, if we would interfere with their pilfering. They will do but little harm now, and to make amends we must sow a little thicker, even if we thin out afterwards. It is very different as respects sowing Peas and Beans late in autumn. What with birds and vermin of all kinds, there is little security for them unless protected with wire netting. This and the annoyance of hunting after slugs, &c., has made us altogether give up autumn sowing, and we sow instead under a little protection in spring, and then transplant. Those turned out of turves the other week are pricking up nicely in this splendid weather, looking as if they were grateful and pleased at the attention they received, and telling of their wish to yield us early gatherings as a reward for our care. The first out-door sowings are now up. Sowed another succession of Veitch's Perfection, Jeyes' Conqueror, or Ne Plus Ultra, and Harrison's Perfection. The last makes no show on the table for size like the first two, but it is a fine cropper, and a most delicious sweet little Pea. For general work see last week.

Sowed the main crop of Borecoles, Broccolis, Savoys, and will prick off some of those sown earlier, for the first crops. Watered Cauliflower that had been planted from hand-lights and cold frames, and gave also a fair watering to a quarter of Cabbages, as we were apprehensive that the hot, dry weather would cause the youngest or latest part at least to bolt, and show their flower-stems. Gave abundance of air or full exposure to Potatoes, Radishes, Lettuces, &c., under protection. Hoed among Lettuces out of doors, and gave a little water. Hoed among all growing crops, and also the Asparagus quarter, in order that all might be clean before the shoots appeared. Sowed Asparagus and Sea-kale, some of the latter in rows, to remain there, some thickly in a bed to be transplanted afterwards. Planted out Asparagus rather earlier than usual. The ground had been well trenched and enriched, and small drills were made 2 feet apart, and the plants spread out about 6 inches apart in the row, watered and covered over with the earth between the rows, thus making a little ridge. A little dung was thrown over the ridge, and some burnt clay and rubbish over all. For some seasons a light crop, as Lettuces, may be taken in summer between the rows. We rather like this mode better than beds, especially when taking up for forcing is concerned. A friend of ours has just been sowing some in rows where it is to stand, and as he has plenty of ground, we have no doubt the plants will answer admirably. The ground had been well stirred and enriched. It was then thrown into blunt ridges 4 feet apart. The ridge was then opened up, so as to form a shallow trench, and this was filled with rotten dung to a depth of at least 4 inches. A little soil was thrown on the dung, the seeds sown, and then a little more added as covering. The rows will thus be 4 feet apart. He wants it strong for forcing in four or five years, and we have no doubt the plan will succeed. The space in the hollows will be cropped slightly in summer.

## FRUIT GARDEN.

Went on with nailing, and finishing pruning out of doors. Covered Peaches and Apricots thinly with laurel twigs. The orchard-houses are now a picture—the blossom strong and healthy, and no signs of an insect of any kind as yet. The fruit seems setting too quickly, helped, perhaps, rather much by the bees in search of pollen. In these scorching days we thought it advisable to just colour a little water with whitening, and syringe the outside of the glass with it,

which diminished a little the force of the sun's rays. Air has been given night and day in general, but in reduced quantity at night. Care was taken, however, to give all the air possible early in the morning, and then the houses, even with large squares of glass, never became unbearably hot in the day. The thermometer at night for the past week ranged from 40° to 45°, and onwards up to 85°, and even 90° during midday. Such heat does no harm when there is no condensed vapour, and the heat rises gradually. We have been privileged with several private notes of failures, the blossoms falling, shrivelled up, &c. In all these cases want of early air-giving was the cause. If in these bright mornings people do not think of looking to a house shut up the previous night until between eight and nine in the morning, they must take the consequences, especially with such trees as Peaches in bloom, and the house facing south or south-east. It would be much safer to leave air on all night. Better risk a little frost than a downright scorch. In the lateinery, now filled with Pelargoniums and bedding stuff, the Vines are breaking, and to keep them from becoming too forward, when we must keep them going, we threw a little whitened water over the roof, and in this fine weather gave air all night.

Took the most of the things out of the Fig-house or pit, and watered with manure water, intending to soak them well, not at once, but at three times, with a few days interval between. Observed the same plan with Peach trees against the wall in the orchard-house. Watered the ground about 2½ feet wide, then in about another week will do as much more, and so on. When such trees become dry in winter, and are soaked all at once, the buds and young fruit are apt to be thrown off. All such operations should tell gradually. Thinned Grapes in the earliestinery. In such fine weather allowed the temperature to fall to about 60° at night, and after giving air at back early in the morning, gave no more air, if the heat from the sun did not rise above 85° or 90°. Of course, in such sunny days it would be mere waste to have sun heat and fire heat combined, so that the week of bright weather has been a good saving to the coal-heap. Regulated Strawberries now bearing nicely, and potted Melons, &c., for beds and pits. We would now notice three things.

1. *Insects*.—Like some other friends, our good instructor, Mr. Rivers, has rather read us wrong. We have old houses and old walls, but, on the whole, we are not so troubled with insects. We used about 1 oz. of tobacco for smoking some Cucumber plants on Tuesday night, the first smoking we have given for the season. We were but little troubled with the brown aphid last season, but we were not free from it entirely. We think prevention, if possible, is better than cure, and notwithstanding our care in this way, this aphid has appeared twice or thrice in our Peach-house this season. Of course, it was never allowed to multiply. But for chronicling our doings just as they happen, we might not have spoken of such a thing at all. We believe we are indebted to Mr. Rivers for the mention of quassia water. At any rate it is a clean remedy, even by itself, for this insect, and, perhaps, is more effectual. In fact, we believe it is, when boiled, as advised at page 287, with water and soft soap. But the insect is very easily destroyed; even the least touch with the fingers settles it. The mischief is, that if one or two escape your fingers and brush, you will have them like ropes of Onions in a few days, if you only let them alone. As yet they have troubled us but little, but we wanted to let others know to be on the look-out. Until about three years ago we never knew the pest, and we should have been glad if we had never seen it. As already stated, we look upon this brown aphid as king and governor, not because he is difficult to kill, but because the increase of generations is so rapid. The man who sees one will stand in his own light if he wait to see half a dozen.

As an evidence that we are not so troubled with insects, we may mention that nothing else except these few brown aphides have appeared in the above Peach-house, although, from shortly after the gathering of the fruit last season, it has been constantly in use for something, and a system of tier upon tier, and of filling and cramming has been resorted to, such as is seldom found in nurseries. Gardeners often bring much of this on themselves, but when once involved in it cannot easily get out of it. The house is a lean-to,

about 10½ feet wide. During winter the shelves, floor, and temporary stage beneath the trellis were filled with bedding plants. These were removed, and plants needing a little heat introduced, and now these are being removed to make way for others. At present, besides these temporary occupants, there are four rows of Strawberries the full length of the house, some ripening, others swelling, and some in bloom; and with all these varieties there has been no necessity for using even a puff of tobacco. The Cucumbers, the other night, and a few pots of Verbenas that had a little fly, are as yet the only plants, since last autumn, that have ever been smoked. Though this is the case, we are none the less obliged to Mr. Rivers, and to his mention again of the quassia water. We recommend it especially to ladies, for using to Roses, &c., with a brush with a longish handle, as it is so cleanly, and a little practice will prevent any dropping on their gloves or garments.

But for being behind with our work, we should have trespassed on Mr. Rivers to see his Apricots in pots, as with them we have as yet done little, and would like to have a fair start. As stated several times, we have no objection whatever to the pot system, except the watering, when water is scarce. We believe we are only beginning that system, and that the time will come when much smaller plants and pots will be used, in order that the plants in full bearing may stand in ornamental vases on the dining-table, when, of course, pots will be used to suit the vases. The taking such plants to the table with the pots mossed or tied round with ornamental paper, will ever be miserable attempts at refined taste.

2. *Birds.*—We have tried white worsted and black worsted, white, black, and red cotton, and, like windmills and guys, they all do good for a time; but then the birds soon become used to them. We have seen the roguish tom tit, and the impudent sparrow, if the thread was strong enough, sitting on it and swinging backwards and forwards in high glee, like a parrot on its swing perch. However, all these means, though not giving security with us, act as preventives, and notwithstanding all our outcry, if now let alone we will be pretty well for the small fruit. The Gooseberries are now so green as to be very nearly out of danger. Our opinion is, that we have had more benefit this season from syringing the bushes with a mixture of cowdung, soot, and lime, so as to make the buds unsavory. When that is mixed thin in a tub, and the operator puts on an old sack, or a mat tied round him, and uses the nozzle end of an old syringe, regulating the discharge with his hand, he will go over a great breadth in a short time. However, we advise all those who may abhor such work, to try the thread method, which will be effectual as a deterrent until the birds become used to it. Since the fine weather set in, the birds have troubled us but little. If they would be content with their share, anything and everything, and any mode of frightening them, are better than killing them, as no doubt they do us good, when they neither pilfer buds nor fruit, and there is something quite out of character in the report of guns amid the quiet that should be associated with the garden.

3. *Boilers and their Position.*—As coming in our way, we may state that boilers should be set quite free of the place to be heated by them, and so that they can be examined without interfering with the chimney that takes off the products of combustion. When houses, or a series of pits are to be heated, and the fire is intended to play not only on the inside but over the whole of the outside of the boiler, it is often deemed economical to thrust a part, if not the whole, of the boiler thus to be covered over inside of the houses or pits to be heated. It would often be truer economy to have such a boiler wholly outside, and so that the whole could be easily examined without interfering with the house, chimney, &c. We have a boiler so placed, fully one-half inside of a pit, the boiler heating three pits. About three years ago, after working some fifteen years, one of the sides—that farthest from the chimney, and next the flue—gave way. To reach it we were forced to open the flue outside, and also to sacrifice the crop in the first division of the pit, so as to get down to the boiler. We then, as we detailed, squeezed in an iron plate, which has stood ever since. Last week the other side gave way, the water pouring out about the centre of the side. This side we were anxious to reach

from the outside; but then there was the chimney at that side, and then a four-inch return-pipe stood right in our way. We could easily have reached it from the inside of the pit by removing earth, clinkers, and brickwork; but then we knew that our Cucumbers in bearing, and Vines in bloom, would be destroyed, or much injured. We therefore gave up the idea of plating the side of the boiler, as we could not reach it without breaking a hole inside; and as pulling out the boiler was not to be thought of, with so many tender things in the three pits depending on it, we merely cleaned out the flue on that side, damped it well, and filled it as high with wet bricks and Portland cement as went considerably above the leakage in the boiler. These bricks had to be shoved along and fastened and levelled with a long-handled spatula, the bricks and cement being squeezed up to the side of the boiler. As far as we recollect, we used about three courses of brick-on-bed. This still left a good portion of the side of the boiler exposed. As a temporary measure it has answered admirably, the rapid leakage being quite stopped, though of course the fire will not have quite the same effect on the outside of the boiler. We would have had little faith in the cement if the heated air passed below it, but it may stand a long time with the heated air passing above it. When the heat of summer comes, means must be used for setting a fresh boiler. The want of a boiler in such weather as we had a fortnight ago would have been ruinous, and any temporary tinkering to insure its working was an object to be aimed at. After emptying the boiler, all the bricking, &c., was done in a few hours. Our object in thus relating the misadventure is simply to state our conviction that, if the boiler had stood in the stoke-hole, and not mostly in the pit, we could have uncovered its side, and jammed against it a piece of plate-iron covered with red lead, in much less time, and we would have had more faith in the iron than in the bricks and cement. We could not get at the side without destroying the Cucumbers in the pit.

Though, as a matter of caution, and to show that something may be done in an extremity, we thus mention about this boiler, we do not wish it to be inferred that we are always in trouble about boilers. In a quarter of a century we have certainly replaced one, and we have tinkered this pit one, which should be replaced this summer. There are old boilers here, old when they came under our care, and likely to continue in working order, as far as we can judge, so that however old-fashioned they are, they so far answer the purpose. Such misadventures as the above, too, whilst they do nothing to disprove the economy of the large single-boiler theory, show the importance of having another boiler to act in a case of emergency. Imagine a single boiler that alone heats some dozen forcing-houses and plant-houses, giving way in such weather as we had in 1860 and 1861! We may also mention, that without any great leaning to the material of boilers, most of the failures we have met with and known, took place with wrought-iron boilers.

#### ORNAMENTAL DEPARTMENT.

Much the same as last week, cutting edges, rolling, digging, pruning, and potting, inserting cuttings, and turning out great quantities of bedding plants into temporary beds, where they can be protected until after the middle of May. On nothing as yet have we discovered an insect. The word protected, above noticed, must be kept in mind, for we cannot expect this weather to last, and there may yet be cold winds and sharp frosts before the 20th of May. Some are already complaining that their plants have been much injured by the strong sun; but all sudden changes must be avoided or neutralised. Plants are just like children, they seem to know and show gratitude to those who love them, and enter into all their little wants and wishes. There may be the strictest attention and duty so called, but these will never insure the growths and results of kind affectionate interest.—R. F.

#### TRADE CATALOGUES RECEIVED.

J. Scott, Merriott Nurseries, Crewkerne, Somersetshire.—*Descriptive Catalogue of Bedding Plants.*

Butler & McCulloch, Covent Garden Market, London.—*Price List of Agricultural Seeds.* March, 1865.

COVENT GARDEN MARKET.—APRIL 15.

In consequence of the change in the weather during the past week, the market is more plentifully supplied, and prices have become proportionably lower.

TO CORRESPONDENTS.

We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

Books (*John Barker*).—The "Rose Garden" by Mr. William Paul. You can obtain it from our office. (*T. Mitchell*).—"How to Farm Two Acres," by Mr. Robson.

CLIPPING BOX-EDGING (*E. D. Bangor*).—The recommendation to cut the Box-edging in June was quite correct. The cause of the leaves becoming brown was most probably the long-continued dry weather, and perhaps, also, the exhaustion of the soil. Clipping should be done in moist weather. Any browned portions may be removed now, or, if necessary, the edging clipped.

DOUBLE CHINESE PRIMULAS (*A Subscriber*).—They are obtained from seed, or the single varieties sport in double varieties. Seed of double Primulas cannot be purchased, and you cannot obtain them from seed except by accident.

TREATMENT OF VINES BREAKING (*A Subscriber*).—The Vines now breaking should be sprinkled twice daily with aired water, and be allowed to come on naturally with sun heat, employing no fire except on frosty nights. The reason of the bunches going off into tendrils is probably due to the roots being in a badly-drained border, and situated at a great depth, where they are deprived of air, and form few fibres; the result is long gross wood, which it is hardly possible to ripen properly. By keeping the house warmer than usual you will only increase the evil, by causing the leaves to demand more food than the roots in a cold outside border are calculated to supply. You will do best to reserve the warmth for ripening the wood in autumn, too much heat being likely to cause the production of tendrils bunches, or bunches of fruit formed in embryo in the previous autumn.

DESTROYING CHICKWEED (*H. B.*).—The best way to destroy it is never to allow it to seed, hand-weeding, or cutting it up before it seeds. It will then disappear, or cause but little trouble, though the ground will always be liable to it. Covering with fresh soil would be a means of keeping it under, but the old soil must be covered so deeply as not to be brought to the surface.

SPRINGING PEACH AND NECTARINE TREES (*A. P.*).—Early in the morning if the weather is mild, and again at three or four o'clock in the afternoon. This had better not be done till after the fruit is set. Tobacco water should be used once a-week to keep down green fly. The Thames water would be the better of standing a few hours in tubs or cisterns.

SPRINGING CAMELLIAS AND AZALEAS (*Idem*).—Springs twice a-day before and after they flower, but neither should be syringed whilst they are in flower. Morning and evening are the best times, but they should be syringed early in the morning in order that the foliage may be dry before the sun comes out very strong on them, to prevent burning. Tan will not produce heat enough for Cucumbers and Melons. Stable manure is much better.

COVERING A CHIMNEY (*H. S. C.*).—Procure a packet of mixed *Trapaesium* seed; sow at once at the base of the chimney in good soil.

GARDENER'S HAVING TO FIND CANDLES (*A Foreman*).—The allowing of candles for a bottle, and for looking after fires, is merely a matter of private arrangement. Candles, or a trifle instead, are very often allowed for the latter purpose, as no houses can be well attended to in winter without lights to see the thermometers and stove-holes, and also feel the heating medium, which is of more importance than looking at a glass. 19s., however, seems a deal of candle to be used for such a purpose in a winter. We should have been glad if, having received the concurrence of the head gardener, the gentleman had seen proper to make you some allowance. It is impossible to establish anything like a rule in such matters. We can only say, in conclusion, that if all the facts are as stated, we think that some allowance should have been made to you, unless there was any understanding to the contrary, but that it is best when such matters are stated in the engagement, and when all such allowances are merged in wages. You cannot, however, demand anything of the sort; and our earnest advice to you is that, so long as you continue in the situation, you will not abate in the least your anxious attention to all under your charge.

TWELVE VERBENAS FOR EXHIBITION (*J. Choyle*).—Brillant de Vaise, scarlet shaded; Fairest of the Fair, white, purple eye; Foxhunter, scarlet; L'Avenir de Ballent, pink, rich crimson centre; La Grande Boule de Neige, white; Magnificens, large rosy lilac; Faast, rosy scarlet; Peep o' Day, rosy salmon; Ruby Ring, bright ruby; Warrior, rosy pink; Zampa, purple; Blue Beard, blue.

SEVERE DWARF DANCIAS (*A Subscriber*).—For a border 3½ feet wide you could either have one row of dwarf Dancias with an edging, or two rows without an edging, or a small one. The plants should be about 13 inches apart. The following are good kinds:—Zelinda, purple; ditto, yellow; Tom Thamb, maroon; Titian, yellow; Snowflake, white; Alba Multiflora, white; Prince Arthur, bright crimson; Dwarf Queen, purple, white tipped, and many more. A row of purple, and then a row of white, would look well, and so would purple and yellow. These are from 13 to 24 inches in height.

PEACH BLOOMS FALLING OFF (*An Old Subscriber*).—The Peach trees very likely suffered from one of two extremes—perhaps they had not sufficient water before they commenced swelling their buds, or they may have had too much; but the back wall of a vinery is a very bad place for a Peach tree. If the south front of the vinery is covered with Vines, it would be impossible for the Peach trees to obtain sufficient sun and air for ripening their wood; and even if they did the variations of temperature required for the successful cultivation of the Peach would be death to the Vine. If they were both started into growth at the same time, perhaps at the time the Vines would require a temperature of 75° or 80°, the crop of Peaches would be sacrificed if the trees were subjected to a higher temperature than 55°. Want of attention to the fertilising of the blooms is no doubt the cause of the blooms dropping off in many cases; but we do not consider this to be the cause of your trees shedding their blooms. The best plan, we find, to disperse the pollen, is to have a piece of thin board, and well fan the trees with it several times daily when they are in bloom. This should be done, if possible, while the sun is shining. There should be as much air as possible on at the time of the operation. We seldom find any difficulty in setting the fruit well in this way, providing the wood has been well ripened during the previous summer.

SUMMER PRUNING APPLES, PEARS, &c. (*J. Parker*).—The best time to perform this operation is about midsummer. The branches should not be cut short, only just the points nipped out, but shoots that will not be required may be cut clean out; if you desire to have the trees covered with short fruiting spurs, the tops should be nipped out three or four times during the summer, commencing as soon as the shoots are 3 or 4 inches long. For Gooseberries or Currants the branches should be cut clean out from the centre of the bushes, so that the air may pass freely through them. The shoots left on them should be cut back to about 13 inches or 2 feet.

FIGS DROPPING PREMATURELY (*B. B.*).—The most likely cause of the fruit falling or turning yellow is the extreme variability of the temperature which you maintain. 90° is a high temperature, though even that would do no harm if it were chiefly from sun heat, and were accompanied by abundant ventilation. We think that the trees have been brought on too quickly, and that the temperature has been too high one day and too low the next—in short not regular enough, and not only too hot at times, but also very moist. Stopping the shoots under these circumstances would not prevent the fruit falling, though the points should be pinched out above the fifth leaf. Perhaps the soil has not been kept regularly moist, it being a very nice point to water Figs. They must be well and regularly supplied with water. If the trees were fresh potted that would tend to make the fruit fall, and watering with cold water is a frequent cause of the fruit falling prematurely. If the roof is too much shaded by the Vines then the wood would not be sufficiently ripened in the previous year, and that too would cause the young fruit to fall. Though these are some of the probable causes of the fruit falling, we are not sure that any of them apply to your case, the Fig being liable to cast its fruit, to a certain extent, under the best known treatment. The Figs not fallen or not turned yellow will, in all probability, ripen off and be very fine, as we have usually found them on trees exceedingly vigorous, the second crop being both abundant and excellent. Keep well supplied with water, and we think you will have a good second crop.

CULTURE OF CAMELLIA-FLOWERED BALSAMS (*C. W. W.*).—Smith's are the best; procure the seed at once, sow it in a gentle hotbed. As soon as the plants are up prick them off into small pots. Keep them as near the glass as possible; as soon as they have well filled the pots with roots give them a shift into 43 or 32-sized pots. As the plants gain strength give them as much air as possible, and as soon as they have well-filled their pots with roots, go on shifting them into still larger pots until you get them into No. 1-sized pots. They must have as much light and air as possible, and be kept free from green fly, and all the blooms should be picked out as they appear, until they have their final shift. A good strong loam and well-decomposed cow manure is best for them. After they have had their final shift and the pots are well-filled with roots, give them copious waterings with liquid manure three or four times a-week. You cannot over-feed them after they have had their final shift.

MULBERRY TREE IN POT (*A Clerical Subscriber*).—Treat it the same as you would a Fig, by pinching at every fourth or fifth joint. It must not have too much pot room, otherwise it will soon grow too large for your greenhouse. If you treat it in this way it will require but little winter pruning.

**FLOWER-GARDEN PLANTING (B. F.).**—We think your planting will do very well, except that the Roses will not stand like the others; and the whole would have told better if you had had a centre clump. (F. L.).—Send the plan of your garden, with the arrangement which you propose, and we will comment upon it.

**BEST CUCUMBER FOR OPEN GROUND (R. M.).**—Henderson's A. L. Ridge Cucumber.

**NAME OF FRUIT (B. A. K. P.).**—Easter Beurré.

**NAMES OF PLANTS (C. P.).**—*Bartramia pomiformis*. (A Subscriber).—1. *Didymodon heteromallum* (?); 2. *D. purpureum*; 3. *Jangermannia bidentata*; 4. *Dicranum scoparium*; 5. *Trichostomum aculeare*; 6. *Hypnum cupressiforme*; 7. *H. striatum*; 8. *Dicranum scoparium*; 9. *Hypnum rutabulum* (?); 10. *Gymnostomum pyriforme*; 11. *Marchantia sp.*; 12. *Hypnum splendens*. (C. P.).—*Asplenium cicutarium*. (F. D., *Pershore*).—*Lastrea decomposita*. Clip down the Fern with a pair of scissors.

### METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending April 15th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.

### POULTRY, BEE, and HOUSEHOLD CHRONICLE.

#### APPOINTMENT OF POULTRY CLUB JUDGES.

"LOOKER-ON" in his letter of March 7th says that there is an exhibitor, an extensive dealer, who, according to his own advertisement, has taken 537 prizes, including eleven silver cups, since January, 1864. "I am not the only one," says "LOOKER-ON," "who has made remarks about the success which appears to cling to members of the Club when their own judges are officiating." Now the inference, as I take it, which "LOOKER-ON" wishes your readers to draw from this is, that these prizes have been influenced through my being a steward of the Poultry Club. For "LOOKER-ON's" information allow me to say that the number of prizes I have taken under the nominees of the Club since the commencement of my stewardship does not exceed twenty. I leave your readers to draw their own conclusions from the two statements. "LOOKER-ON" objects to my holding the office of steward on account, as he says, of my being a dealer. That I sell a large quantity of poultry I will not attempt to deny, but I am no more a dealer than any other exhibitor who advertises his birds through the columns of your Journal! I have a business independent of this, which so far has been found sufficient for my wants; but exhibiting and keeping poultry is a hobby in which I take a great delight, and I endeavour to make them pay as well as possible, and I have yet to learn that there is anything wrong in this. "LOOKER-ON" thinks if I do not resign my office ill-natured persons will say that the reason I am so successful is because I am one of those who appoint the judges. Well, if ill-natured persons only say this I shall not much care if I can only retain the good opinion of the good-natured and the just. "LOOKER-ON" must excuse me if I decline to act upon his advice. By the unanimous vote of the members of the Club at their annual meeting I was elected a steward, and I think should ill-require the confidence they have placed in me were I to resign office.

With respect to the exclusion of dealers as judges, I had nothing to do with framing that rule. I would exclude no class provided they were men of ability and undoubted integrity, and I doubt not there are many such amongst dealers. I have the rules of the Club now before me, and can find no exclusion rule—it appears to have been rescinded. I feel rather astonished at "LOOKER-ON's" objection to my showing in Miss E. Beldon's name: what harm does it do him or any one? Even "LOOKER-ON" is at a loss to understand for what object I do it, still he thinks it an additional reason for my resigning office. He must show me some better reason before I act upon his advice. The ridiculous practice, as he calls it, I shall retain so long as it pleases me, and Miss E. Beldon. "LOOKER-ON" by his own statement appears to have been an unsuccessful man in the exhibiting line, and seems to have no sympathy with one who happens to have been more successful than himself.—H. BELDON.

### THE BATH AND WEST OF ENGLAND POULTRY SHOW SCHEDULE.

It is not pleasant to have to find fault when one meets with such a liberal prize list as this; but I must say one word about the Bantam prizes. What can the Committee be thinking about to offer first and second prizes for Gold-laced Bantams, for Silver-laced Bantams, and for Black and White Bantams, and leave the favourite Game Bantam to compete in the Any other variety class?

Can the Committee be ignorant of the fact, that at Birmingham no less than one hundred pens of Game Bantams, not counting single cocks, were entered, and that the entries of Gold and Silver Sebrights, and Black and White Bantams together, only mustered fifty—less than half? But that is not the worst aspect of the case; in the Any other variety of Bantam class at Birmingham there were fifteen entries, so that, in point of fact, only £3 is offered for prizes for birds, of which one hundred and sixteen pens were entered at Birmingham, whilst £9 is offered for birds which there mustered only fifty pens, the proportion being roughly six to one in favour of the latter.

I mention Birmingham because I happen to have the prize list by me; but I am greatly mistaken if the Game Bantam has not been exhibited for some time past at all our leading shows in far greater numbers than Gold or Silver Sebrights, or Black or White birds.—P.

### DISTINCT VARIETIES OF PIGEONS.

I WAITED to see if some abler hand than myself would raise a voice in opposition (friendly, of course!) to Mr. Brent's pronounced opinion that all the various and distinctly characterised sorts of Pigeons are descended from the common Blue Rock. One would have thought that the personal experience of a breeder would have compelled a man to abandon such a theory, even if he began with a strong bias in its favour.

In the first place, who can we suppose took the trouble to single out those "sporting" birds and convert their peculiarities into distinct and established breeds? That there are certain breeds which pass among us, in these days, as distinct varieties, which are not truly so, every breeder of Pigeons and poultry knows full well, and every amateur beginner discovers to his cost, when he finds that in order to keep his stock from throwing back, he is compelled to resort to certain quasi-dishonest crosses. And this goes far, I think, to disprove the Blue Rock theory, for if it could ever be done it could still be done, the "sports" would still exist; and did any one ever see a Blue Rock with such peculiarities that by all the care and breeding in the world he could possibly convert its progeny into a White Fantail, Carrier, or any other sort? I consider it would be very much the same thing to say that all the "Finches," Goldfinch, "Bully," and all, are derived from one member of the tribe of plain and sombre garb. But then who singled out and kept distinct

the original "sports?" Ah! who? Why I believe that the same Almighty hand that created these beautiful little songsters, created our beautiful varieties of Pigeons in the forms in which we have them, except such as we know to be spurious crosses.

We know there are many (but a minority), who hold Mr. Brent's theory; but, then, they also think that the huge bloodhound and the Blenheim spaniel are from a common stock. Indeed, I am as little disposed to believe all this, as I am to believe that we are only "improved" monkeys, and that we have rubbed off our tails by sitting on them till nature declines to take the trouble to grow them.—W. H. B.

#### AN EGG WITHIN AN EGG.

I was induced to address you a few months ago about a black hen which had become white, your remark being that such changes were by no means unfrequent among Spanish fowls. My bird, however, is not of Spanish blood, but of a mongrel class, of which I would there were fewer.

I am now anxious to make known another curious fact which has occurred in another farmer's poultry-yard. A Goose has just laid an egg of the remarkable dimensions of 10½ inches in circumference and 5 inches in length. The egg was kindly brought to me, and I found the outer shell (which had been broken with a view to domestic purposes) contained within it another hard-shelled egg, each egg having a perfect yolk. Together they must have weighed above 1 lb., as I found that the inner one weighed rather more than 8 ozs. The doer of this strange deed is a venerable bird of seventeen years, is a regular layer, and, I may mention as an amiable trait in her domestic life that, after five of her eggs had on one occasion been hatched under a hen, she readily adopted the young brood, and brought them up.—R. O., *Eglingham*.

#### COMMENCING BEE-KEEPING—MAKING ARTIFICIAL SWARMS.

I AM about commencing bee-keeping, and I do so more particularly with the intention of introducing the humane and depriving system among my neighbours. This is a bee country, but, save a solitary glass filled in the gardens of the gentry, the sulphur-pit is the order of the day. I have a Woodbury straw frame-hive, which I hope to experimentalise with, as much to show my neighbours what may and can be done as with any object advantageous to myself. Being practically ignorant I must seek for advice, and I write for information on two points—first, in making artificial swarms with the frame-hive how far must you remove the old hive with the brood in (who are to rear a queen) from its original place? and if only a few yards, will not all the bees forsake the frame hive and return to the queen and the all-but-empty hive? Is any particular management required?

The next point is this—in order to introduce the humane system I mean to drive the bees from the stalls that are to be taken far and near all round my neighbourhood, take them home, unite them or not as may be required, feed them, and for half the expense see if I cannot obtain good swarms for the ensuing spring. As this plan became known the owners would look twice before they gave their bees away, and I should find that it would be adopted by all as a matter to their own advantage; and thus I should attain the object I had in view, the abolition of the brimstone-pit.—M. D.

[In making artificial swarms it is certainly well to remove the old hive to as great a distance as may be convenient, in order to guard against its being deserted too completely. This evil may, however, be in some measure obviated by confining the bees\* for four-and-twenty hours after their removal, during which period their excitement will abate, royal cells will be started, and the permanent population will be increased by the hatching of perhaps some hundreds of young bees. When forming stocks with condemned bees in autumn it is necessary to unite several in order to insure a sufficient population to build combs freely. The experiment is unquestionably very interesting, but we have found in practice that, setting aside the risk of failure, stocks

\* Ample ventilation must of course be afforded them during their imprisonment.

formed in this way cost just as much as purchased swarms. The best mode of utilising condemned bees in autumn is to employ them in strengthening other stocks which are intended to stand the winter. We shall be glad to be informed of the result of your operations.]

#### BEEES NOT WORKING IN GLASSES—RAISING A SUPER.

CAN you tell me why my bees will not work in glasses? These are of all shapes, and generally quite wet inside.

I have a good stock, with a straw super full of comb. Should I allow the bees to fill the super with honey first, or place a box between the stock and super at once? Is it of any use giving them extra room when once they cluster outside the mouth of the hive? or must I either drive them or let them swarm?—DUMPLING.

[It is not always easy to induce bees to work in glasses, but this reluctance may generally be overcome by furnishing them beforehand with some clean worker-comb. Moisture from the heated air of the hive is always liable to condense in the interior of glasses used as supers. If your straw super be of full size, it may not be advisable to raise it on a box; at any rate you should let the bees take possession of it, and pretty well fill it with honey before doing so. Mere clustering at the mouth of the hive is by no means decisive as to the fact of its being too late to afford bees additional room.]

#### BEE-BROOD DYING.

THE piece of honeycomb which I left at your office is a fair specimen of the condition of a hive which I lately found to contain no live bees. It was very strong in the autumn, and even on March 16th, when I found the bees dead, there were perhaps 3 lbs. or 4 lbs. of honey left, but very dark in colour. Some of the bees were not dead, but in a kind of stupor, from which they did not recover. A great number lay on the floor-board quite dead, and they, as well as the whole of the hive, were of a very dark colour. From the above data can you inform me the cause of death, whether disease, or only a common case of failure? I am not quite sure, but believe the bees had occupied the same hive for at least three years.—SMITH.

[The comb which accompanied your letter contained brood in various stages, but all in an advanced state of decomposition, and in appearance very much resembling foul brood, to which indeed we were at first disposed to refer it. On a more minute examination, however, we discovered some points of difference, which induce us to believe that the brood died of cold some months ago, and that the bees have since been unable to remove it. With regard to the mortality among the bees themselves, it would appear to have resulted from the effects of the late severe and protracted winter. That the queen remained healthy and vigorous almost to the last may be inferred from the fact that we found eggs in nearly all the apparently empty cells.]

#### STRAIGHTENING COMBS IN WOODBURY FRAME-HIVE.

IN your Journal of October 11th, 1864, I mentioned that the combs in my Woodbury frame-hive had got out of the perpendicular, and I was directed to set them straight any warm day in April or May, and set them fast by clips of tin, &c. Now, how am I put them straight? I fear that if I have to pare them away much I shall destroy a lot of brood, and I do not know the best way of making them fast with these clips when straightened. I have just written to order another frame-box, and as soon as I have your answer I purpose trying the experiment and shifting each frame, as I do it, into the new box. I suppose I cannot do better as a first step, than follow the directions given in the Number for March 7th, headed "Bee-driving in Frame-hives."

Can I in any way convert a bar-hive, already filled, into a frame-hive without weakening or injuring the present stock?—A. W. B.

[Crooked combs should not be pared but straightened,

just as you would straighten a bent wire, and kept straight by such temporary appliances as your ingenuity may suggest. It will be best to get rid of the bees entirely by driving them in the ordinary way into an empty box, which must take the place of the hive. Convey the latter into a room with a fire (the kitchen, we should say), shut the doors and windows, and having previously cleared the table operate thereon at your leisure. If any combs be attached to more than one frame they must be partially or even sometimes wholly detached, set flat, and then secured in their proper places by means of wire, strips of wood, and zinc clips in the manner recommended in page 18 of the fifth edition of "Bee-keeping for the Many" (wherein, however, the printer has inverted the woodcut to our everlasting confusion). When the job is completed to your satisfaction, return the hive to its place in the apiary, remove the crown-board, and knock the cluster of bees out of their temporary domicile on to the top of the exposed bars. They will "skedaddle" down between the combs with the utmost alacrity, and the crown-board may then be replaced. The whole, or nearly the whole, of the temporary supports may be removed at the expiration of twenty-four hours, but if any combs are not then firmly fixed, such as are required should remain a day longer.

You may readily convert a bar-hive into a frame-hive by enlarging it from front to back as much as is necessary, but the bees and combs must be shifted into another domicile whilst the alteration is in progress.]

### A QUEEN ENCASEMENT AND DESERTION OF HIVES.

THE pages of my bee journal have been opened but seldom during the discouraging season which we have so long been passing through, and upon those occasions only for the purpose of entering some uninteresting or commonplace observation, or to note some necessary operation; but to have at last a notable stir in our apiary, although it may have involved the loss of a hive, is rather welcome than otherwise, as an indication that we may now, backward though we certainly are, look forward to some few observations worthy of notice and of a place in the above-mentioned journal.

Although the instance of queen encasement which has just come under my observation is but one of many I have witnessed, yet the attention of apiarians having lately been called to this subject, I am induced to narrate one more such instance, although it may not, in its general features, vary much from some others, and, perhaps, will not offer anything new to those who may have turned their attention to this phenomenon.

The 30th of March, although ushered in with a rather sharp frost, with the long-continued easterly and northerly winds still exercising a retarding influence upon our backward and too quiet apiary, yielded in the afternoon of that day to a more genial sun, affording me some little opportunity of judging of the prosperity and strength of my hives, and certainly I felt a little cheered at the increased animation exhibited pretty generally throughout the apiary. One stock, more especially, of bees driven from a cottager's doomed hive in September last, indicated more vigour than I could have expected, knowing well that the tenants were but few, and having ascertained beyond doubt that no robbing or being robbed was the cause of this activity. This stir, though I knew it not, was a premonitory symptom of a general exodus of the whole tenants of the hive, showing how frequently a close observer may be misled in the external indications of a colony of bees. I did not witness it, having left the spot at the time they must have issued, neither had I any cause to suspect their having taken such a step until quite late in the day, when, in casually passing a hive, I was startled at observing a dense cluster of bees at the entrance. Of course I well understood what it indicated—namely, the encasement of a queen; surely it could not be their own sovereign, whom I knew to be a fine fertile one, young bees playing out in some numbers that very day. Still, with some misgivings, I at once commenced an inspection of the hive, an eight-bar box; first, one middle comb was raised, brood in all stages, and bees far more

numerous than I expected to find them, but no queen; another comb, ditto; a third, one side carefully inspected, no queen; but turning it, there she was—a beauty—pacing over the comb, all right, to my great satisfaction. So this imprisoned queen which, of course, I rescued previous to an inspection of the hive was some poor unfortunate wanderer. It did not strike me that I should look for the queenless hive amongst the quietest, rather did I expect an indication of that unfortunate condition in the most restless, at least, after the lapse of some little time; but no, all continued to drop in quietly, except one, and that one the very hive I alluded to as manifesting more than usual activity, so I at once turned it up, a straw hive, and beheld not a bee. Here, then, we have a case of the desertion of a clean, healthy hive, well stored with honey, a fertile queen, as eggs and advanced larvæ indicated, a case also of fraternising with an adjoining hive, and also of violent antipathy towards, and encasement of, the poor queen. I should like to have the opinion of those who may have experienced a similar combination of events, for it is not clear to me why the bees should have deserted their hive.

I have another instance of desertion to narrate, which has turned out highly satisfactory. A late cast from a second swarm of last season, occupying a very old, but clean and wholesome butt, with combs worked down about half way, and a very fair number of bees gathering pollen, and looking promising, deserted on the 31st of March. This hive I had marked as intending to drive and transfer combs and all to one of my tan hives, but the bees have forestalled me, shifting their quarters quietly, singularly enough, to a tan hive, not, however, the one I was preparing for their reception. Although in my garden at the time I was unaware from whence the bees which filled the air proceeded, and I was too anxious in watching the movements of the swarm to ascertain. I soon observed a gradual concentration of their forces towards my large open bee-shed, containing its six hives, three of them tan, two of the latter in a prosperous condition, the other scanty in population and with a somewhat doubtful queen, and which I purpose strengthening in due time with a swarm. Now, I hoped the bees would fraternise with this hive, with or without a sovereign at their head, neither was hope long deferred, for presently I had the pleasure of watching them pouring into this hive, and also saw and captured a very fair queen, which I at once presented at the entrance; a welcome was accorded to the bees, and peace has since reigned, and the old queen, small and insignificant, was ejected three days subsequently.

We had now to look for the deserted hive, and found it to be the one above-mentioned. Why did they desert it, there being brood in all stages and many young bees which we had to transfer to their new hive? So there is no mistake as to this tan meeting with the approval of the bees. I expected the new and old tenants of this hive would all of them shortly return and partake largely of its sweets; but no, not a bee approached it for a day. Knowing, however, that sooner or later, indiscriminate robbery would induce a terrible state of excitement in my garden, I transferred a few lots of the bees upon sweetened paper to the hive, and soon found they possessed the monopoly of its contents, no doubt, to the great improvement of the state of their diminishing larder.—GEORGE FOX, Kingsbridge, Devon.

### OUR LETTER BOX.

BREDA FOWLS (*Anglicus*).—We saw some of these fowls very recently in the Zoological Gardens at Amsterdam. We think there are three varieties—Black, Grey or Cuckoo, and White. They are fine birds, and have many good qualities. They are noticed in "The Poultry-Book for the Many."

IVY ROUND FOWL-HOUSE (*G. N. S.*).—It will not injure the fowls.

STEWARTON HIVES—SIZE OF THE PAVILION IN NUTT'S HIVES (*F. T. Kirkby Lonsdale*).—Mr. W. Eaglesham, Stewarton, Ayrshire, manufactures Stewarton hives. His advertisement, with prices, appeared in our Journal of March 28 and April 4th. Thirteen inches square by nine inches deep is a good size for the central compartment of a Nutt's collateral hive.

ENTICING BEES (*An Old Subscriber, Morpeth*).—The only mode of enticing bees from their home is by placing hives, either wholly or partially filled with comb, in the neighbourhood of an apiary with the view of attracting swarms to enter them. This practice cannot be too strongly reprobated, but can only be guarded against by increased vigilance during the swarming season.

WEEKLY CALENDAR.

Day of M'nth	Day of Week.	APRIL 25—MAY 1, 1865.	Average Temperature near London.			Rain in last 38 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock after Sun.	Day of Year.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 61.6°, and its night temperature 37.3°. The greatest heat was 81° on the 28th, 1840; and the lowest cold, 18°, on the 29th, 1861. The greatest fall of rain was 1.40 inch.

HARD WATER, AND CAN IT BE REMEDIED?

SOMEWHAT singular it is that amongst the many inventions of late years which have for their object the utilisation of substances hitherto accounted useless no one has presented us with a ready, efficacious, and cheap mode of bringing large quantities of hard mineral water into the soft and agreeable condition in which we receive water direct from

the clouds. The increasing wants of the garden, particularly at a time when rain water is least plentiful, render it often a matter of necessity to have recourse to spring water, and as this is not always of a kind agreeable to vegetation, the inventive powers of some of our chemical friends ought to devise a cheap and ready way of making it so, by the addition of some substance that would render it more palatable to the plants to which it is administered. We all know that certain well waters are next to poison to some plants, whilst nearly all are far from grateful; and as so much has been done of late to improve the quality of water intended for domestic use, surely something could be done to improve that artificially supplied to the vegetable world. It appears to be so much easier to prepare a liquid suited to the requirements of plants than one of sufficient purity for the wants of man, that I should like to engage the attention of those gentlemen who have devoted so much time and skill to the town-sewage question to ascertain if they cannot give us something cheap and efficacious to mix with our chalky water, to render it softer and more agreeable to plants, just as the same kind of water is made fit for domestic purposes by the addition of common soda. We all know that water so much charged with lime is all but fatal to a very numerous and important class of plants—Heaths, for instance—at the same time could not that lime be precipitated and the fluid either rendered purer or charged with something more in accordance with the wants of the plants? It is questionable whether even those plants which grow naturally in a chalky soil would not prefer water free from contamination, as there can be no question but that Nature furnishes water in the best possible condition for the requirements of vegetation, and this water we all know is soft, pleasant, and instead of being loaded with earthy or mineral substances, is highly charged with air, and, consequently, less dense than the same liquid is in other circumstances. Now, though it would be difficult to apply water in the same way that rain falls, assuredly water that is often used might be much improved by being deprived of its injurious ingredients, and having others suitable to the wants of plants added.

In calling attention to this subject I would by no means impose any conditions, except that the substances should be cheap, readily used, and adapted to all conditions. Of course some knowledge of the character of the water to be acted upon should exist, but even in this let technicalities be dispensed with as far as possible, and let the ingredients used be of such a nature as not to be injurious to the birds or animals which may partake of the water. It cannot be expected that the same treatment would answer with all kinds of water, but some simple mode of testing the quality of the water might be devised, and that being determined, the proper remedy might be applied. Assuredly this may be accomplished, for, though most likely the first attempts may prove failures, greater difficulties have been overcome.

It is not my purpose here to enter upon the subject of watering plants which have been some time occupants of the natural ground, as that is a matter that may properly be left for another occasion, especially as there is much doubt whether artificial watering under such circumstances is favourable or not. In the case of a large class of plants, however, periodical waterings are the mainstay of their existence, and as these waterings have to be often repeated, the liquid supplied should be to their liking. I need hardly say that potted plants are those most affected by this water question, and I hope our scientific friends will be able to furnish a means by which the use of a liquid both impure and injurious may be obviated; and if they succeed in this they will confer a boon on the gardening world.—J. ROBSON.

CROSS-BREEDING STRAWBERRIES.

IN reply to what is observed at page 287, I suggested President as a good Strawberry to cross La Constante with because of its general excellence as a plant, and also on account of the size of its berries. You could not improve La Constante, except in those two particulars. I imagine that it would be best to cross President with the pollen of La Constante. I would try both ways, because nature is fitful. Eugénie, Wonderful, and especially the Frogmore Late Pines, would, I think, be good sorts to cross with the pollen of La Constante. I would also try the reverse. La Constante is a very good cropper. The land of "P." is just such land as I should suppose it would do well in. The plant in such land receives moisture by capillary attraction, and the crop will last longer than in our warmer lands.

As regards cross-breeding, we can only proceed blindfold, and hope for the best. Not one seedling in a thousand is worth anything.

In the same page I am astonished to see that Eliza (Rivers) is a bad cropper, and shy to run. The converse is the case here. It runs early and abundantly, is an amazing cropper, and in various situations in my garden it always begins and ends the season. I sent Mr Rivers and Mr. Turner 150 runners each, and I am about to send Mr. Turner 100, or more, of the runners. I fancy I have

200 runners to spare. The plantations of Eliza in all ages are most beautiful. About three plants and a half at the first picking will fill a dessert dish. The plantations of this kind were last year picked five and six times clean, being always drenched with water after picking. I supplied the *déjeûner* at Kensington last year with more Strawberries than could be eaten. The sorts were Eliza, Wonderful, and Empress Eugénie. They seemed to give great satisfaction.

I never had a finer array of Strawberry plants than now, nor in more splendid condition. They look like clumps of Firs. The question of "G. S.," at the same page, Mr. de Jonghe must answer for himself. I suppose he meant that when you take up a plant in spring with the soil caked you must slacken it with your hand. If you do not mean to crop it, it is best to shake it out clean. Pot Rose plants, if the soil around them in the pot is clayey, should always be slackened with the hand before they are planted.—W. F. RADCLIFFE, *Tarrant Rushton, Blandford.*

#### A FEW WORDS ABOUT CHISWICK.

"F. R. H. S.," at page 244 of THE JOURNAL OF HORTICULTURE, with great good sense disposes of Mr. Bateman's speech, and writes truly, feelingly, and practically, on the condition of Chiswick and its prospects. I, as a practical horticulturist, feel more concerned about the interests of Chiswick than about the inconsiderate words of Mr. Bateman; and I crave space in your columns to offer my thanks to "F. R. H. S.," and record my esteem for a true "Old Fellow" on the side of gardening.

My introduction to gardening was under Mr. J. D.—, one of the most accomplished gardeners that took a diploma at Chiswick when "The Chiswick of the past was before its day." From my learned master I imbibed a regard for Chiswick, and learned much from its journals or transactions. Chiswick was the object of my first visit to London; although then beginning to totter, there was much to instruct and interest. I saw a slight revival under my lamented friend Mr. G. McEwen, and recently I saw Chiswick in what is styled "a most efficient state." Such effrontery is past belief. I wish here to state that I bring no charge or insinuation against the respectable men who conduct the work at Chiswick. I speak of Chiswick Garden as being one of a public character, which was esteemed in the progress of horticulture, but is now in a state of neglect as regards the objects for which it was founded. It has been stated that some of the chief objects for which Chiswick Garden was founded having been accomplished, it is no longer important to that end. Why, the same loose remarks might be applied to the leading universities in England, Scotland, and Ireland.

Most firmly do I believe that a high school of gardening is now more needed than ever it was. The duties and requirements of a gardener have not only immensely increased, but are of a much higher order, and require more methodical training. I know that Chiswick, to be of any practical good, must be under the direction of practical talent; that the superintendent must be a man of large experience, familiar with the highest interests of gardening, and give his labour with undivided attention to improve and develop the resources of the garden.

The present arrangements at Chiswick are opposed to the progress of horticulture, and if I did not believe, with your correspondent "F. R. H. S.," that Chiswick has yet valuable resources, I would not trouble you with a remark on Chiswick in its present state. Kew would never injure Chiswick if the garden were conducted as a garden of enlightened experiment and progress.

My employer—an "Old Fellow"—goes to Chiswick and complains that the neglected state of the arboretum, and the trees without names, and walks in bad order, make a visit a trial; in the houses he sees certain plants that interest him, but finds they are without names. The Vines, as a collection, are interesting, and in the right place; the hardy fruit trees are another established feature; but what can be said of any special plan or system of culture? In speaking of the fruit trees, I am not unmindful of the services of Mr. R. Thompson. Now, Chiswick, as it should be, would be a great aid as a standard of fruit culture; it

should also be a position for a young gardener to acquire a fellowship, and give a status and finish to young men of character, which rarely or never can be acquired in private gardens.—C. M. D.

#### VISITS TO GARDENS PUBLIC AND PRIVATE.

MR. B. S. WILLIAMS'S, VICTORIA AND PARADISE NURSERIES, HOLLOWAY.

WHEN I last visited Mr. Williams's, the Victoria Nursery was quite in an embryo state, and all the energies of this rapidly rising establishment were concentrated in the Paradise Nursery. Now, however, I saw a great change, and indications of a still greater one. Independently of the houses that have arisen since I was there, others are in progress of erection, and before long nearly the whole of the ground will be covered with glass. The more valuable productions, for whose culture Mr. Williams is so noted, are being removed there, and hereafter the older nursery will be given up to more hardy things, while the general nursery stock will be grown at some distance. London is now so rapidly, like the fabled cuttle-fish, extending its great tentacula on every side, drawing into its capacious maw the green fields and open spaces that men now only in middle life played in when boys—that perforce the nurseryman who desires healthy stock must seek space elsewhere, and even the foot of Highgate Hill is too much in London to attain this.

Two features particularly struck me in looking over Mr. Williams's varied stock—the very fine specimen plants that he possesses, and the rich and varied selection of new, rare, and choice plants. The greater portion of the former are contained in the new show conservatory which he has built at the entrance of the Victoria Nursery, at the bottom of Highgate Hill. This beautiful building, certainly one of the finest in the neighbourhood of London, is 100 feet long by 40 feet wide, with a broad walk up the centre, wide enough for crinoline in its most capacious days—days which all gardeners will rejoice to hear are on the wane. These specimens Mr. Williams has been gathering together from various sources, more especially from the continent. Many of them are arranged in pairs—two fine pairs of *Yucca variegata*, said to be the finest in growth, a pair of *Yucca Stokesii*, *Zamias*, *Cycas revoluta*, *Dracæna indivisa* and *lineata*, *Chamærops excelsa*, *Dracæna draco*, *Rhododendron Nuttallii*, again showing splendidly for bloom, and other plants of a similar showy character and in fine condition; interspersed with these are some magnificent specimens of tree Ferns. *Cyathea dealbata*, *medullaris*, and *excelsa*, *Dicksonia antarctica*, *Cibotium princeps* and *Schiedei*, were amongst the very fine ornamental Ferns that thus adorn this house. The last of these deserves a passing notice. The fluffy down that envelopes the young fronds is one of the most certain styptics that I know, and any one who grows large Ferns would be really conferring a benefit on his neighbours by growing it. It was only the other day that in pruning I sliced off a large piece of my thumb. Having some of this by me I applied it, and although the wound gave great promise of bleeding profusely, it instantly stopped it. The collection of *Yuccas*, and *Dracænas*, and allied plants in this house is alone worth the journey for those who admire such things. Passing out of this house, of which there is the less need to say much, as an excellent description and engraving of it appeared in the last volume of THE JOURNAL OF HORTICULTURE, into the garden, there is a large Fern-house in course of erection, and ground is being prepared for five span-roofs for Orchids, &c. We then come to a greenhouse, in which is a nice stock of Heaths and hard-wooded plants, such as *Aphelaxis*, *Genetyllis*, *Boronia*, *Dracophyllum*, well set for bloom, and in very healthy condition. In a Pine-house was a large collection of young Pines, including a goodly number of what is said to be one of the finest in cultivation, and which I have seen largely grown in France—Charlotte Rothschild. In another house was a large stock of Geraniums, including Beck's new greenhouse *Pelargoniums*, and some *Zonate* of Mr. Williams's own—Annie Williams, in the way of Mrs. Milford, and Golden Nugget. Mr. Williams speaks highly of Variegated Stella as a good addition to the Nosegay section with variegated leaves.

Facing the other entrance to the Nursery are two small houses, in which are some fine specimens of Azaleas, comprising some of the newest and best kinds.

The Paradise Nursery still retains a large number of those valuable plants for which Mr. Williams's establishment is so famous. Thus in his intermediate-house were fine plants of *Zamia Lehmanni*, *Cycas circinalis* in fruit, *Croton picta*, *Cyathea elegans*, *Cyathea Smithii*, and some very fine plants of the very useful *Statice*—*macrophylla*, *Holfordi*, and *profusa*, together with a new one not yet named. Here also were some of those curious half-standard French *Epiphyllums*, which, however, were a failure. They are apparently grafted on a stove stock, and hence they will not do, as they were promised, in a greenhouse. The Orchid-house, as might be expected from Mr. Williams's high repute as one of the first cultivators in the kingdom, was exceedingly rich in kinds, though, save in a few instances, one does not expect to see the fine specimens which are to be seen in such establishments as Mr. Rucker's, Mr. Warner's, or Mr. Day's; while the vigorous health of the plants bore ample testimony to the success which both Mr. Williams and his intelligent foreman, Mr. Burton, have attained in the cultivation of this beautiful and popular tribe of plants, for now that the cool-house treatment has proved to be so successful, it has brought their culture within the reach of a number of persons who never before thought of it. *Bletia* sp., very pretty and sweet; *Cypripedium biflorum*; *Sophranitis grandiflora*, with bright scarlet flowers; *Vanda tricolor* and *suavis*; *Dendrobium Dayanum*, quite new, with purple lip; *Cattleya quadricolor*, figured in the last Number of Sir Wm. Hooker's "Botanical Magazine;" *Phalænopsis Schilleriana*, *amabilis*, and *grandiflora*; *Dendrobium intermedium*, very delicate in its colouring, were amongst those in flower. Besides these, there were *Vanda gigantea* and *Batemani*, *Oncidium sarcodes*, and other new and rare kinds. Some of the healthiest plants of *Anæctochilus* that I have seen were here, and not grown in a case as generally. Fine plants of *setaceus*, *cordatus*, *Lobbii*, and a new one allied to *Roxburghii*, were amongst the most remarkable. The very fine collection of *Sarracenias* which Mr. Williams exhibited at the Royal Horticultural Society's meetings were also to be seen here, and some fine-foliaged plants, such as *Peperomia arifolia*, *Chameranthemum reticulatum*, and others.

Mr. Williams's collection of Ferns is a very rich one; and from the tiniest Fernlet (if we may use such a term) to the gigantic tree Ferns of New Zealand and Australia, they are to be seen here in every condition. The beautiful Gold Fern, *Gymnogramma Laucheana*, has produced some fine seedlings, many of which promise to be very distinct; while the beautiful young fronds of *Lomaria L'Herminieri* show that bright colour is to be had in this beautiful tribe, for they are of a bright rosy pink. *Gleichenia microphylla*, and a new species allied perhaps to *pubescens*; *Alsophila latebrosa*, a very rich orange green; *Platyterium bifforme*; and *Davallia aculeata*, with very graceful foliage, were amongst some of the most remarkable that I noticed.

It were tedious to enumerate the large collection of fine-foliaged and decorative plants that Mr. Williams has congregated here; but a few I would fain notice, such as *Nidularia picta*, a Bromeliaceous plant, with fine foliage, and producing a spike of bright scarlet flowers; *Jacaranda filicifolia*; *Oreopanax dactylifolium*, with its curious, broad, deeply notched leaf; *Tradescantia odoratissima*, with bright blue-tinted flowers; *Maranta striata* and *Van den Heckeii*, and *Pachycentra Walkeri*, a fine basket plant.

It is well known that Mr. Williams is a diligent caterer for the novelty-seeking public in every way. Be it an Orchid or an Arabis, a botanical curiosity or a simple florists' flower, he is glad to avail himself of it to please those Athenian characters, who ever want some new thing. Thus, he has a very curious *Fuchsia*, in which the flowers, instead of being pendant, stand upright, making it not only a remarkable object, but also very desirable for bouquets; a beautiful-striped *Petunia* from Mr. Holland, who is well known as such a successful raiser; and a brilliant-flowered *Calceolaria*, called Bird of Paradise. He has also a very curious Azalea, unlike any of the striped kinds in cultivation, called *Splendidissima*, of which I hope to see more by-and-by. Mr. Williams has also largely imported *Lilium auratum*, and, besides that, four or five varieties of a Lily

which the gentleman who sent it to him from Japan says is far beyond what we have come to regard as the queen of Lilies; if so, the lovers of this beautiful tribe have a rich treat in store for them.

I have endeavoured to give a passing glance at the many treasures contained in Mr. Williams's two establishments, and I know have failed to convey anything like an adequate notion of their value and beauty; but any one who is desirous of seeing with his own eyes is sure to meet a courteous reception, and if he is at all affected with the floral mania in any form or shape, it cannot but be that he will catch the virus in some way or other.—D., Deal.

## ROYAL HORTICULTURAL SOCIETY.

APRIL 18TH.

FLORAL COMMITTEE.—The Committee assembled on this day, and made the following awards. Mr. Turner, Slough, exhibited a very superb collection of Azaleas, one mass of brilliant flowers, which fully occupied one corner of the council-room. For this the Committee awarded a special certificate; and having recommended that one of the Society's medals should be given for the same, the Council readily acceded to the proposal, and awarded to Mr. Turner the silver Banksian medal. Mr. Turner also sent a new *Bougainvillea* with pale pinkish red bracts, forming a pleasing contrast with the mauve-coloured varieties—first-class certificate, and four seedling *Auriculas* selfs. One named Godfrey, a dark mulberry purple, a fine flower, received a first-class certificate; *Auricula Harry*, a lighter shade of the same colour, a second-class certificate. From the same exhibitor came also a Hybrid Perpetual Rose General de Hautpout, and *Cineraria Herbert*, a nice flower with bright blue margin.

Mr. Bull, Chelsea, exhibited a great curiosity in the form of a double *Mimulus*. The varieties *Mimulus duplex* Andersoni and *Mimulus National* were awarded a first-class certificate. The double form of this *Mimulus* resembles the *Polyanthus* known as *Hose-in-hose*, having the appearance of one flower being placed in another, the calyx forming a second flower, and exactly resembling in colour and markings the true flower. When the flower falls the calyx remains for some time, the plant having the advantage of appearing still in full flower. Among the other plants sent by Mr. Bull were *Sedum villosum* (?) variegatum, a useful plant for conservatory decoration—second-class certificate; Azalea President Victor Van den Hecke, a small white flower with bright pink stripes, but too rough in the outline; and *Salvadora persica*, supposed to be the Mustard plant of Scripture; but from the remarks made by the Rev. Mr. Berkeley there seem to be great doubts as to the identity of the plant. *Hibiscus ferox* was too young a plant for its merits to be decided upon; and *Camellia Cocchi* was a pretty white-striped variety, resembling but not equal to many known sorts in cultivation.

Mr. Jackson, Kingston, sent two *Pelargoniums* for early forcing, but of no merit; and W. W. Saunders, Esq., a collection of interesting plants, and some cut spikes of three beautiful Aloes, never seen before by many of those present, who seemed astonished that what are generally supposed to be uninteresting plants could produce such attractive flowers. Mr. Saunders gave some hints on the cultivation of the Aloes. He likewise sent *Amaryllis* sp., one of those discovered and sent home by Dr. Welwitch; *Remusatia vivipara*, an old plant long known in this country, though but rarely seen, remarkable for its one solitary gigantic leaf; this is one of the curious family of Aroids; also *Eulophia* sp., a dark chocolate-flowering Orchid from Brazil, and *Scilla natalensis*, with broad green foliage, and a tall spike of light blue flowers, for which a label of commendation was awarded.

Mr. Wm. Paul sent Hybrid Perpetual Roses Madame Emile Boyau and Princess of Lichtenstein, new light varieties, nearly white. Both of these Roses will be a great acquisition to every collection. Mr. Osborne, Fulham, had *Bletia* sp. from Japan. This pretty purple-flowering plant, with its graceful foliage, supposed to be nearly hardy, was discovered by Mr. Fortune, who speaks most highly in its praise. It received a first-class certificate. Mr. Osborne

sent also a small collection of other Orchids. Mr. George Smith, Hornsey Road, had *Pelargonium Stella Variegatum*. This received a certificate last year. Messrs. Low sent a beautiful collection of Orchids, for which a special certificate was given. Among them were fine plants of *Dendrobium Dalhousianum*, a very handsome Orchid—first-class certificate; *Erica fragrans* from the Cape of Good Hope, with close, erect, bright pink flowers, delicately scented, a very useful variety—first-class certificate; and *Phalenopsis* sp. *pulchella* (?) from Moulmein, a very small but beautifully-marked flower. From W. Marshall, Esq., came a collection of Orchids and other plants, a fine specimen of *Phalenopsis grandiflora*, *Odontoglossum Bluntii*, said to be the *O. Alexandræ*, but not yet proved to be so, a very pretty Orchid—first-class certificate; *Tropæolum*, &c. A special certificate was awarded for the collection. Mr. Parsons sent *Gymnogramma Parsonsii*, a very curious golden and crested Fern—first-class certificate; and G. Cooper, Esq., *Dendrobium nobile*, *Sophranitis grandiflora*, and *Azalea Roi des Doubles*. Messrs. Backhouse, York, exhibited a new *Anemone*, *Stellata fulgens*, most brilliant in colour, but a tender plant—first-class certificate; and Mr. Williams, Holloway, *Pteris* sp., five-lobed fronds, a very pretty Fern—second-class certificate; a fine cut head of flowers of *Rhododendron Nuttallii*, with gigantic creamy white flowers as large as dinner tumblers—special certificate; *Amaryllis refulgens*, a fine bright dark scarlet flower, rather deficient in form—second-class certificate; *Bletia* sp.; *Sophranitis grandiflora*, a fine specimen—special certificate. In Mr. Williams's collection were some beautifully variegated Aloes, and a special certificate was awarded for it.

Mr. J. Veitch sent four varieties of his beautiful new *Primula cortusoides*. These plants, from Japan, are said to be hardy, and will be most useful among other spring flowers: three of them, *P. alba*, nearly white; *P. grandiflora*, pale pink; and *P. amœna*, dark rose, received each a first-class certificate. Seedling *Rhododendron Henryanum*, with only one large white flower, was likewise shown by the same firm. A special certificate was awarded for Mr. Veitch's collection, which contained many beautiful and rare plants. Mr. Ayres, Biggleswade, exhibited two seedling *Zonate Pelargoniums* and four seedling Conifers named *Thujas*, but proved to be *Retinosporas*, two of which—*Lambertiana* and *prona*—received first-class certificates. Messrs. A. Henderson & Co., Pine Apple Place, exhibited a new *Begonia* of a climbing habit, very suitable for baskets; *Eriocarpus reticulatus*, *O. co. anax dactylifolium*, and *Anadenia pulchella*. These plants by some mistake were not entered, and, consequently, not brought before the Floral Committee. Lady Dorothy Nevill exhibited the curious *Nardoo* plant, *Marsilia macropus*. This plant is said to be eaten as a salad by the Australian cannibals.

**FRUIT COMMITTEE.**—A collection of finely-coloured Apples, consisting of upwards of sixty varieties, and all of them in an excellent state of preservation, was shown by Mr. Rivers; but as he expressly stated in a letter accompanying the collection, that they were intended for the scientific meeting, and not for the Committee, they were not adjudicated on. From Lady Dorothy Nevill came fruit of the *Loquat* (*Eriobotrya japonica*); and from Mr. Lee, Clevedon, near Bristol, three dishes of Apples, one of which resembled the *Hollandbury*. *Roundway Magnum Bonum*, which had previously been submitted to the Committee and received a first-class certificate, was again shown by Mr. Turner, of Slough; and Mr. Melville, gardener to the Earl of Roseberry, Dalmeny Park, Edinburgh, sent two kinds of Sprouts, one of them called *Tom Thumb* being very dwarf, but neither of them equal to *Brussels Sprouts*.

At the scientific meeting held on the 18th inst., W. Wilson Saunders, Esq., presided, and the awards of the Floral Committee having been read by the Rev. Joshua Dix, the Rev. M. J. Berkeley proceeded to point out and comment on the most remarkable of the objects exhibited. He first directed attention to the fine collection of Apples sent by Mr. Rivers, who accounted for their high colour and excellent preservation, first, by their having been kept in a cool cellar with a temperature of 44° all the winter, and second, by the season having been dry, and their being produced in an open

exposure. The fruit of the *Eriobotrya japonica* or *Loquat*, from Lady Dorothy Nevill, was then briefly alluded to; also the *Marsilia macropus* or *Nardoo* plant, on the fruit or sporangia of which the expedition of Burke and Wills lived. Spores were allied in their nature to the pollen of *Phænogams*, and Mr. Berkeley mentioned as a curious fact that the pollen of a species of *Typha* was sold for food in the bazaars of the East. *Dendrobium Dalhousianum*, *Odontoglossum Alexandræ*, and a species of *Bletia*, which was of interest from its being likely to prove nearly, if not quite, hardy, and the magnificent spike of *Phalenopsis grandiflora* from the garden of Mr. Marshall, of Enfield, were then pointed out, and with respect to the last Mr. Berkeley mentioned that the stem of the Bornean *Phalenopsis* is always brown, whilst that from the Phillipines is green. In reference to variegated *Yuccas*, it was remarked that if plants grown in heat were removed to a cooler temperature the variegation was more marked in consequence of the chlorophyll being more fully developed in the cold. Mr. Berkeley, in speaking of *Gymnogramma Parsonsii*, stated that spores taken from the normal parts of Ferns usually produced seedlings of the usual character of the plant, whilst those from abnormal parts produced abnormal plants. With reference to the new red *Bougainvillæa*, he believed that it was the result of a cross between *B. speciosa* and *B. glabra*, the bracts of the former being obtuse, whilst those of the latter were cuspidate. A plant of considerable interest was that sent by Mr. Bull as the *Mustard-tree* of Scripture (*Salvadora persica*), and which was the only species in the genus. He had his doubts, however, whether this plant was really the one alluded to in the parable, for the name of one plant was sometimes in the course of time transferred to another, thus the old *Primrose* was our *Daisy*, and the old *Eglantine* was certainly not our *Sweet Briar*. Dr. Royle, however, who was the botanist that had bestowed most attention on the plants of Scripture, considered the one before them to be the true *Mustard* tree. It certainly grew to be a tree 20 feet high on the shores of Lake Tiberias, where the parable was spoken; but Dr. Hooker had informed him (Mr. Berkeley) that when in Palestine he saw *Sinapis nigra* all over the country, that it there grew 10 feet high, and that the *Salvadora*, on the contrary, was a rare plant; and he (Mr. Berkeley) thought that the balance of evidence was in favour of the *Mustard* of Scripture being the same as our own. Mr. Veitch's new *Primulas* and *Rhododendron*, Messrs. Backhouse's *Anemone fulgens*, Mr. Williams's head of *Rhododendron Nuttallii*, a *Euphorbia* from Mr. Wilson Saunders, Mr. Bull's *Mimulus* having the calyx coloured like a second corolla, and other plants were also pointed out to the meeting.

The Chairman then begged to say a few words with regard to the plants which he had himself sent. The *Amaryllis*, he said, had been discovered by Dr. Welwitsch who, like Dr. Livingstone, had started to make observations in the interior of the continent of Africa, but departing from the other side. Welwitsch, however, was seized with illness and could not cross, but singularly enough he and Dr. Livingstone met, and near there this brilliant *Amaryllis* was found. Mr. Saunders said, he had likewise sent some Aloes in bloom, for it was generally thought that these plants were of little interest, but they were not understood. The common mode of cultivation was to starve them out of existence, but this was a great mistake, for under liberal treatment and with a moist atmosphere they produced some of the finest of flowers. He had also sent a leaf of *Emusatia vivipara* remarkable for its great size and short duration. On first starting into growth the leaf is rolled up like a piece of paper; it then begins to expand but is very flabby, it acquires solidity by degrees, but in six weeks from its appearance it dies down and the plant sinks to rest.

Major R. Trevor Clarke, who possesses nearly every kind of Cotton grown in this country, offered some observations on its culture. Discarding the distinctions of annual and biennial, he said that for cultural purposes the Cottons might be divided into two distinct races, that of the eastern and that of the western hemisphere, and each of these races was divisible into two sections, the early and the late-flowering. Of the early-flowering kinds of the South American type (*Gossypium barbādense*), those most likely to come into the hands of amateurs, were the *Sea Island*, the

Egyptian, apparently an inferior race of the same; the New Orleans, to which he referred the magnificent Vine Cotton; and, lastly, that known by the name of nankinense. The seeds of this section should be sown in February, or even so early as January, an important point being to have the plants strong and woody before the work of reproduction began. A light soil was most suitable at first, but as they advanced in growth they required a strong loam, and with sufficient light, heat, and water, in this they would grow very vigorously. If red spider made its appearance a moister atmosphere should be maintained. Ten-inch pots were the size which he recommended, but if only a pod or two were required, a smaller size would do. The conditions requisite for the production of firm wood, short laterals, and well-filled pods, were moderate pot-room and a moist atmosphere during the period of growth. With this treatment the plants flower about midsummer, and continue flowering till late in autumn, when they may either be thrown away or preserved till the following year, when they should be cut down to the firm wood in spring. With regard to the late-flowering sorts, they would, perhaps, show a flower or two in November, and then rest for three months till spring, when growth would recommence. Such kinds should be sown later than the early ones—say in April, grown on during the first year, and fruited in 10-inch pots in the following season. The principal of such kinds were the West Indian green seed, the Mexican Gulf Hill Cotton the Bourbon, the Kidney, and the Peruvian. *Gossypium indicum*, Major Clarke stated, should have more heat, good drainage, and light soil. The small-growing sorts of this family were well worthy of cultivation, being pretty stove plants.

Mr. Dix called attention to a piece of *Aracaria imbricata* which he had found in a wood near Mr. G. F. Wilson's residence, at Weybridge, and which, almost incredible as it might appear, was, he had been informed, barked by hares and rabbits, and many trees had been barked in the same way. The Chairman thought that the mischief was more likely to have been caused by squirrels, and inquired how high the trees had been barked. Mr. Dix said 2 or 3 feet. Mr. Graham stated that he had found train oil, assafetida, and brimstone an effectual preventive of the attacks of hares and rabbits, and the application would last for two years.

Major Clarke begged to direct the attention of the meeting to a small collection of plants which he had sent, as illustrating a horticultural trick, which was based on the fact that seeds will remain dormant for a length of time, when there is no influence to call their vitality into action. When his friends going abroad offered to send him seeds he told them he did not want anything of the kind, but if they would go into the jungle and send him a spadeful of jungle earth that was all he wanted, but the only person who had done so was a brother of his. The soil sent home was put in a moist stove, and in four weeks the pans were alive with vegetation. Major Clarke concluded by presenting the ladies with Hyacinths and Primroses which he had brought from his garden at Daventry.

The proceedings concluded with votes of thanks to Mr. Rivers and the other exhibitors, and to Major Clarke for his observations on Cotton.

### CROWN EAST COURT,

THE SEAT OF A. H. ROYDS, ESQ.,

Is about three miles from Worcester. Having introduced myself to Mr. Cox, the head gardener, with a request to see around the place, he very willingly consented and acted the part of a good cicerone, by directing my attention to everything worthy of notice. The first place entered was the kitchen garden of three acres. It contains a range of vinerias, 120 feet long by 18 feet wide, in three divisions. Among the Grapes grown is the Alicante, which Mr. Cox prefers to Lady Downe's. The Alicante is generally supposed to be a synonyme for the Black Prince; but this Grape appears to be a distinct variety. There is also another range, 60 feet long by 18 feet wide, and likewise in three divisions. The first contained fruiting Pines, the principal sorts were Queens, Moscow Queens, Montserrats, and Providences; the second division was occupied by Cucumbers;

and the third division by succession Pine plants. Three Providence Pines weighed 30 lbs., and there were some good Queens only fifteen months old, in fruit. Another range of pits, 68 feet long by 10 wide, in four divisions, contained Melons, Strawberries, Kidney Beans, &c. In the Fern-pit were fine specimens of *Gymnogrammas*. All the houses and pits were heated by one boiler (Walker's); the fire passes through the tubes, it requires no brickwork to set it in, and it is self-feeding.

All the dwarf, standard, pyramid, and wall-fruit trees have only been planted five years. They were fine healthy trees bearing immense crops. Mr. Cox pursues a system every year with his fruit trees, which, to judge by his crops, is worthy of adoption. In the November of one year he lifts the points of the roots, and the following season he lifts the base of the tree. The collection of Apples included good examples of Cellini, Hawthornden, weighing 18 ozs. each; Warner's King, a lemon-coloured Apple weighing 19½ ozs.; Blenheim Orange, beautifully coloured; indeed, the bright and rich colours of all fruit attest the genial climate and fertile soil of Worcestershire. It may be well to mention, that those styled pyramids are upright trees, from 3 to 6 feet high, and upwards. These are kept pruned to furnish branches all round the stem. Of the collection of Pears, the following were conspicuous for size and quality:—Beurré Diel, which is kept thin of branches to admit sufficient air amongst its large foliage; Easter Beurré; Knight's Monarch, Thompson's, a most delicious first-rate Pear; Ne Plus Meuris, one of the best late Pears, although not so handsome as some; Louise Bonne of Jersey; Glou Moreceau; Bergamotte Esperen, a first-rate late Pear; Van Mons Léon le Clerc, a first-class Pear, ripe about Christmas; Beurré de Rance; Jean de Witte, of the nature of Glou Moreceau, but keeping longer and not quite so rich; Black Pear of Worcester, a very good Pear for stewing, and which becomes red in cooking. This must be a very old Pear, for it is said that Queen Elizabeth in one of her progresses through the country, observed that they were planted in the High Street, Worcester.

A sheltered situation on the slope of the hill was chosen for the house, which has lately been erected. It is a commodious building, commands a view of several lakes, the resort of wild ducks, widgeons, &c., and has flower-beds on grass in front. The pleasure grounds are furnished with young vigorous specimens of *Juniperus excelsa*, about 7 feet high; *Aracaria excelsa*, 8 feet high; *Picea pinsapo*; *Cryptomeria japonica*, 12 feet high; a beautiful specimen of *Libocedrus chilensis* (the Chilean Arbor Vitæ), an exceedingly pretty conical tree, from the Andes of Chili, where it grows from 60 to 80 feet high; Portugal Laurels, 10 feet high and only planted six years; a good variety and large specimen of Pampas Grass; Lime trees; double white Hawthorns; and Turkey Oaks, one of them a magnificent specimen. There is a beautiful little chapel, in the Gothic style, contiguous to the house and embosomed in shrubs. A short distance from the house is high ground commanding extensive prospects around Malvern and along the slopes of its picturesque hills and rich valley, celebrated for its beautiful scenery, over an extent of country twenty miles in length. The prospect includes the woods of Coteridge Court with its magnificent avenue of Lime trees in double columns, and the diversified scenery of Breda Hill; the varying foliage and autumnal tints of the tawny Plane, the pale yellow Maple, the spotted Elms, the lemon-coloured Ash, and the hues of the other forest trees, giving a gorgeousness and splendour to the landscape that no other season can produce.

To this estate of six hundred acres belongs a character of greatness that is not to be measured by the extent of the grounds, but by the variety in the different distances, the contrasts in the different forms of the boundaries, and the beauty and extent of the landscape scenery, which neither ordinary labour could modify, nor the compass of a pleasure ground include.—WILLIAM KEANE.

OBITUARY.—It is with much regret that we have to announce the loss of Mr. Ogle, for nearly twenty-one years head gardener at Eridge Castle, Kent. He attended the Fruit Committee held at Kensington, on the 4th inst., and

on the same night he was no more. He was much esteemed by his brother gardeners and horticulturists generally, and has left a widow to lament his loss. Mr. J. Johnstone, gardener to the Duke of Wellington, at Strathfieldsaye, a position which he had held for many years, has likewise to be added to the list of the departed.

### ON FORM AND COLOUR.

(Continued from page 280.)

BUT, it may be argued, the foliage of the ordinary bedding plants, Geraniums, Verbenas, Calceolarias, Pentstemons, &c., is deficient in marked character, and, indeed, devoid of beauty. Just so: everything has been sacrificed to this almost childish craving for positive colour. Foliage has been regarded simply with respect to colour; the truss must be so and so, the habit such. Surely the rules so empirically insisted on by florists respecting the form, height, and habit of flowers are akin to the barbarous treatment of cutting trees into peacocks. Does it not savour of this when tweezers and plugs are in requisition at our exhibitions to improve the Dahlia, Picotee, or Chrysanthemum? What a consolation it is that the queen of flowers will not submit to be tampered with! But why not employ, for the present at least, other plants for the purpose? As I have said before, a judicious admixture of plants remarkable for their foliage would add a charm to the flower garden at present utterly wanting. The able and enterprising manager of Battersea Park, Mr. Gibson, has shown what can be done by the use of the so-called foliated plants. Although it may not be advisable to have single lines of *Ficus elastica*, oblong beds of *Cannas* and *Wigandias*, or the black *Coleus* with *Cineraria maritima*, we have abundant proof, from the success already attending Mr. G.'s efforts, of what may be accomplished by energy and good sense to make the flower garden a really interesting and delightful retreat.

I shall not presume to dictate to the intelligent readers of this Journal any new system of flower-gardening, but submit simply a few suggestions, to be taken, as previously hinted, for what they are worth. Reverting, then, to our simile of the trumpet, if the resources of the establishment are limited by all means attempt only a solo, but let there be a good accompaniment. Some of the grandest effects are produced in music by a simple unison, but unison does not mean restriction to one note—there are tones of colour. Suppose, however, for example, we take *Cerise Unique* Geranium or *Shrubland Pet* for a circular bed; plant among these, if not too exposed, the common Fern *Filix-mas*, so that the fronds shall partly overshadow the *cerise*, and we have then a varying play of colour from the shadow of the Fern fronds. *Filix-foemina* browns and fades too early in direct sunlight. Or what an exquisite group might thus be formed, or, better still, in the conservatory with *Shrubland Pet*, *Madame Vaucher*, and *Adiantum capillus-Veneris*. Combinations of the various shades of blue and white are beautiful, but should be dashed with crimson to give warmth. Avoid the conjunction of scarlet and yellow, of yellow and blue, and in every case let there be at least one plant remarkable for the beauty of its foliage occupying a central position. It is the key of the picture; on it the eye first rests, and then wanders at leisure over the details. *Cannas*, *Wigandias*, Ferns, large plants of *Centaurea candidissima*, or even the great variegated Thistle, and the Artichoke, make fine centre plants: no doubt your experienced readers could suggest many others equally or more suitable. Crimson, *cerise*, and white, and purple and sulphur yellow, form pleasing combinations; so also crimson and variegated Balm, purple and white. Generally speaking the secondary colours are more manageable and harmonise best.

I will not weary your readers with further detail: no doubt many of them have enjoyed during the past summer more beautiful combinations of colour than I could possibly suggest, or than may even be found in the catalogues of the seedsmen, in which may be discovered not only scarlet and yellow, but *Perilla* and *Feverfew*, the bassoon, and the *piccolo*. I may add, however, that my most successful bed last summer was a pear-shaped one, edged with variegated *Alyssum*, a group of *Imperial* crimson Geranium in the

centre, *Purple King* dashed with *cerise* in the body of the pear, and yellow *Calceolaria* at intervals round the inside edge of variegated *Alyssum*. It was, however, merely a colour bed. A reaction, however, has taken place already. A growing improvement is manifest in the taste for plants with fine foliage, and especially Ferns. It is the function of horticultural societies to foster and promote this taste. How may this be done?

A complaint has long been urged against the great flower shows, that there is little or no novelty in them, and this is especially the case with large miscellaneous plants—the same plants occupy the same places year after year. Why not, in place of one of the long central stages at the Kensington Gardens, allot space for groups of plants, circles, oblongs, or pyramidal form, and, as an extension of the system, offer prizes for the best arrangement of flowers in beds? It would be easy for gardeners to reserve in pots or square pans sufficient plants for the purpose. Let them be arranged by the exhibitor himself, under proper regulations, on a piece of well-kept lawn. After the decision of the judges the prize groups could be readily removed to a more conspicuous position reserved for them within the exhibition tent, or elsewhere. The great horticultural societies would thus enable the public to form for themselves an estimate of what is most suitable for them, a more correct knowledge of colour and form as regards gardening would be disseminated, and the public taste improved. It would add, moreover, an interesting and attractive feature to our metropolitan shows.—T. W., Harrow.

### BULBS UNPLANTED FOR A YEAR—VITALITY OF SOME FLOWER SEEDS.

IN answer to a query in No. 211 (April 11th), I am able to state that, having accidentally mislaid some Tulip and Turban *Kanunculus* bulbs at the time of planting, they were left out of the ground till the following season, when I planted them in the ordinary manner, and that both kinds flowered as well as those which had only been the usual time out of the ground, and, I think, a little earlier. I will also mention that having once collected a large quantity of seed from some peculiarly fine Brompton Stocks I continued sowing portions of it for eight or ten years, and it did not, in the least, deteriorate.

I lately tried an experiment on some *Anemone* seed, sowing the product of three different years in three ridges in the same bed, and I could not perceive any difference, either in the time of their coming up or flowering, between the three-year-old seed and that which had been lately gathered.—AGNES.

### NEW BOOKS.

*Select Orchidaceous Plants.* By Robert Warner and B. S. Williams. Part 10.

We give the highest praise when we say that this is quite equal to any of its predecessors. It has portraits, with the usual amount of history and cultural directions, of *Galeandra Devoniana*, *Epidendrum Skinneri superbum*, *Arpophyllum giganteum*, and *Lælia purpurata*. This completes the volume, comprising a series of forty plates, and is deserving of a place not only in the library of every lover of gardening, but on every drawing-room table. We are very glad to see the announcement at the conclusion of the introduction, that a second series of forty plates, forming a companion volume, is preparing for issue in ten parts.

*The Chrysanthemum, its History and Culture.* By J. Salter, F.R.H.S. Groombridge & Sons.

MR. SALTER, of the Versailles Nursery, Hammersmith, has been known for about thirty years as a special and most successful cultivator of the *Chrysanthemum*. He has now published a volume relative to this his chosen flower. It is well illustrated with portraits of model blooms; it gives an interesting history of the introduction and progress of this florists' flower, and ample directions for its culture and training as standards, as pyramids, as specimens, and for cut

flowers; Pompons as well as the large-flowered varieties are fully considered; and the volume concludes with descriptive lists, arranged not only according to their colours, but alphabetically, and pointing out for what purpose each variety is especially suited.

We strongly recommend the volume to our readers, and we will only quote one or two passages tracing the progress of the flower in this country.

"The first *bonâ fide* English seedlings were raised in Norfolk by Mr. Short and Mr. Freestone nearly thirty years ago. Nonpareil, Norfolk Hero, Prince of Wales, and a few others, were the pioneers. About the same time, 1836, an amateur in Jersey turned his attention to the Chrysanthemum; having no doubt received some plants from his French neighbours, and heard of their success in saving seed, he was induced to attempt it, especially as the Channel Islands had long been celebrated for the production of seedling plants. The result exceeded his most sanguine expectations, for he raised upwards of five hundred seedling Chrysanthemums, which were purchased by Mr. Chandler, of the Vauxhall Nursery. There are many persons who remember the *éclat* attending his annual November exhibitions, especially when the Jersey seedlings became known, for not only were the flowers more beautifully incurved, but many were more double, and showed far greater diversity of colour than those already seen; among them were Adventure, Beauty, Calypso, Celestial, Champion, Chancellor, Countess, Defiance, Eclipse, Elegans, Enchantress, Formosum, Goliath, Hero, Imperial, Invincible, King, Lucidum, Magnet, Marquis, Paragon, Surprise, and Topaz. Several of these still remain as favourites in the conservatory, while Beauty, Formosum, and Lucidum are found in most prize stands of cut blooms.

"In 1838 the author took up his residence at Versailles, near Paris, and finding the climate of that city particularly suited to the cultivation of the Chrysanthemum, he imported from England all the Chinese varieties, besides most of the Norfolk and Jersey seedlings. Shortly afterwards about 250 good French sorts were added, so that in 1840 this collection numbered between 300 and 400 varieties. Upon looking over the list of that year, it does not appear that there were more than thirty with incurved florets or petals, and nearly all of these were obtained since 1830. In 1843 seedlings began to be raised in the Nursery at Versailles, and the first fruits of many succeeding years of labour were in

"1844. Annie Salter, Madame Poggi, and Queen of the Yellows.

"1846. Cyclops, Fleur de Marie, and Nancy de Sermet.

"1847. Queen of England, which is acknowledged by all exhibitors of cut blooms to be, both as regards size and perfection of form, the finest Chrysanthemum extant.

"About twenty years ago the Chrysanthemum took its place among exhibition flowers. The first public show of cut blooms was held at Stoke Newington in 1846; this society is the oldest in England, and its annual exhibitions are still among the most attractive in the metropolis. Of late years many similar societies have been established, and at the present time there are no less than twelve in the immediate vicinity of London, besides many others scattered over the length and breadth of the country."

"In 1846 a new era commenced in the history of the Chrysanthemum, for at that time Mr. Fortune brought from China two small-flowering varieties, known as 'The Chusan Daisy and Chinese Minimum.' These were similar in size to those now called Liliputians, and were probably varieties from the true *C. indicum* of Linnæus, or *Matricaria japonica* of Kœmpfer, a plant of which (as previously noticed) grew in 1764 in the Botanic Garden at Chelsea. These would in all probability have shared the fate of their predecessor had they remained in England, for although Mr. Fortune admired them in Chusan, they were considered too small and insignificant for English taste. The French opinion of them, however, was far different, for immediately upon their introduction in 1847 into the already well-known collection at Versailles, the little Chusan Daisy became a favourite. From these two varieties have sprung all the Pompons now in cultivation. Chinese Minimum was a dark

double flower, and produced but little seed; while the other, with its daisy-like semi-double flowers, seeded freely the first year, and the result surpassed the most sanguine expectations; the seedling flowers being more double than the original, and from their compactness and resemblance to a rosette, received the name of 'pompon,' and were called Pompon Biou, P. Chapeau Rouge, P. La Liliputienne, P. Le Nain Bébé, P. Petit Poucet, and P. Tom Pouce."

## GARDEN PESTS.

THE gardener is, in one respect, the most unfortunate of men, for he has enemies in the earth, on the earth, and under the earth. No wonder, then, that one of his most frequent inquiries is, How am I to get rid of such and such a pest?

Having myself, in addition to the ordinary number of enemies, an extraordinary number in the shape of birds, I was induced this spring to try Mr. Rivers's plan of protecting Plum trees by worsted. I had the more faith in this remedy from having often used it for protecting Gooseberry bushes from sparrows in winter. I cannot, however, say that it has answered my expectations with Plums. The worsted was very carefully wound round the trees, and the meshes were only about a foot square; but while the trees in an angle near the house were left untouched, those further off were almost entirely stripped. Leaf-buds, as well as flower-buds, were eaten, and the trees no doubt were as much injured as though they had been over-pruned.

For another enemy, the aphid, I have tried many things, but find nothing better than the quassia water and soft soap, as recommended both by Mr. Rivers and Mr. Pearson. Neither this mixture, however, nor any other, will supersede the necessity of constant vigilance. In fact daily watchfulness and syringing with water must still remain our sheet anchors.

As to ants, neither the arsenic and treacle recommended by Mr. Pearson, nor the arsenic and sugar, &c., recommended by others, have ever proved of the slightest use. The ants are not attracted by the mixtures, and their eyes probably see distinctly the grains of arsenic, which to us appear as an impalpable powder. I try to diminish their numbers in my orchard-house by disturbing them in their haunts, and continually pouring down boiling water, but they seem to increase as rapidly as the boiling water kills them.—G. S.

## TRITOMA GRANDIS.

By this time there are few who are not acquainted with what one may call the grandeur of *Tritoma uvaria* glaucescens, which as a decorative plant in August and September, and even on to the middle of October, has few or no equals among hardy herbaceous plants. It is equally effective when used either in long-continued lines or as single specimens in mixed borders. Any one who saw the splendid masses of this plant which Mr. Lees had this year at Tynningham in his mixed borders, cannot fail to have been struck with the effect produced.

*Tritoma grandis* is a plant but very little known, but one which cannot fail to be a great favourite when once its merits are found out. It is a stronger grower than *T. uvaria*, but its great merit consists in its commencing to bloom when the other favourite is past. For several years past we have had it here in great beauty till the end of December. Last year I cut basketfuls of it for decorative purposes the day before Christmas, and this year it is equally fine and late. In colour it is much the same as *T. uvaria*, but throws its immense spikes up to the height of nearly 6 feet sometimes, and not unfrequently it throws out smaller lateral spikes from the main stem.

With *Tritoma grandis* and *uvaria*, this beautiful genus may be had in full beauty for at least five months.

There have been great complaints about *Tritoma uvaria* being diseased, or having become degenerated in England. I have observed no signs of anything of the sort in Scotland; and my opinion is that in many cases the plants are starved in poor hungry soils, and that such is as much the cause of degeneracy as anything else. They like liberal culture, and

delight in deeply wrought soil, with plenty of leaf mould or well rotted dung, and a rather moist soil is better for them than one dry and gravelly.

Clumps of Pampas Grass, edged with *Tritoma grandis*, would be very striking in suitable positions. The flowers of the one would show off the other with great effect, and they both flower at the same season, and delight in very much the same sort of soil. The outline of such a clump would be

devoid of that which may be termed dumpiness, and on that account would not be so likely to offend the eye of those who have set their hearts against all formally filled clumps in any position whatever. However, I am sure *Tritoma grandis* will give satisfaction to all who are required to cut flowers by the basketful after the middle of October, and will well repay any extra attention devoted to it.—D. THOMSON.—(*Scottish Gardener*.)

### THE MODERN PEACH-PRUNER. No. 8.

HAEDLY any matter is of such importance in Peach-pruning as a right knowledge of the distinctive characters of the shoots. That they differ widely is certain, therefore any instruction on this point must be founded on some common principles before it can be of real value. Even the practised pruner is instinctively guided by certain well established rules in his selection or rejection of the coming season's wood, but these rules are the result of longer experience than usually happens to the amateur. The almost entire absence of any classification of Peach shoots in the works of the older writers was an essential defect, and rendered much of their excellent teaching practically useless. Possibly this was owing, in a great measure, to the paucity of illustrations common in those days, for without such invaluable aids it seems simply impossible even now to attempt any profitable instruction.

Modern practice, indeed, by a species of reaction, has rather erred on the side of copious illustration joined to minute detail; but the result has been good, the amateur has largely profited thereby, and this alone would have amply justified the new method.

There is, then, no classification of Peach shoots of any value till we take up Professor Dubreuil's late work on the general subject of fruit culture. Taking, then, this high authority for our basis, we can the more readily approach this interesting portion of our subject.

Under M. Dubreuil's system all shoots are divided into six distinct classes. After careful consideration this number has been extended to eight, and the whole has been rearranged in two divisions. The first four classes are mainly found in long pruning, while the remaining four, though occurring also in that system, are principally to be found in close-pruning, and especially in all orchard-house work. This division is also convenient for reference. Every type of shoot which occurs in ordinary cases will be found ranged under one or other division. To show the unaccountable neglect into which this matter had fallen, it will be enough to mention that new names have been given to several of the classes, which, though well known to pruners, had no recognised nomenclature. These names have been added under the sanction of the best authority, while the shoots themselves have been carefully drawn from nature by practised hands. They possess the additional value of being

now engraved for the first time of the natural dimensions, by which means they can be much more readily distinguished.

#### 1ST DIVISION OF PEACH SHOOTS.

I. THE WOOD SHOOT.—*Fig. 1*, is the wood shoot of the purest type; *rameau à bois*, of Dubreuil. This is a vigorous class, and indicates either a very early stage of development, or, if found in the case of older trees, rather a superfluous amount of sap. It is depicted with the leaf-buds just elongating under the influence of the continuous movement of the ascending sap, exercising an almost mechanical pressure at their axils. Under the powerful influences of light and heat, in a short time each of these buds will become a green shoot provided with leaves, which, elaborating the sap, will speedily augment the dimensions of the whole, both in length and in breadth. This class of shoots is common on young and growing trees. When it occurs as an extension, it is far better to endeavour, by judicious summer-stopping of the buds A, A, A, as they lengthen into shoots, to make them fruit-bearing, and then little or no shortening-in of the extension will be needed at the winter pruning. The tree will thus gain much. A contrary practice will end in producing other wood shoots of No. 1 class, arising from the buds A, A, A. Whenever this unfortunate circumstance occurs, then these wood shoots should be cut very short back to try for fruit again. Of course, it is not supposed that this class of shoot should be laid-in for bearing purposes at the winter pruning. It is naturally a long shoot, and has

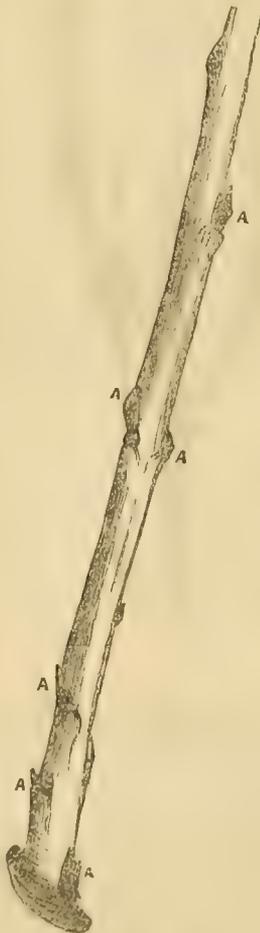

Fig. 1.

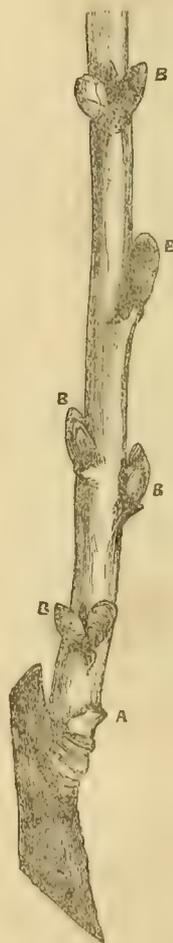

Fig. 2.

occasionally some feeble blossom-buds near its extremity, which are valueless. At the lowest A (at the junction of the one and two-year-old wood), we perceive a wood-bud, which will probably become a short, fruit-bearing spur.

2. THE FRUIT SHOOT. *Rameau à fruit proprement dit*, Dubreuil.—*Fig. 2*, is a type of the ordinary fruit-bearing shoot. This shoot is a good specimen of the long-pruning style. The blossom-buds at B, B, B, are all double, and have a leaf-bud between them. Sometimes they occur as a single blossom-bud and a single leaf-bud. This formation is easy to manage and is variously treated. Sometimes the shoot is laid-in at full length, a reprehensible practice except in the case of exhausted trees where leaves principally are wanted, and sometimes, being cut back to about 10 inches, it is partially disbudded, which seems a waste of material. This class, however, will bear much ill-treatment, chiefly

because it can hardly be cut-in wrongly, as there is a leaf-bud present with each group of blossom-buds.

3. **THE MIXED SHOOT** (fig. 3), *Rameau mixte*, Dubreuil. —This class partakes of the characters of Nos. 1 and 2, having the leaf-buds of the former (only frequently doubled), for some way up, and then changing into the fruit-bearing groups peculiar to No. 2. It indicates a stronger growth than class No. 2, and is probably due to a vertical position at the upper side of some branch, or an extension of some bush tree. Perhaps a cold wet spring, abruptly succeeded by bright sun has altered its character and caused blossom-buds to be produced high up the shoot. These changes are, however, subject to laws not yet well explained. This class requires careful summer handling, and is more difficult to prune than No. 2. At the winter season if it present the appearance here shown, it would be well to cut it in very short, and thus divide it. To cut it long so as to bear is, indeed, long pruning, and cannot be recommended here. As an extension it is, however, excellent.

4. **THE GROSS SHOOT** (fig. 4), *Gourmand*, Dubreuil.—This is a dangerous class, and it should never be permitted to appear except as an extension. It is represented of the ordinary thickness, but frequently becomes very much stronger. From it are developed laterals of summer growth, which are called "*anticipés*" (literally premature shoots), by the French. These summer laterals are the bugbear of very close pruners, for on their careful management or otherwise depends the character of their work. We notice that the leaf-buds A are generally not so prominent as in

class 1; and on the laterals, in the case of that on the right, the leaf-buds are double and well placed at the insertion of the lateral on the parent shoot, and therefore no blank space will appear when these laterals are transformed into fruit-bearers. In the case of the left-hand lateral, however, these two leaf-buds are suspiciously distant, and the dormant bud visible at the base cannot be depended on, and if not developed during the ensuing season probably never will be. This is a peculiarity of the Peach, therefore the right-hand lateral is of much greater value than the left-hand one. At BB we notice feeble blossom-buds, with a terminal bud, c. These laterals vary considerably in size, of course. In mid-France they become independent shoots and able to bear, owing to the growth made under those favourable conditions. No. 4 should be checked whenever not needed. It is known by its erect character, darker colour, and well-developed leaves, and should be stopped to about 2 inches when it has made about 6 inches of growth. It will then divide into two weaker shoots of some class or other, generally of No. 1, and become manageable. The *anticipés*, or premature shoots, require a chapter to themselves, and will be further discussed when we come to close-pruning.

These four classes have much in common, as No. 1 easily passes into No. 4 according to circumstances. No. 2 is the highest organisation of course, and No. 3 a class only of a mixed character. More need not be said at present on this head, as these shoots will have to be referred to continually.—T. C. BRÉHAUT, *Richmond House, Guernsey.*

Fig. 4.

WORK FOR THE WEEK.

KITCHEN GARDEN.

The present dry weather is particularly favourable for the destruction of weeds, and it should be remembered that the destroying of one weed now is destroying what would shortly be the parent of many. The same may be said of insects. Beans, earth-up the early crops, and where they were put in the ground in the end of last year they should be dug between with a fork. Make another sowing. Cauliflowers, raise the hand-glasses and loosen the soil between the plants, and afterwards give them a good soaking with manure water. Cucumbers, the young plants intended for the ridges to be stopped and repotted if they require it. Sprinkle the plants in the frames early in the afternoon, and shut up. Water liberally round the sides of the frame when the heat of the day dries the soil. Lettuces, water the early ones if necessary, and plant out some of the plants raised in the frames. Melons, the plants very often show one or two fruit at an early period of their growth, these should be picked off, as they would prevent the swelling off of others. The vines should first nearly fill the frames, and then several fruit should be impregnated at one time. Give air and water according to the state of the weather and the heat of the bed. Peas, make another sowing of two

or three different kinds, according to the consumption Potatoes, hoe between the early crops as soon as they are above ground. Where circumstances have prevented the planting of the main crops, it should be done at the earliest opportunity. Scarlet Runners, the first crop may now be sown in boxes, which may be placed in any of the forcing-houses. Turnips, where there are any growing in frames they will require watering in dry weather, which will prevent them from becoming hot and hard. Spinach, make another sowing, attend to the thinning of the early crops. Continue to trench into the soil all refuse vegetable matter, as advised in former calendars, a practice which cannot be too much insisted on. It is better to do so at once than to lay it in heaps in the rubbish-ground, where it not only loses its most fertilising properties, but poisons the air by the gases evolved in decomposition: whereas if trenched into the ground at once, and more particularly if accompanied by a portion of charred material, the greater portion of the ammonia will be retained in the soil, till again taken up in combination with water by the roots of the plants.

FRUIT GARDEN.

See that plantations of Strawberries are free from weeds. Those plants that have been forced may now be planted in

ground thoroughly prepared by trenching and manuring—say in rows 2 feet apart and 1 foot asunder in the rows, and watered occasionally should the weather prove dry. By attention to this early and strong runners may be obtained, which will form strong and well-matured plants in early autumn, leaving them ample time for rest before the forcing season commences. Examine frequently grafts, removing on every occasion the wild shoots. Search for and destroy caterpillars which frequently commit serious injury to the young shoots. Continue moderately the disbudding of Peaches, Nectarines, and Apricots. When Vines have pushed sufficiently to distinguish the fruit-bearing shoots, let all superfluous ones be immediately removed. The blossom of Peaches and Nectarines is so thick that I should suggest the propriety of removing a portion, but perhaps it may be said, Let us wait and see what frost will do, as it seems very much inclined to postpone its departure.

#### FLOWER GARDEN.

The flower-beds should be dug and fully prepared for the reception of the usual summer plants some time previous to planting. Finish, if not already done, the pruning of those summer Roses which were left unpruned for the purpose of retarding their bloom. Insects, especially the green fly and Rose caterpillar, will now be making their appearance amongst the Roses. Pay due attention to Ten-week Stocks, Asters, and Marigolds. If not already done, hardy annuals should be sown after the first shower, and do not forget plenty of Mignonette, the fragrance of which will always render it a favourite.

#### GREENHOUSE AND CONSERVATORY.

See that climbers and all plants of rambling habit have due attention in regard to stopping, water, &c. Camellias forced into wood should have a trifling check as soon as the young leaves have attained their full size. This is best accomplished by diminishing the supply of water at the root. Continue, however, to shade and syringe morning and evening. Pelargoniums and Calceolarias must be kept moist and free from the green fly. A few cuttings of the first may be put in for autumn flowering. Syringe occasionally Camellias, Rhododendrons, and Indian Azaleas after flowering, and shade from the effects of bright sunshine. Continue to pot off Dahlias.

#### STOVE.

See that growing Orchids have due attention as regards shading and atmospheric moisture. Recently imported Orchids require very cautious treatment. Water is out of the question here, they will rot directly. A moderate temperature should be used; 60° will suffice at first, and coming out of darkness they should have a very moderate amount of light. Attend to training the shoots of stove twiners as they advance, and do not allow them to become entangled before giving them attention; also attend to the training and stopping of other plants, and afford free-growing subjects plenty of pot room. Achimenes and Gloxinias, filling their pots with roots, will enjoy an occasional watering with weak manure-water. Repot and propagate Begonias. Persevere in keeping down insects which, if allowed, will now progress with great rapidity.

#### PITS AND FRAMES.

All that can safely be done in the way of hardening off stock preparatory to its being planted out is to give as much air as circumstances will admit without injuring the plants, and to place Calceolarias and the strongest Verbenas in turf pits, where they can be securely protected at night and sheltered from drying winds; and such things, when removed to cold pits should be planted in light soil, which will save trouble in watering, and be much better for the plants than keeping them confined in small pots. Tender annuals that have been raised in heat should be pricked out in light soil, under glass, in order to have them strong before planting-out time.—W. KEANE.

### DOINGS OF THE LAST WEEK.

#### KITCHEN GARDEN.

Cut lots of Asparagus, the warm rains having brought it up fast and tender. What was planted lately is also coming on well. Threw some ashes and charred refuse over all the

young plants, as a reminder to slugs that they are not wanted. As yet they have not shown themselves much this season. The long winter has either killed many or made them burrow deeper; but if the latter, we may expect the warmth to bring them to the surface, to afford some exercise for watchfulness. The best method for keeping them away is constant surface stirring. The best baits for enticing lots of them to congregate are greased cabbage leaves and a small handful of brewer's grains; but to catch them when thus luxuriating you must go to the leaves and grains with a lantern when other people are in bed. Some of the best kitchen-garden cropping we ever saw was at Bicton; but, then, who ever caught Mr. Barnes asleep? We have heard a tale of one of his young men, who was resolved to have the honour of awakening the veteran, actually sitting up until the short hour had struck, and then on calling him being discomfited with the reply, "I have just got my coat to put on." Few men possess such an iron constitution, and even he may be unequal to such wear and tear now. Gardens, however, will soon tell a tale if managed entirely by six-o'clock men.

Watered Cauliflowers under hand-lights with manure water. Cut pretty well the last of those that were grown in largish pots in winter; but now Broccoli is coming in freely, and, therefore, we can do very well till the first under glasses come in. Planted-out more, and pricked out those spring-sown. From this time until the middle of July we generally sow a pinch of seed every fortnight, as we find it best to plant often and but few at a time, in order to secure a constant supply of fine young heads. The larger spring planting affords plenty for pickling, &c. To avoid placing Kidney Beans in vineries, &c., cleared a part of a pit, where there is a hot-water pipe, and top-dressed the pots with old Mushroom-dung, and then plunged the pots in a bed of leaves, so as to lessen watering. The roots may run in the leaves as they like. Sowed also a lot in four-inch pots, part of which, when the plants are stubby and the points picked out, will be planted in earth in a similar pot, and put in an earth-pit with protection in severe weather. Sowed, also, a border for the first crop out of doors. Cleared most of the Radishes from the Carrot-frame to give air and light to the latter. Pricked-off Celery into boxes and pots; did the same with Chilis, Capsicums, &c. Banked-up Cucumber-frames. Hardened-off Potatoes in frames that we may shortly use the glass for other purposes. Planted some more Rhubarb, and divided that which had been forced in the Mushroom-house. If Rhubarb seed is now sown in well-stirred rich soil it will make strong roots by the autumn. Plenty of Rhubarb, Sea-kale, and Asparagus in winter, with some blanched Swedish Turnip-tops, enable the gardener to give a variety. Earthed down the last piece of a Mushroom-bed, which we will have in the house this season. For this bed we used seeds 1½ inch thick, the grass side downwards, and a little loam in the interstices and scattered over all. We have done so often before, and though the produce was good, we did not think the crops were finer than from soiling over in the usual way. Our last summer's bed under the thatched shed, open on one side, is even now doing well. It was mostly uncovered in winter, and we were wheeling the remains out for flower-beds, but we thought the spawn was sufficiently fresh to do more work. A part, therefore, was cleared on the surface, watered with manure water at about 75°, and covered over with dry hay and a little litter, and now it is white with Mushrooms. The bulk of that bed was made with stubble and litter, with a casing of droppings on the surface. It is of no use, therefore, being so excessively particular about materials. We like droppings from the horse and a portion of litter best.

#### FRUIT GARDEN.

Proceeded with tying and nailing out of doors. The warm rains have given a start to Strawberries, which are beginning to show. Those in pots are now doing well, and swelling and ripening freely. When much is done in that way, a Strawberry-house should be provided for them. In vineries &c., where the roof is nearly covered with foliage, the Strawberry plants will swell their fruit, when set elsewhere, but they will neither have the colour nor the flavour of those exposed to the full action of the sun. We are often non-plussed what to do with them, so as to keep up a good succession at this season, the houses where there is heat getting too shaded and crowded for them, and shelves at

the back of pits, where Cucumbers, Melons, and Beans are growing being rather too damp, even with a little air on all night.

We notice what is said of *Blind Strawberries*, at page 304, and so far endorse "W. Y.'s" remarks. It is much the safest plan to take runners from plants that have bloomed. In early forcing many plants come blind owing to the bud being starved by excessive dryness, or rotted by an excess of moisture. In all such cases the plants will bloom well enough if planted out, and often give a crop in the autumn. Those that never had a flower-bud, but show strong-pointed, sharp-angled shoots, had better be thrown away. Sometimes, however, on marking such plants we have found them become fruitful the following season. It is best, however, as we have several times remarked, to choose runners from fruitful plants. Plants that are barren are generally much stronger-growing than the fruitful ones, and produce stronger and earlier runners, and unless precautions are taken these will be apt to be taken off or layered by an inexperienced workman.

One other fact we may mention. Owing to the dryness last summer, our plants of *British Queen* were very small, so much so, that we put three plants into a seven-inch pot, firming them at equal distances round the side of the pot. Several persons noticed these plants in winter and spring, they were so weak, and we were not very hopeful of them ourselves. They are, however, doing remarkably well, throwing up large broad trusses of bloom and fruit, and the foliage is so strong that we have bent it a little over the pot to give more room to the flower-trusses. Such small plants, if the buds are well ripened, often do wonders, and bear larger plants if not equally well ripened.

Planted-out *Melons* in a frame and pit, the latter heated by hot water. In both cases the space appropriated to soil is about 24 inches wide, and the same in depth. We find this quite sufficient for a bed 5 or 6 feet in width. We have several complaints of scorching and injury from steam owing to the shallowness of the frames. Our frames are shallow, from 9 to 11 inches deep in front, and from 14 to 18 inches deep at back. To save labour, as soon as the hotbed settles and the heat rises, and the top material is sweet, we take the above-sized trench out of the centre and lay the soil back and front, placing some old slabs, if we can obtain them, on each side of the trench. The soil is then put in, the frame set on, the soil being entirely below the level of the frame, a little earth is put over the two sides, and some is firmly placed all round the box. The soil in the middle is soon warmed, the less thickness of dung in the centre prevents over-heating at the roots, and as the frame requires no moving or elevating afterwards, there is no risk of unhealthy steam getting in from the livings.

Disbudded shoots in orchard-house. *Cherries* in pots are now a fine sight with bloom, and *Plums* also; the latter are beginning to set. Gave a soaking to that part of the border not previously watered. Use manure water freely now for border and trees in pots, but considerably diluted, so as not to be too strong. Thinned out shoots, and tied in the *Peach-house*. The roof, being at 45°, is the steepest we have, and the best place we have for *Strawberries*. Three or four rows, however, shade the *Peach* trees rather much, but we must keep them a little longer yet.

Regulated *Vines*, and proceeded with thinning *Grapes* in dull days and early in the morning. The late viney that had the shoots suspended some 30 inches from the glass has broken very freely, and we must now shut up and keep going slowly. There has lately been air on all night, and as much as possible during the day, and the canes never had a sprinkling of water over them. In early houses we generally moisten the canes before they swell and break their buds, but it is of little importance doing so in late houses. After the *Grapes* are set we syringe no more, but keep the floor and pathway rather damp until the *Grapes* ripen.

We saw a nice viney the other day, which belongs to John Hawkins, Esq., jun., near Hitchen, one peculiarity of which relieves it from the monotony generally prevalent in vineeries. The viney had been built, planted, and some time cultivated by the late — Ransome, Esq., who was quite at home in all such matters. The viney stands on a lofty knoll, with the ground falling from it all round. It is span-

roofed, with glass at the sides nearly down to the ground. The peculiarity is that the *Vines* have been planted in the centre of the house, grow up in bush fashion to the ridge, and then occupy about a yard of the roof on each side of the ridge. *Vines* are also planted at the sides so as to run along the sides, leaving an opening on each side of the roof for from 4 to 5 feet in width, so that the sun may reach the bottom, next the floor, of the central *Vines*. The effect is very pleasing on entering the house. The fine healthy-looking *Vines* had good bunches 2 or 3 feet from the ground, as well as at the top and in all the intermediate places. We suppose to make the *Vines* break uniformly at first, the stems from the ground to the ridge had been twisted something in corkscrew fashion. The furnace and boiler were fixed at the north end, and this end was occupied by a brick wall. The chimney goes through this wall. From against it a bunch of ripe *Grapes* had been cut, and one or two bunches of *Hamburgs* were colouring, and some bunches of *Sweetwater* were nearly ripe, whilst the bulk of the crop will not be ripe for something like six weeks, unless a strong heat be kept up. The wall makes what would have been the coldest end the warmest. Dry flowers of sulphur were laid along the pipes. We think some amateurs would prefer growing *Vines* in this manner in span-roof houses to having them suspended under the roof in the usual way.

ORNAMENTAL DEPARTMENT.

Very much the same as in previous weeks. Finished pruning *Roses*. Mowed, rolled, dug beds and borders, lined walks, borders, &c., with edging-iron. Cleaned walks in kitchen garden. Potted, planted out in temporary beds, and put in the last batch of *Verbena* cuttings, placing them at once in light soil in a frame, with a little heat beneath them, &c.—R. F.

COVENT GARDEN MARKET.—APRIL 22.

The supplies of home-grown vegetables are now abundant, and importations from the continent are heavy, but not by any means in such good condition as formerly, owing to the heat. A few dessert *Apples* and *Pears* are still to be had, also good new *Grapes*. The *Potato* trade continues dull.

TO CORRESPONDENTS.

\*\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

FLOWER-GARDEN PLAN (T. E.).—We will have the plan engraved, and publish it next week with a brief notice.

ORCHARD-HOUSE (Ignoramus).—Why did you write to Mr. Fish notwith standing our published notice? You may find some information in "Diary of the Last Week."

**FLOWER-BEDS (J. N.).**—We should prefer pairing such beds with the same planting, and if the beds are more than 4 feet in width they would tell well edged. If the gravel is so light, however, dark colours should predominate for edgings.

**VINE LEAVES (Besborough).**—The leaves should have been sent at least in tissue paper. We found no disease upon them, and but little of the warts which are generally the result of the house being kept damp and the roots wet and cold. The shrivelling you speak of we would attribute to want of root-action. Have you examined the stems and roots to see that they have not been nibbled by mice. We once had a Vine or two of which the leaves shrivelled, and we found the stems nearly severed by mice. Even for warts sulphur would do no good.

**CONSERVATORY ADJOINING DRAWING-ROOM (Hazelbourne).**—If your back wall faces the south you will not have shade enough for Ferns. You might have them on the two sides, where you propose plunging your pots, if there were more shelves there. A pretty mode would be to throw these sides into irregular little hillocks for Ferns, and cover the ground with Helvetic Moss, and have an elevated vase or two. We think for such a house as yours we would prefer large vases with creepers hanging from them, and the plants in the vases might be in pots, to permit of changing them often. This would be more artistic than plunging in borders. If the latter should be decided on we would prefer moss, and plants of Helvetic Moss could be grown to cover the other Moss as soon as the plunging was done. The climbers we recommend are *Passiflora corulea*, *Passiflora racemosa corulea*, *Tacsonia mollissima*, *Bignonia Chirera*, *Habrothamnus elegans*, and *Kennedia Maryatta*.

**INSECTS ON STRAWBERRIES (E. Wittle).**—After examining the bits of Strawberry leaves we thought we found one young, white, red spider, and there seemed also traces of thrips. The leaves should have been wrapped in something to prevent the insects escaping. For plants in bloom put sulphur on the heating medium, so that the sulphur may not be heated above 165°, and as soon as the fruit is set syringe well with clear soot water. Need we say that it is useless to write expecting a reply for the first Tuesday, when all the Number was printed before your inquiry came to hand? Friends who want answers in a hurry should write early—as soon as the previous Number is out.

**TWELVE ZONAL GERANIUMS FOR POT CULTURE (J. T. X.).**—Diadem salmon and white; Eve (Bull's), pink; Editor (Bull's), scarlet; Clipper (Bull's), scarlet; Madame Rudersdorff, salmon; Attention, scarlet; Mrs. Martin, orange scarlet; Paul l'Abbé, rose; Lord of the Isles, scarlet; Herald of Spring, scarlet; Oasian, bright magenta scarlet; Henri de Beaudot, white and carmine. Best white-flowered of the same class are Madame Vaucher, Madame Barillet, and Snowball. Geraniums with crimson in the markings, Mrs. Pellock, Mrs. Benyon.

**SOWING PEAS (A Beginner).**—It would be better to sow the late Peas midway between the rows than a foot from the Sangster's No. 1, which will do fairly for Lord Raglan, and even British Queen. They will not do so well between the rows of Veitch's Perfection, as it comes off some weeks later than Sangster's No. 1. In no case will they do so well as if sown in the open uncoupled ground. They will be inconvenient, and liable to become drawn.

**RHODODENDRON EXIMUM (G. P. C.).**—It is a garden variety. It is not scarce, but has only flowered as yet in a few places. It is a free bloomer, and being an early bloomer is best adapted for greenhouse or conservatory decoration, and though hardy is so liable, as all early bloomers are, to be cut off by spring frosts as to be of little value outside.

**DRAINAGE FOR TERRACE WALK (Pembroke).**—There are some good articles on levelling and draining in "The Gardeners' Assistant," by Mr. R. Thompson. The more open matter you put in your 20-foot path the better—say from 12 inches deep, and a drain deeper still, and about 10 inches of gravel over all. We have seen walks wear well that had very little openings made for them, some 6 inches of binding gravel put on, a slight fall given towards the sides, and the walk made so firm that all the water was taken to the sides. For lasting work we would prefer one, however, with rough open material below the gravel, and which would never be soft on the surface.

**CROCUSES DONE BLOOMING (F. G. C.).**—You may remove the Crocuses, and plant them in the garden in an open situation, for out-of-the-way corners are not suitable for ripening the bulbs. In removing them do not disturb the roots, but take up and plant with the soil adhering to the roots. It will not do to take them up and store them away in sand, for that would so weaken them that they would not bloom for some years, or very likely destroy them.

**LOBELIA SPECIOSA AND AMARANTHUS MELANCHOLICUS IN BOXES (Idem).**—Your Lobelia will do very well placed on shelves against a wall protected at night with matting. The *Amaranthus* should, after being pricked off, be kept in-doors until the middle of May, when it may be hardened off like the Lobelia. It is too late to sow *Lobelia speciosa* under a hand-glass, and have it strong for planting out. It will not bloom until very late. To bloom well it requires to be sown early in heat.

**BOXES FOR CLIMBERS (C. R. H.).**—Neat boxes of slate or wood from 24 to 30 inches square and as much in depth, will answer very well for climbers to cover your house side, if properly drained and well watered in summer. The outside of the boxes, especially if of slate, should be of a light stone colour. *Wistaria* and the *Roses* you mention will do.

**LILY OF THE VALLEY-BED (Idem).**—Lilies of the Valley should not be quite shaded, but they will do on the north side of a wall. Strong loam in the soil they like best, but they will grow in every kind of soil, though sometimes they refuse to thrive in a soil; but you cannot know this without trying.

**REMOVING GREENHOUSE (Sigma).**—Brickwork such as you would require for setting a boiler, and forming a chimney, are not removable without the landlord's consent. But all the glass work of a Paxtonian or other greenhouse structure may rest merely on a layer of bricks, and may all be removed at any time. Such a structure might be heated by a gas or other moveable stove, with an iron tube for chimney, which would also be removable.

**GLASS FOR PEACH-HOUSE (S. B.).**—We have never tried Peaches under fluted glass. We have seen them flourish under rough plate. We would, however, prefer clear glass ourselves. We wish that some of our readers who have tried fluted glass would detail their experiences. We have seen flowering plants do well under thick ribbed glass.

**FUMIGATING (A Connaught Man).**—You must fill the house with tobacco smoke on a calm evening, the ventilators being closed, and the foliage dry. Fill it so full that a plant cannot be seen through the glass from the outside. Put a few red hot cinders in a pan or flower-pot, place the tobacco dry over it, and stave the pot on an inverted pot. It will slowly but surely burn, and fill the house with smoke. If the house is large, two or more pots may be necessary. Do not open the door, nor let out the smoke. It will let itself out quite soon enough. The tobacco will burn quite fast enough without saltpetre; but you may, as you have no bellows, dissolve a tablespoonful of saltpetre in a pint of water, and steep brown paper in it until thoroughly wet, then dry it, cut it into pieces a foot long, and 6 inches wide, and roll these up lengthwise leaving a hollow space of half an inch or so in the centre, which is to be filled with tobacco. Twist one end and insert that in a flower-pot or in the soil, then set light to the other end, and it will burn out gradually. A number of these rolls will be required to fill a house according to its size.

**MELONS FAILING (Idem).**—Judging from the details which you have given, we should imagine that the leaves were scorched for want of air sufficiently early, though air need not be given so early as when the sun first shines on the glass. We never found it necessary to give air much before 8 A.M. Bright weather following a continuance of dull weather is the only time when Melons are benefited by shade, and then it should be slight. Four plants are not too many for a frame 6 feet 4 inches, by 6 feet, though quite sufficient. Particulars of Melon culture, sufficient for every practical purpose, were given in our last volume.

**VEGETABLE MARROWS AND RIDGE CUCUMBERS (Idem).**—Your situation is a bad one for both, but they ought to do better. You sow too early, and the plants become stunted in growth ere they are planted out. They ought to grow away from the seed without receiving any check. The middle of April is quite soon enough to sow the seed. When up put two in a pot, and when established remove to a cool house or frame, planting out in the second or third week of May. Dig out a hole and fill it with a good barrowful of hot dung, and cover with 6 inches of soil; place the hand-glasses over the hills, and plant out, keeping close and well watered for a few days, then gradually admit air by tilting the lights, and as the plants grow raise the lights so as to allow the shoots to run outside. Remove the lights altogether in June, after they become well established, or by midsummer, and water copiously in dry weather.

**GRAFTING ORANGE TREE (Assaye).**—You may graft the Orange tree during this and next month; the best time being when the stock begins to grow. The most certain mode is inarching, and the next tongue or whip grafting, leaving the base of the graft so long beyond the point of union that its end may be placed in a vial of water. The best variety yet introduced for eating is the Tangerin, and it does well in a cool greenhouse. We were unable to tell from the small leaf sent, whether the tree is an Orange or Lemon, it being a miserable fragment, but the stock whatever it will do.

**REGULATING TEMPERATURE (S. M. L.).**—The easiest and cheapest plan by which you can regulate the circulation in the greenhouse connected with your stove, is to procure two small elbow pipes, made of zinc, galvanised iron, or tin, so that the outside of this short pipe shall just fit into the inside of those which you now have. The pipes may be 7 or 8 inches long each way, and the one end should go in to the pipe, and be fastened securely there and made water-tight with paper and white lead, or white lead and tow, the other end standing upright, and these upright pieces should be fitted exactly with wooden plugs. Nothing can be more simple. You may have the upright part of this pipe even higher, and then when you want no heat in the greenhouse, you may have the water only high enough for the flow in the stove. If you liked you could regulate the heat in the stove in the same way. If the flows from the cistern had proceeded from the bottom, it would have been easier still, only blocking up the holes where heat was not wanted. Without any pipes you might have an elbow wooden-block with the upper end high enough to move the lower end out and into the pipe. This must fit the pipe exactly at the outside; but a small opening, by pulling the plug a little out, will give plenty of circulation. A tap with a hammer will make all right when no circulation is wanted. A simpler arrangement at first would have saved all the trouble.

**PROPAGATING COMBERS BY CUTTINGS (C. E. H.).**—A large number of Combers may be increased by cuttings. The first week in May is a good time for putting the cuttings in; they should be cut slanting through the joint, not straight across as cuttings are generally made. By cutting them in this way it leaves a much larger surface from which roots can be emitted; the cuttings may be from 2 to 7 or 8 inches long. Prepare a mixture of peat, leaf soil, loam, and silver sand in equal proportions, place 2 or 3 inches of broken crocks in the bottom of the cutting-pots, then fill the pan up to within an inch of the top, taking care to press the soil in firmly. Fill up the remaining space with sand, make this firm by pressing it down with the bottom of a flower-pot. Care should be taken in putting in the cuttings to press the soil firmly about them, and the base of the cutting should rest on the bottom of the hole made by the dibber. After the cuttings are put in they should be well watered to consolidate the sand about them, they should then be placed in a close frame where no sun can shine on them. Keep them close for six weeks or two months, only taking the lights or bell-glasses off for a few minutes to sprinkle them, or for the purpose of cleaning the glasses. The pans most suitable for the purpose are those about 9 or 10 inches deep.

**AQUATICS FOR ARDEN POND (Roley).**—For the deepest parts, *Nuphar lutea*, *pumila*, and *advena*; *Nymphaea alba*, *nitida*, and *reniformis*; *Vallisneria spiralis*, *cordata*, *ovata*, and *nymphoides*; *Rumex hydroclapathum*; *Typha latifolia*; and *Iris pseud-acorus*. For the shallower parts, *Richardia scythopica*; *Alisma plantago*, *natans*, *lanceolata*, and *ranunculoides*; *Calla palustris*; *Butomus umbellatus*; *Acorus calamus*; *Hottotia palustris*; *Caltha palustris*, and the double variety; *Ranunculus hederaceus*, *obtusifolius* and *aquaticus*; *Apogoneton distachyon*, and *angustifolius*; *Cardamine pratensis*, *amaris*; *Sagittaria sagittifolia*; *Monyanthe trifoliata*; *Hydrocharis inornatus-runs*; *Stratiotes aloides*; *Myriophyllum spicatum*, and *verticillatum*. For the edges, *Samolus regalis*; *Lobelia Dortmanna*; *Decarpis urundinacea*, and its variegated form; *Myosotis palustris*, and *emplota*; *Veronica beccabunga*; *Lysimachia thysiflora*, *L. nemorosum variegatum*; *Valeriana officinalis*; *Lythrum salicaria*; *Eupatorium cannabinum*; *Epilobium angustifolium*, and *hirsutum*. We do not know where they may be obtained, but many are British plants, and all in cultivation at the present time, though we cannot name a place where they are grown for sale. Nurserymen should advertise such things.

**LINING MELON-FRAME (B. A. P.).**—There will always be danger of the steam from the lining of dung passing through the openings or joints of the loose bricks and injuring the plants within the frame, more or less according to its rankness. To prevent its doing so, the joints of the bricks above the soil inside the frame should be stopped with mortar, leaving the outside unstopped, which will allow of the heat of the dung passing into the wall, heating the bricks, and heat will be radiated from their surface into the atmosphere of the frame without rank steam. If the heat be very strong, and from fresh fermenting materials, it may be necessary to stop up the crevices on the outside with mortar, to make sure that the rank steam is not passing into the frame. If it does, so to any extent it will materially affect the foliage, and, if very rank, completely destroy the crop. We have known walls built of loose bricks, the inside being pointed with mortar, and then white-washed, answer very well indeed, and give more heat than when the bricks were laid in mortar.

**RAISING CARNATIONS FROM SEED (G. R.).**—Prepare ordinary seed-pans or pots as follows:—Drain to one-third of their depth with pieces of pot or rough cinders, and on this place one-third more of the rougher parts of the compost, which should be light turfy loam, that from curves a year old being preferable, mixed with one-third of its bulk of well-rotted leaf mould. Fill to within half an inch of the rim, and make the surface even. Scatter the seeds regularly over the surface, and cover with fine soil sufficiently deep to hide them. Water and place in a frame or house with a gentle heat, or failing this under the lights of a cold frame, or in a warm situation protected from heavy rains. When fairly up remove to a cold frame if raised in heat, always keeping the soil moist but not very wet, and when sufficiently large to handle pot off singly into small pots, or prick them out in a sheltered situation. Keep shaded for a few days until established, and in September plant out 1 foot apart in beds of good rich soil in a sheltered yet open situation. They will bloom next year.

**FOSTER'S WHITE SEEDLING GRAPE (A Lady Subscriber).**—It is a white Grape, but has not a muscat flavour. It ripens in a greenhouse about the same time as the Muscadine, and is superior to that variety. When ripe the skin of the berries is of a clear amber colour. Its blossoms set freely, and the bunches are large and handsome. We know of no reason why it would not inarch on the Black Hamburgh.

**SEEDLING TANGERINE ORANGES (An Old Subscriber).**—Tangerine Oranges will come true from seed, and, therefore, grafting will not be required. Of course, the seedlings will bloom without grafting, that being only practised to perpetuate varieties. As to the mode in which the operation is performed, see an answer to another correspondent.

**MANAGEMENT OF BULBS (J. A. H. S.).**—It would not be safe to take your bulbs up before the second week in May; if they are then taken up you may plant them on the spare border in very light sandy soil. As soon as the foliage becomes dry take them up and spread them thinly on a shelf or bench in a dry airy shed let them remain there for a few weeks, then pack them away in drawers or boxes. Primula, Calceolaria, and Cineraria, sow at once; Camellia, Azalea, &c., pot as soon as they have done flowering.

**PAMPAS GRASS CULTURE—CANNAS (H. J. F.).**—We should think no better soil could be found for Pampas Grass than yours. The situation is also good. The richer you make the soil with well-decomposed manure the better will the plants grow. Plant them out at once. The aspect will suit them well. The same soil and situation will suit the Cannas, only they must not be planted out before the second week in May, unless they are dry roots; that being the case, they may be planted out at once.

**ROSE PRINCESS MARY OF CAMBRIDGE (Paul & Son).**—It is a beautiful flower, colour pale rose, with a bright pink centre; something in the style of Duchess of Sutherland, but a much fuller Rose. If it maintains its present character it will be a decided acquisition; and as forced Roses are not generally so good as those in the open air, we should imagine that it will be even better by-and-by.—D, Deal.

**EVERGREEN SHRUBS FOR BEDS ON LAWN (Amateur).**—The outside beds would look very well if planted with dwarf-growing evergreen shrubs. You do not say whether your garden is much exposed, or whether it is a damp soil or dry. If the sub-soil is moist the following would do well:—some of the dwarf-growing kinds of Rhododendrons, Leucums, Azaleas, Vaccinium, Gaultheria, Epigæa, Andromeda, Menziesia, or Irish Heath, Ericas of sorts. Place a few spadefuls of chopped peat or bog around each plant as they are put in. Different kinds of Lilliums would look well if planted amongst them. Herbaceous plants may also be planted with advantage. If it is a dry loamy soil and the situation an exposed one, the following plants would be most suitable for the beds:—Aucuba japonica and some of the newer kind, such as A. japonica femina, Berberis, or Mahonia aquifolium, Deutzia gracilis, some of the best and most distinct kinds of variegated Hollies, Magaëlia conspicua, M. purpurea, Pyrus japonica, white and scarlet, Skimmia japonica, Spirea callosa, Weigela rosea. These may all be kept as small plants by constantly pinching-in their tops. Standard Roses would look well planted amongst them, their stems would be hidden by the evergreens, the tops would then appear just above the evergreens, giving the bed a very pretty appearance.

**MULCHING FLOWER-BEDS—APPLYING LIQUID MANURE TO ROSES (F. C.).**—The mulching is applied to the surface of the beds after the plants are put out. An inch or so of short manure placed on the surface checks evaporation, and, consequently, there is less necessity for watering, it affords food to the plants without making them too vigorous, and is not so stimulating as when manure is mixed with the soil. Roses, like all plants, do not like strong applications of manure water. It should be applied weak and at every alternate watering, or once or twice a week during the growing season. We do not know of an edging plant raised from seed that will do in the place of Lobelia.

**NAMES OF RHODODENDRONS (Gunton Park).**—It is R. Falconeri, one of those discovered by Dr. Hooker in the Sikkim-Himalaya, at an elevation of 10,000 feet above the sea. (Lady L. Coles) Yours is R. Windsorii, discovered by Mr. Booth in the mountains of Bootan, at elevations of from 7000 to 9000 feet.

**NAMES OF PLANTS (De Foix).**—1, Pteris aquilina; 2, Cyrtomium falcatum; 3, Nephrolepis tuberosa; 4, Litobrochia vesperilionis; 5, Selaginella, apparently casia. (M. D.)—Pelargonium radula. (W. M.)—Erica (an unnameable scrap); Garrya elliptica. (Eskdale).—Hardenbergia monophylla. (P. S.)—Pittosporum undulatum. It is not hardy. (A. W. C.)—Plants cannot be named from bulbs alone: we must see the flower. (J. K's S.)—Your plants were so carelessly packed that all but one of the numbers were loose when they reached us. No. 3 is Gnidia inberbis. Two others in flower are Primula denticulata and Pittosporum Tobira. The rest not being in flower we cannot undertake to name. (Eucharis).—1, Medicago orbicularis; 2, Cornus mas. (W. N. B. and Leighton B.)—It is utterly impossible to name plants from single leaves or scraps of leaves. We might guess at dozens of things and be wrong after all. (W. N.)—1, Pulmonaria officinalis; 2, Muscari racemosum; 3, Lamium maculatum; 4, Leucocjum aestivum.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending April 22nd.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.
			Air.		Earth.				
	Max.	Min.	Max.	Min.	1 ft. deep.	2 ft. deep.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

A DAY AT DEVIZES, AND WHAT I SAW THERE.

My visiting acquaintance among friends of like taste to myself is on the increase, thanks to "Our Journal," which being a centre in which similar rays meet, also brings the rays closer together. This is well; for we fanciers are apt to get smiled at by friends in general, thought peculiar, odd, eccentric, and we are, like all good things in this world, very frequently scattered wide apart: so there is all the more reason why we should meet, and at poultry shows we do, which is one of their many benefits. But it was not a poultry show that brought me to Devizes, but of that presently. "When Greek meets Greek, then comes the tug of war;" and when fancier meets fancier, then comes a pleasant hour or two; we are like freemasons, and we understand each other's language. Now the uninitiated vex us,

good-tempered fellows though we be. Thus we are asked to show our stock, and we hear, "What pretty little birds to be sure!" Pretty little birds! that all!—birds with so many properties and distinct beauties! Oh! how blind is ignorance. Or, comes the question, "What is that queer-looking fowl, if fowl it be, with yellow and feathered legs, and odd walk?" "A Brahma cockerel, madam." "Dear me! I have heard of Bramah locks, but never of Brahma fowls. What do you call that poor little Pigeon with a red wart round its eyes, which look inflamed?" "That is my prize Barb Pigeon." "How funny. I have heard of a barb horse before, but never of a Barb Pigeon." But a truce to such friends, let me now tell of a meeting between friends who appreciate, because they understand, the beautiful birds. Now I had been invited by an excellent judge and successful exhibitor of poultry and Pigeons, resident at Devizes, to inspect his birds, especially his turn-crown white Fantails. I accepted the invitation with pleasure. I had never been at Devizes since coaching-days, so scarcely knew

where I was, as a new road out through a hill had been made to reach the town from the station; indeed, poor "WILTSHIRE RECTOR" might have lost himself (would there not have been lamentation at Hilltop Rectory if he had?); but no fear, as my host kindly met me. A corner is turned and I am once more in the fine old market-place, and I exclaim on viewing that noble space and its surroundings, "What a picture of an old county town is Devizes!" There, before me, stands the monument to Ruth Pearce of lying memory; around are the picturesque houses, here one with a fair Grecian front, there steep gables, some red-tiled and honeycombed gables, such as Gilbert White noticed in Sussex; I remember several at Easebourne, that pretty village, dear to me, adjoining Cowdray Park, and lying near the town of Midhurst.

But I am at my new friend's house, and soon we visit the loft, the best place in which I ever saw Pigeons confined. It was the top storey of a very long factory-like building, 100 feet long by 20 wide, with large windows all round, with the sun streaming in—a capital thing for Pigeons, for they delight in sunshine. My eye at once fell upon a red-pied Powder cock of singularly good shape and fine carriage; and soon after upon an old bird, with his crop nice and globular as seen from the back. What a fine loft for Powders, for they can almost unimpeded take their long sweeping flight. Some of them were white, and so owl-like were they that they looked as if they by right were the lawful tenants of the old building. Now for the Fantails: they were, I am happy to say, all white, and very good birds they were. Of the pair of turncrows imported from India, the hen was particularly charming. As she fronted me with her slender head and neck surrounded by the tail feathers, which formed a rayed crown to her head, I own my preference was to the English birds without the turn-crown, as the shape of the Fantail's head does not seem to require it; but there is room for all opinions in the world provided they are harmless. On the floor I was glad not only to see a good water supply and plenty of gravel, but pans for growing green food in. Then I examined the nest arrangements, which, to avoid the possibility of rats, were near the ceiling, thus also causing the birds to take more exercise; also the loft was not marred by the presence of any inferior birds, which is well, for the best eat only as much as the worst. I trebly enjoyed this loft from the evident happiness and health of the birds. Round and round we sauntered, I picking out my favourites, and admiring, and criticising.

We descended at last (N.B.—A very long ladder, no gouty foot must venture up). Well, just at the bottom were strutting about some Black-breasted Red Game fowls, very good, and of Fletcher's strain. I am reminded, however, that "dinner waits," but unlike Mrs. Gilpin I cannot add, "and I am tired." Now, after dinner it had been arranged that I should visit two other lofts and poultry-yards; so we cross the market-place and arrive at another fancier's, where I am also very kindly welcomed. The Pigeons had been kept in so that I might inspect them the better. Ah! I know what variety—they are far above me—I hear the merry rattling coo of the Tumbler. Surely a chapter might be written upon the different cooing of Pigeons, as Mr. Dixon wrote a chapter upon the different crowing of cocks. For instance: there is the deep coo of the Powder, who plays the big drum in the columbarian band, then the Trumpeter, then the lively shrill fife of the Barb; but of all cooing commend me to that of the cheerful Tumbler. My friend's, a friend in every sense, were in breed the right medium between the coarse-shaped Roller and the (for flight) too delicate Almond, just, in fact, what high-flying Tumblers should be—pleasing near at hand from their trim form, and charming in the air. I at once marked out what I considered the best pair. "Ah! I had those from Mr. Brent:" so "Our Journal" met me at Devizes. By my wish they are let out, and up they go, all save one wise hen, who perhaps will lay to-morrow, and whom no pocket-handkerchief waving can frighten into the air. Up they go—higher—higher—higher. Now they are close together; then one tumbles over clean and clever; then they are all falling in the clear atmosphere, tying knots charmingly; then all up together. While I look, lo! they are all at it again. Certainly high-flying Tumblers are great sources of pleasure. I never could do long without a flight; even among the Grampians

I had my Tumblers. I suppose I must have some again some day.

Next the fowls. Some are in wooden houses fronted with net—White Bantams and Malays. I hear a voice near me saying quietly, "A certain 'WILTSHIRE RECTOR' calls Malays ugly birds." Oh! what a dig in my poor ribs.

"Needles and pins, needles and pins,  
When a man writes his trouble begins."

But the stab was given so gently that I winced, but did not either scream or faint; the kind look took away the pain, if pain there were. In a back garden I found a troop of some twenty Malays, and as they charged past me at a quick canter they reminded me of either camels with their necks stretched out and long legs, or some irregular cavalry, say Bashi-bazouks. "I have been a fancier many years, 'WILTSHIRE RECTOR,'" "May you be many more," said I; "Nature never tires;" and I pointed to the garden and greenhouse, and poultry and Pigeons. But I must hurry on to see another fancier, for the railway is an awful despot; time, tide, and trains wait for no man. "Get behind me or walk," growls the engine. Further on into the town, and I found a dull yard enlivened by Pigeons. Then a look at St. John's Church, with its noble tower, and that roof from off which the lead was stripped to mould into bullets when the brave little town was besieged by the parliamentarians. Being on the direct way between London and the west, Wiltshire suffered much in the civil war, and more particularly Devizes. I have a peep into the Town Hall, evidently of the Georgian era; indeed, a full-length picture of George III., and one of his Queen, hang on the walls. In the council chamber I noticed a likeness of a former and favourite M.P. for the borough, also a picture of the former Town Hall, showing, also, the market-place. On the landing near I noticed on a panel the borough arms, bearing the date 1606. But I must hasten. Next, a walk through "The Brittox," an odd name for a street, meaning, perhaps, "Larracks;" then to another church, St. Mary's, and a distant peep at the castle, now restored; then home again, driven in by the cold, and snow is again falling. The dessert is renewed to the amount of one glass of wine to warm us after the cold walk. "By the way," said I, "is there time for me to take a second look at your Pigeons? I like a second look to correct opinions if necessary." "Oh, there is time, and I shall be delighted to go up again—only too happy." So we again sought the long loft, and looked at and handled several birds; they seemed old friends, and I never saw better birds, especially the Fantails. A cup of tea followed and a poultry chat, in which I had the pleasure to agree with my host on most points, and then back to the station.

Oh! Devizes, I liked you well; I liked your most un-manufacturing-district look, I liked your old-world historic appearance, I liked the friends I met there, and some day I hope to go there again. Such, good reader, was my "day at Devizes."—WILTSHIRE RECTOR.

#### THE APPOINTMENT OF POULTRY JUDGES.

AFTER the expression of Mr. Beldon's opinions in your Journal of last week, I think it unnecessary to bring forth further arguments to induce him to resign. To find that he not only disagrees with, but is absolutely ignorant of, a rule setting forth one of the principal objects of the Club, will, I have no doubt, not a little astonish his brother members, especially Mr. Zurhorst, who gave his opinion on the subject in so decided a manner a few weeks back. If the rule is rescinded, as he appears to think, I am very glad, but I am afraid such is not the case.

Whilst acknowledging that he sells "a large quantity of poultry," Mr. Beldon objects to the name of dealer, but as he buys birds wholesale and sells them retail, I do not know what else to call him. I know several instances in which he has bought up the stocks of retiring exhibitors in a single lot, and sold them again in pens or single birds to suit purchasers. I have known him for several years, and have always looked upon him in that light; and it is worthy of remark that he did not object to the name until he was called upon to resign, although it had been published a full month in your Journal.

Mr. Beldon is mistaken in supposing that I considered his showing in his daughter's name an additional reason why he should relinquish the office; the reason why I introduced her name was to show that the birds really belonged to Mr. Beldon. My additional reason for thinking that he ought to resign was, because I did not think that the owner of "the most successful yard in the kingdom" should be one of the persons to appoint the Judges. Still, when he enters his birds in Miss Beldon's name he commits a breach of the rules of every Show at which he exhibits; for do not the rules require the entries to be made in the name of the proper owner of the birds?

In conclusion, I confidently hope that Committees will consider the advice given in my last letter, and appoint the Judges themselves, and then the question of Mr. Beldon's resignation or otherwise will be of very little moment, especially to—A LOOKER-ON.

### ROOKS THE CAUSE OF PIGEONS DESERTING THEIR HOME.

In November last I erected an excellent Pigeon-house, replete with every comfort and every advantage as to its aspect, warmth, size, height from the ground, protection from vermin and cats duly considered. In this house I placed six pairs of Pigeons—well-bred Bald-head Tumblers and one pair of beautiful Mottled Trumpeters. After due confinement they were all set at liberty, and continued to be quite at home all through the winter. They laid, sat, and were prospering well, until one fine morning in the middle of February one disappeared for two or three days, but returned again; soon afterwards two or three birds did the same, and at last all the Pigeons during March took these freaks into their heads, until my dove-cote became destitute of all but the Trumpeters. These remained until about a week ago; they, too, are now gone—gone altogether, notwithstanding inquiries, offers of reward, &c., so that I am convinced they are not within miles of their home.

I find that Pigeons have a great fear of rooks, and as I have a large rookery not far from the dove-cote, there is no doubt that when the rooks began to come to their old haunts to build the Pigeons were terrified, and at last so much so as to leave their home and altogether disappear. The absence of birds of prey, as hawks, which might have caused the mischief, confirms still more strongly my firm conviction, that if there is a rookery within a quarter of a mile of a dove-cote the Pigeons within it during the building-time of the rooks will mostly, if not all of them, leave their homes; whether they mean to return remains still unproved to—CHANTICLEER.

### DUBLIN SPRING POULTRY SHOW.

(From a Correspondent.)

The above Show was held in Kildare Street, Dublin, on Tuesday the 18th inst. and three following days; and though the weather was most unfavourable there was a numerous attendance of visitors. We were pleased to see so much improvement in the different breeds. *Dorkings* headed the list, and among them were some very good specimens. There was a splendid pen of Silver-Grey chickens, the property of E. W. Boyle, Esq., which we have no hesitation in saying it would be very difficult to beat at any show. In *Spanish* twenty-seven pens competed; the third-prize pen of old birds contained two hens that left the others far in the shade. In *Spanish* chickens we have seldom seen so good a pen as that which obtained the first prize. In *Brahmas* Mr. Boyle carried all before him, and we never saw better. In *Cochins* F. W. Zurhorst, Esq., had it all his own way, and they left nothing to be desired. The first prize went to Whites, the second to Silver Cinnamons; and if we may be allowed a remark, the prizes should have been reversed. The Cinnamon cock was a wonderfully good bird. *Game* were only poorly represented. In *Polish*, White-crested birds were successful. In *Hamburgs* there was no merit. There was no class for *Bantams*. Mr. Zurhorst showed a nice pen of *Crève-Cœurs*.

The prize pen of young *Turkeys* was very fine. The first-prize pen of *Aylesbury Ducks* was really good, having splen-

did bills, and being very fine. In *Rouens* there were some good birds, Mr. Boyle's being remarkably good. The first-prize drake was the finest we have seen for some time. In *Geese* Toulouse carried off all the prizes. Mr. Dawson, of Hopton Mirfield, exhibited a beautiful pair of Egyptian *Geese*, which were commended. Mr. Boyle's first-prize gander weighed 30 lbs. The pens used were Turner's, of Sheffield, and they gave every satisfaction. The following is a list of the awards:—

*DORKINGS* (Silver Grey).—First, Second, and Third, C. P. Leslie. *Chickens*.—First, R. W. Boyle, Dundrum. Second, R. P. Williams, Dublin. Third, C. P. Leslie.

*DORKINGS* (Coloured).—First, R. P. Williams. Second, R. W. Boyle. *SPANISH*.—First, A. Comyns. Second, Miss De C. Drevar. Third, R. W. Boyle. Highly Commended, De C. Drevar. *Chickens*.—First, R. W. Boyle. Second and Third, A. Comyns. Commended, W. Perrin; R. P. Williams.

*BRABMA* FOOTRA.—First, Second, and Third, R. W. Boyle. *Chickens*.—First, Second and Third, R. W. Boyle.

*COCHINS*.—First, Second, and Third, F. W. Zurhorst. *Chickens*.—First, Second, and Third, F. W. Zurhorst.

*GAME*.—Prize, C. H. Peacock. *Chickens*.—First, Miss Langtry. Second, C. H. Peacock.

*POLANOS*.—First and Second, Miss De C. Drevar. Highly Commended, R. P. Williams.

*HAMBURGH* (Pencilled).—First and Second, Mrs. Kemmis.

*HAMBURGH* (Spangled).—First, R. P. Williams. Second, C. H. Cooper.

*CRÈVE-CŒURS*.—Prize, F. W. Zurhorst.

*TURKEYS*.—Prize, R. W. Boyle.

*GESE*.—First, Second, and Third, R. W. Boyle. Commended, W. Dawson, Hopton, Mirfield.

*DUCKS* (Aylesbury).—First, R. W. Boyle. Second, R. P. Williams. Highly Commended, A. Warburton.

*DUCKS* (Rouen).—First and Second, R. W. Boyle. Highly Commended R. P. Williams.

Mr. Stanton, of Dublin, officiated as Judge.

### STORIFYING—INFLUENCE OF SEASONS ON THE PRODUCTION OF SWARMS.

I BEG to return my thanks to "A RENFREWSHIRE BEE-KEEPER," for his friendly comments upon my storifying proceedings last summer, and hope that his observations may prove serviceable both to myself and others. I have been long aware that bees will gladly avail themselves of accommodation afforded in the shape of a nadir; but have also feared that such accommodation would, if offered to a supered hive, divert their attention from the super. Perhaps "A RENFREWSHIRE BEE-KEEPER" will kindly detail his mode of procedure in a future Number of your Journal.

As long as I had English bees to deal with, I found a single super was almost always sufficient to prevent the issue of a swarm; but with Italian bees, both storified hives and also first swarms have almost invariably sent out swarms, though the latter have always been nadired, and sometimes supered into the bargain.

Observation has convinced me that the fecundity of the queen bee is much greater than has been generally supposed, and that the population of a hive is frequently much restricted from want of proper accommodation. Dr. Bevan says wet seasons are generally productive of swarms, and dry ones of honey; but last summer demonstrated that dry seasons may be productive of swarms, if they also prove unproductive of honey. My three first swarms last season were—May 15, a natural swarm; May 16, an artificial swarm; and May 18, an artificial swarm. These all progressed very well for about a fortnight, collecting honey from the apple trees and sycamores (which were covered with a great profusion of blossoms), so that the hives were nearly filled with comb by the end of May, and contained a good deal of sealed honey. June was excessively dry, and upon examining the swarms at the end of the month I found all the combs almost full of brood, with very little honey, nearly every available cell containing either sealed or unsealed brood. The hives were all nadired and were full-sized Woodbury-bar, or bar and frame-hives.

All these swarms sent out swarms in spite of nadirs; and one of them did so although it was both supered and nadired, after all the royal cells had been once excised. This hive after the return of its swarm worked very vigorously, and continued in pretty brisk action after all the other hives had almost ceased to work. I believe they were gathering honey from honeydew. They yielded 8 or 9 lbs. of very fine-flavoured honey from a shallow super, but it was dark-coloured although stored in virgin comb. The bulk of the honey I obtained was very much lighter in colour.—J. E. B.

## HIVES AFFECTED BY DAMP.

My bees live on the north-east coast of Norfolk in flat-topped straw hives, placed on a sheltered little lawn surrounded by tall trees, though not overhung by them. The stands are 18 inches from the ground. Last summer I took but little honey. Only two hives out of six swarmed; I prevented the others swarming. In September and October I fed all with barley-sugar, and placed glasses on the top to avoid damp. When they were weighed, in the beginning of winter, the eight hives each weighed from 20 to 31 lbs., boards and hives. When I examined my hives in the beginning of February I found some hives with only a few bees, some empty, only one at all strong. Only two have been saved, and all the hives but the strong one were damp and mouldy; some were well supplied with honey and pollen. How am I to account for damp destroying so many, and yet one hive not being in the least damp, though placed with the others, and treated exactly like them? Is the sea coast a bad place for bees? Should I cover my hives with any cement? How can I further guard against damp? These bees came from a village eight miles from London, where I had excellent success, and I hardly ever lost a hive in winter; but since the change to Norfolk the bees have degenerated.—M. H. M.

[The mischief you describe appears to have arisen from internal moisture, probably aggravated, if not entirely produced by, the means intended to obviate it. If the flat tops of your hives are made of wood it will go far to explain the mystery; if not we should be disposed to refer it to condensed moisture running from the glass into the interior of the hives. When glasses are applied in this manner during the winter they should stand either in feeding pans or in circular metallic troughs, specially adapted to the purpose; but, in the case of hives made entirely of straw, we believe them to be quite unnecessary. That one hive should escape uninjured under exactly similar circumstances is not at all unusual, just as one member of a family frequently remains healthy when all, or nearly all, the rest are stricken down by disease. The sea coast may not be so favourable a locality for bees as your former residence, but we see no reason why they should not prosper, although not, perhaps, to so great an extent.]

## RANCIDITY OF BUTTER.

I HAVE no doubt that the bad flavour of "COCHIN'S" butter was caused by decayed vegetable matter of some kind. Some years ago the butter produced on a neighbouring farm was found to be of bad quality in consequence, it was said, of the cows being out of condition. It being autumn and severe weather setting in, the cows were housed for about ten days, and the next churning was of the usual good quality. A few days of fine weather coming on the cows were again turned out to grass. The butter was again of an unpleasant flavour; the cause of the bad flavour was then thought to be the cows eating grass that was in a state of decomposition, as it often is after frost or severe weather. It could not be from the cows eating tree leaves of any kind, as the fences round the field were all stone walls, and there was not a tree within two hundred yards of the field except one small tree with a stem about 2 inches in diameter. Butter and milk will be found to have a bad flavour if the cows are allowed to eat decayed vegetable matter of any kind. I have seen a cowkeeper who was noted for good milk, cut up his turnips by hand, and in doing so cut off every piece that was decayed. Decayed garden refuse of any kind eaten by cows will cause the butter to be bad, especially if there be any onions in it. A farm labourer in cleaning up his master's garden wheeled into the farmyard a barrow-load of onions, the milch cows ate them all up, the result was butter not fit to eat. Cows will often give bad butter if fed on hay and grass. An old farmer now deceased would never allow his cows to eat grass and hay both on one day. All kinds of horned cattle will often suffer from indigestion, and be swollen almost to bursting, if allowed to eat decayed vegetable matter. A simple remedy in such cases is a handful of common salt dissolved in warm water, and given to the cow or other animal. Turnips and hay will produce bad butter. I have not, like your correspondent "T. G.," angled in the Washbourn, but I know that in the lower

parts of Wharfedale, when cows are fed on turnips, straw is given to lessen the taste of the turnips. The taste is always bad when the cows feed on hay and turnips. A farmer who often milks upwards of twenty cows, assures me that his butter is always bad when the cows are fed with locust beans, so bad that he has given up churning.

I hold an opinion that ergoted grasses will give a bad flavour to milk or butter. The last year produced ergot (*Spermodia clavus*, Fries) in abundance, and of large size; on roots of *Lolium perenne* (perennial rye grass) I picked spurs nearly an inch long. In districts where ergot abounds there will always be a great number of barren cattle. I am informed on good authority, that a cattle breeder for exhibition last year lost £300 from abortions caused by his cows eating ergoted grasses. Will some one of your scientific readers of THE JOURNAL OF HORTICULTURE, have the kindness to tell us the best way to get rid of this pest to agriculture? Drainage is not always a sure remedy, as I find it growing in well drained land.—ROBT. SMITH, *Dewsbury*.

## OUR LETTER BOX.

EGGS FAILING TO HATCH (*S. H.*).—We should be more disposed to attribute the failure of the eggs to the unkind weather we have had than to any other cause. Thousands of eggs have failed from being frost-bitten. Try a sitting of those laid since the change of weather. Test them at the end of a week, and if they have no life in them procure another cock.

FOWL'S NECK SWELLING (*W. B. D. A.*).—Such swellings as you mention are more common among Spanish than any other breed. They should be taken out when they first appear. When they harden they become full of cheesy matter, and pervade the whole system. It is a bad case.

CHICKENS DYING IN HATCHING (*D. O.*).—We have no doubt your chickens die in the shell from the eggs being too dry. For a week before hatching they should be wetted every morning, or at any time when the hen is off the nest. Failing this assistance the inner membrane of the egg becomes as hard, tough, and brown as Indian rubber. Few chickens can get through it. When the hen is off dip your hand in water and wring it over the egg freely.

DORKING'S FACE SWOLLEN (*Old Ealing*).—It may be only a cold, but the swelling you mention is like the beginning of roup. Wash the swollen part with cold water and vinegar. Give castor oil, a table-spoonful at a time, and feed on bread and ale. It is disputed whether it is contagious or not. It is so, undoubtedly, to sickly birds, but healthy ones seem to meet it with impunity. If it is the only bird affected and not very valuable, put her away.

PRESERVING EGGS (*W. T.*).—We keep eggs for months in very good condition, even for the breakfast table, by putting them in wetted lime in a common bread-pan, alternate layers of lime and eggs. They will keep for a long time if they are covered with butter as soon as they are laid.

REDEUBING A GAME COCK (*Old Subscriber*).—You run no risk whatever in redeubing the cock. Use a pair of very sharp clipping scissors, and cut from front to back, as close as possible, without laying the skull bare.

FOWLS DISORDERED (*Reigate*).—There is no reason why your fowls should be sick so far as we can judge, unless they are overfed. "Scraps from the kitchen" is a wide term, and may easily mean more food than is good for them. Keep them for a few days on meal mixed with milk, and feed sparingly.

SOIL OF FOWL-YARD (*P. W. R.*).—You will find the smell disappear. Sprinkle charcoal powder over the surface, keep it well raked, and you may burn some pieces of lime an inch or two below it.

Egg-PASSAGE PROTRUDING (*E. B. P.*).—It is more than probable the pullets have not laid till now. The first egg, and sometimes up to the third and fourth eggs are laid with difficulty, often causing bleeding and protrusion of the egg-passage. The other hens are attracted by it, and pick and pull it; hence death. If there be any difficulty after the first, the cause is internal fever, and the cure, moderate feeding and plenty of green food, lettuce if possible. All difficulty in laying is prevented if the fowl can be watched, and the egg passage thoroughly lubricated with a feather dipped in oil. It is no disease.

GOLDEN-PENCILLED HAMBURGS (*Hamburgh*).—The ordinary food for other chickens is that which Hamburgs require, boiled eggs, bread and milk, bruised wheat, table scraps, fat and skin chopped fine; curd. Chickens require beer when they are hatched very early in the year, or when the cold is severe; also during strong easterly winds. They prefer beer at all times, but they do not always want it. When a comb turns black, it is from stoppage in the crop or elsewhere, or from eating poisonous or poisoned food. Give a table-spoonful of castor oil every other day for a week. The birds cannot be in health with a black comb.

BANTAM LAYING SOFT EGGS (*A. A. E. S.*).—The secretions are at fault, and the desire to eat the eggs shows a disordered state. Give a table-spoonful of castor oil twice, at twenty-four hour's interval. Put some false eggs—very hard ones—in her nest. If you find she strains in laying dip a wing-feather in oil, and lubricate the egg passage with it. This will remedy all.

TOULOUSE GEESE (*L. C., A. Subscriber*).—Toulouse Geese are marvellous layers, but we consider them non-sitters. Yours has laid fifty-three eggs, but one of ours has laid above sixty eggs, and seems inclined to keep on.

ARRIVAL OF THE NIGHTINGALE AND CUCKOO (*Bishopstoke*).—The Nightingale precedes the Cuckoo. In the south of England the former arrives in the first half of March, but the Cuckoo not until after the middle of April. The dates of arrival vary a few days in each year.

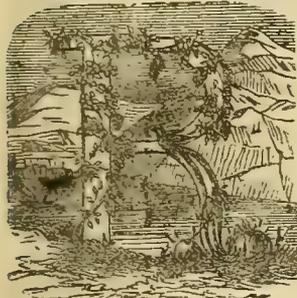

TEACHING BULLFINCHES TO PIPE (*John Farr*).—Look out for some nests next month, when the young ones are ten days or a fortnight old, take them and bring them up by hand, put them into a covered basket, and after each meal play or whistle the tune over to them which you wish them to learn. Continue the same for five or six months.—B. F. B.

WEEKLY CALENDAR.

Day of Month		Day of Week	MAY 2-8, 1865.			Average Temperature near London.			Rain in last 38 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock after Sun.	Day of Year.

8	M	Laburnum flowers.	58.9	39.0	48.9	16	21 4	32 7	17 5	15 3			13	3 42	128	

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 61.2°, and its night temperature 39.2°. The greatest heat was 84° on the 6th, 1862; and the lowest cold, 20°, on the 2nd, 1855. The greatest fall of rain was 1.26 inch.

ROCKWORK.

ROCKWORK as it occurs in Nature is of two kinds; the one with, and the other without water. Each is furnished with appropriate plants, but the best examples are where the rocky views are accompanied with water.

Though water is very acceptable, and in many ways desirable in forming rockwork, yet it is often

introduced without any absolute necessity, for the absence of water does not constitute a deficiency in rockwork, some of the most picturesque forms of this occurring on mountains, where it is mostly clothed with plants. On the other hand, rockwork accompanied by water is the more beautiful; but good rockwork may be formed without water, yet water is materially improved by a judicious accompaniment of rockwork. It is, however, absurd to form rockwork on the margin of water and occupy the cultivable portion with plants that grow on lofty, dry hills, as is too often the case. Pope says, "The principles of landscape gardening consist of—first, the study and display of natural beauties; second, the concealment of defects; third, never to lose sight of common sense." Marshall cuts it short and embodies it all in three words, "nature, taste, and utility." Loudon admits or advocates two principles, one of "design or relative beauty," and "imitation or natural beauty," both very distinct, and the one perfectly inconsistent with the other. This is precisely the case with rockwork in gardens. There is no principle in general, but a mixture of tastes that do not comprise the rules contained in "the unity of the whole and the connection of the parts." I have no liking for little rills, diminutive rocks, and tiny lakes, for above everything this rule should be observed, "never to attempt more than can be carried out upon a scale sufficiently large to have a natural effect." Placing a variety of features in a small space so as to prevent any semblance of utility, there being no natural beauty and no concealment of defects, may add to the intricacy, but as a work of art it is contemptible. It is not meant that no rock should be smaller than that of Gibraltar, no lake less than Windermere, nor any stream smaller than the Danube; but rockwork is not to be formed by upsetting a cartload of stones here, there, or anywhere, nor a pond made that would hardly afford swimming-room for a pair of water-fowl, or a rivulet for the purpose of putting over it a rustic bridge. The greatest oversight of the present age is the crowding of many features where there is only space to exhibit a few to advantage. Every feature should be such that a man of taste would have to "look up" at it, for if he does not do this he will "look down" upon it.

Rockwork to appear in all its grandeur should be bold, rough, and extensive. It should form a feature in the distance, have a bold outline, have broad and flat ledges, fissures deep and shallow for the growth of plants—in fact, have the appearance of a rock, at one time solid, but broken into fragments by storms or time. Diminutive rockwork does not show what it is meant for, and nothing is more paltry than a mound of earth covered with a few stones for the sake of growing a small number of plants, though it may answer that purpose as well as if the rock were 100 feet high. It is better to see a large rock split into few parts and not far asunder than to make up a rockery of small stones or a hundred fragments. Large plants on large stones or pieces of rock are natural; the plants on or amongst small stones are not only at variance with the character of the rock itself, but look too artificial. Small plants on a small rockery do not mend the matter, for however small, they look far too large for the places assigned them, whilst they fail to hide the deception. The greatest fault of most artificial rockwork is, that it is made on too small a scale, affording no feature at a distance, and when you come upon it it can be looked down upon and over instead of the observer having to look up to it, unless, indeed, it be a series of nooks, arches, and counterparts of ruins that give an appearance of an old building, where the Ivy may love to cling, but the Alpines be out of place, and too large for their stations. In some other cases rockeries can only be compared to a cartload of stones emptied in a heap. True it is, that a rock of two stones, or even bricks, or clinkers, will grow a plant as well as if it were as high as a mountain; but in landscape gardening a rock should never be so low as to permit of a view over it. Rockwork, however, is not necessarily a part of landscape gardening, and unless a necessity appear for its introduction, and unless it be judiciously placed and managed, and of a respectable size and elevation, it would be far better left out.

The reasons for desiring rockwork are—first, a wish to grow rock plants; second, materials for the formation of rockwork which would be in the way were they not so appropriated; third, a large broken mound or hillside that is every way a defect, which being converted into rocks would form a pleasing feature; fourth, the presence of a deep ravine which it is desirable to retain; fifth, excavations, as old gravel-pits, quarries, &c., not easily filled up; and, lastly, a wish for alpine scenery. With these the temptation to construct rockwork is great, and it is still greater if there is water near. The evils are—first, sameness and diminutiveness, which destroy the effect of the picture and the rock-like appearance; second, regularity of outline or smoothness, which is destructive of grandeur; third, selecting an unsuitable situation; fourth, constructing rockwork without attending to the surrounding scenery.

Perhaps the best field for the study of natural rockwork in Derbyshire and Devonshire, where there are some magnificent examples. We may find rocks of all sizes in

these and many other parts of the kingdom. Wales, for instance, abounds in them, and so do Scotland and the Isle of Wight, but we nowhere find an assemblage of small stones piled one upon the other, like by far the largest proportion of the rockwork of modern gardens.

As regards the desire of growing rock plants, there is no objection to them, provided the rockwork is not made so as to be destructive to some other feature. To form a rock on a level piece of ground is simply ridiculous—it can never appear natural; but it may be made to appear so by excavating a hollow to be filled with water, and throwing the soil taken out into a mound of irregular form, building a part with rock quite steep, another flat, with large pieces of rock cast here and there as if by accident rather than design, some on their ends, others on their sides, some forming a natural arch, some leaning and about to fall, and all uniting to form a rough bold scene. In forming the rockwork care must be taken that the earth is solid beneath and the crevices, also, filled with soil where it is desirable to introduce plants; but cover the stones as little as possible, otherwise the rocky character will be destroyed, and the rockwork will present the appearance of a mound covered with stones. It should be elevated, and so much so as not to be looked down upon. If water is introduced it may come trickling down from a fissure in the rock, drip over stones, and fall over some placed perpendicularly into the pool or lake beneath, and here it is desirable to have the rockwork in the shade so that it may be accompanied by Ferns and plants that delight in shade and moisture. The pool itself may be surrounded with grass or lawn, or have a rocky edge where the smaller aquatics may be grown. Instead of dripping from the rock into the pool beneath, the water may be conveyed through a rocky passage or channel strewed with stones, and planted with plants that thrive in shallow water, or grow in moist ground. It may lose itself in a fissure of the rock, appearing again at another point. It may again find its way into a hollow and there form a lake, and there may be a rocky path near the lake with a rock rising abruptly from it, or the water may wash the base of the rock, the latter rising from three sides and forming a sort of amphitheatre, the summit of the rock being bold and rugged, and the plants in the fissures and on the ledges in large clumps; shrubs, and even trees being introduced in order to give the effect at a distance which small plants have close at hand.

Rockwork may also be formed by sinking a path, throwing the soil into irregular mounds, and forming arches in some perpendicular part where the walk rapidly descends or ascends, so as to appear as if the stones forming the arch had fallen from the heights, and being thrown upon each other formed the arch accidentally. This kind of rockwork may be made very pleasing, only do not use too many and too small stones in its construction. Perhaps the best example of this kind is in the Regent's Park gardens, where the passes with their rocky sides and the rocky arches have but one fault, and that is they are too small, though happily contrived in other respects.

As to the other points, the second is simply a repetition of the first, except inasmuch as it is a conversion of materials rather than providing a receptacle for plants. The third is easily remedied, providing irregularity of outline, boldness of feature, and avoiding all appearance of sameness are kept in view. The sides may be rocks and the summit a grassy slope, or clothed with nobler verdure, and the rock may appear again above that, which is perfectly natural, for in mountainous places rocks protrude half-way, and appear in patches here and there up the whole face of the mountain. Fourth, a deep ravine or valley may be much improved by converting the rougher parts into rockwork, and clothing the less steep; in some places having rock on both sides as if the ravine had been created by a severance of the earth, and taking advantage of a projection to introduce a rocky crag, which may be backed up with shrubs not with a view to hide anything beyond, for that is bad, but to give the idea that the earth had been rent and the part on the one side severed from that on the other, which should be clothed in like manner, leaving the rock prominently in view. The ruin of a building appearing as if demolished in the general convulsion, may be introduced with great effect. The paths should not be marked, though they may be introduced to a certain extent to afford access

to the different parts, but they should be of the rudest kind and appear as neglected as possible. If dressed walks are made, one taking a circuit of the whole and permitting of the principal features being seen only once, or if twice from a different point of view, will be sufficient, and this walk should be concealed as much as possible. If it were possible to bound the view by high rocks, crowning them with hanging woods would have a fine effect, unless a stream passed through the ravine, when the high rocks with overhanging woods should not bound the view, but be situated on one side of the stream washing the base of the rocks, so as to afford a clear view of the open country, the stream widening as it passed through green meads and groves. This will be the open end of the ravine, or the view from it. If there is no stream the view may likewise be open, though bounded by some object in the distance, or the view will be barren-looking. The view in or up the ravine should be different. It may consist of a high rock having a cascade in the centre, with a richly-wooded background, or the ravine may lose itself at the foot of a mountain, partly wooded, with here and there a piece of rock projecting. If a stream pass through the ravine or rocky glen it will be considerably improved by placing rough stones in parts, and introducing rocks to divert the course of the stream should it run straight.

For forming caves and subterranean passages great facilities are afforded by quarries and gravel-pits. The sides should be broken down to what we may term a sloping crag in one part, leaving a perpendicular wall in another, just as it may contribute to the general effect. The crags should be bold, with here and there broad shelves and deep fissures. Some parts should appear as mounds of earth clothed, however, with shrubs and dense foliage, and grassy slopes may be introduced to relieve the crags and connect the rocks with the wooded parts. The shady and moist places are peculiarly well adapted for Ferns. Form the whole so that there may be no blemishes to be hidden by planting. Avoid ruins—at least, do not form them of unhewn stones, and do not throw arches to caverns with hewn stones, or even place rough stones one upon the other systematically, but tumble them together; let the crags, interstices, and ledges appear real; above all, let the character be that of a rock—distinct and varied, bold and rugged, no even surface, but uneven; the whole forming a pleasing and noble object.

Lastly, Alpine scenery. This is too much to attempt unless the ground favour such a disposition. In level ground it cannot be produced without great labour and expense, and it is better to let it alone. The examples which we find in many nurseries and public gardens are not worth copying, nor is anything to be learned from them except the evils to be avoided. Imagine a stream running through rocks rising from the water to a height of only a few feet, with Heath, so rarely found as rock plants, on the margin of the water; and find me a lake not cut in two by a rustic bridge, serving only to spoil an otherwise fine sheet of water. Heaps of stones piled one on the other on level ground in front of mansions, on lawns, in pleasure grounds, or parks, are not necessarily rockwork. If a rock is wanted, copy nature. There rocks are of all sizes and forms, but not in the middle of grass fields. Further, note a fountain in the centre of a garden, truly a work of art, surrounded by rockwork, and form your own opinion as to whether they are not two very distinct and incongruous objects, the one belonging to the polished or gardenesque, and the other to the picturesque or natural. Wherever a rockery is attempted, it should be screened from the rest of the ground by well-disposed shrubberies, so as to give that rockwork a distinct character, forming a pleasing contrast to the more regular portion of the grounds. Though barren rocks appear in nature, or plain rocks with but one or two kinds of plants to adorn them, yet we are not bound to imitate these, but rather to bring together many beauties of natural rockwork in one place, and hardy plants from all parts of the world, in order to secure diversity and the best general effect, that some parts may be admired for their richness in plants, others on account of the rocks.—G. ABBEY.

**VEGETABLE FLANNEL.**—Those of your readers who take an interest in the manufacture of vegetable flannel from the *Pinus sylvestris*, may like to have the information that since about

1860 there are two establishments near Breslau, in one of which Pine leaves are converted into wool, while in the other, for invalids, the waters used in the manufacture of Pine wool are employed as curative agents. The process for converting the Pine needles into wool was discovered by Mr. Pannowitz. In the hospitals, penitentiaries, and barracks of Vienna and Breslau, blankets made from that material are now exclusively used. One of their chief advantages is that no kind of vermin will lodge in them. The material is also used as stuffing, closely resembles horse-hair, and is only one-third its cost. When spun and woven, the thread resembles that of hemp, and is made into jackets, spencers, drawers, and stockings, flannel and twill for shirts, coverlets, body and chest warmers, and knitting-yarn. They keep the body warm without heating, and are very durable. The factories are lighted with gas made from the refuse of the above manufactures.—C. W. H.—(*Athenæum*.)

## ON THE UTILISATION OF NIGHT SOIL APART FROM SEWAGE.

(Continued from page 307.)

But I am losing sight of the pamphlet. Mr. Wilmot, at page 6, refers to two others written by the Rev. Henry Moule, entitled "Health and Wealth," and "Manure for the Million." I have never seen them, but they first drew Mr. Wilmot's attention to the subject, but, unfortunately, machinery was suggested, which, let me add, for the million, would be likely to prove a failure, yet as to the objection as to the difficulty of procuring dry earth, I think that would be easily overcome. The habit of the cat and some other animals is happily adverted to to prove that we cannot err in copying nature, and that where there is a will the poor dumb creatures point out to us a way. Then follow some remarks by Mr. Wilmot against sewage, which I hope he atones for at page 9, where he says, "I am now only speaking of the million, and do not propose to interfere with the higher classes in private houses, comparatively small in number, who may still wish to employ water as an agent until they can be satisfied it may be dispensed with," and he owns the difficulties of anticipation in these matters to exceed those of reality. Returning to the dry ashes again an appeal is made to medical men, and then the example of the Chinese is quoted, and some most sensible remarks are made upon the barracks of European soldiers in India. I cannot pass over a paragraph at page 12, for the advice is most valuable:—

"The system I advocate, as applied to country villages, is most simple in operation, as may be seen in some houses in the village near to which I reside in Derbyshire; but supposing other villages to be unwilling or unable at once to adopt it, much may be readily done in the abatement of nuisances: We will suppose a privy or cesspool to have become offensive, this is caused by water from some channel or another having got into it in undue proportions. First stop this channel, and then apply a few barrowfuls, or a cartload or two, of ashes or dry earth, and the whole can be removed and utilised at once without danger; and if, in future, the owners of the vault and privy would prevent water getting into it, and throw daily into it, or even weekly, the dust and ashes obtained from their houses, they would soon have a store of valuable manure for the garden. The system might also be employed most advantageously in small farms, and more so even in large ones.

"We will suppose the small farmer to have no spare shed under which he could place his manure heap, but he might possibly have a spare stall, cow or horse, or he might erect a thatched shed. In this let him place daily the contributions of his cows, horses, and pigs, together or separately, under cover, and daily place over them the dust obtained from his house, or his cinders or dry road scrapings, or whatever of dry road soil his farm affords, and in a few months he would have a collection of valuable manure exceeding in quantity anything he had before anticipated, and his straw would be all saved for chopping up; of course the large farmer might make more extensive and beneficial arrangements on the same principle. I was lately discussing this subject with a clergyman, who told me that he had for years placed the riddled dust of his ashes in a

corner of his yard, without cover, day by day, and had poured on it daily all the slops of his house, and soapsuds, dish-washings, &c., and his gardener and farming man had been most willing to use the heap up in his garden and farm, especially when mixed with other composts, but he told me he had remarked that in rainy weather the heap became offensive. This only showed the simple necessity of a shed or cover for his heap."

In following paragraphs the futility of using vegetable substances—such as sawdust, which will not deodorise, and cinders, which will, but did not, from careless superintendance—are pointed out, also where earth-closets would prove peculiarly suitable; and in a few closing lines Mr. Wilmot allows a strong bias against sewage once more to appear, and in this respect I beg to differ with him. When town sewage is allowed to run into our rivers, then I grant him it is in opposition to the laws of economy and nature. Nevertheless, in a sanitary point of view, the prohibition of cesspools and the free use of water in towns are conducive to health, and so soon as we can convince people that sewage is a valuable manure, and that 80,000 gallons of liquid can be pumped by steam power 100 feet high at a cost of 1s., the whole difficulty will vanish, and by-and-by local authorities will only be too likely to become embarrassed with applications for the sewage. It is not merely as it relates to waterclosets, but there is the chamber-ley, soapsuds, and so many other manurial ingredients held in suspension in the house sewage of the upper and middle-class residences in the country, and of factories, barracks, workhouses, and prisons, that it ever must be a great saving to conduct it to the land by its own gravity in a liquid state, and it seems to me that there is no choice in the matter as regards towns from the increasing use of waterclosets. In towns, too, the inhabitants could never be supposed to become interested in the earthing-over process in a cultural point of view; besides, conveyed at once upon the land no deodorisation would be required. The ground is the only perfect deodoriser, naturally operating very rapidly in purifying the sewage, for the manurial matters held in suspension are at once abstracted as it filtrates through the soil. I find that almost as soon as it is applied to this garden all smell disappears; and is not this in point of fact performing artificially and at once what in the dry-manure system has to be done naturally by the rain? We have had both systems at work here for years to our great advantage, but there is this distinction in practice—the earthy matter is cast out of the closet once a-year, and mixed with the compost-heap just before it is wheeled on to the garden to be worked into the ground in the trenching process, after the manner pointed out at page 169; but the sewage from the tanks is used frequently, and it is never now allowed to remain in bulk long enough to arrive at the putrefactive stage.

Mr. Wilmot adds a postscript to his pamphlet in consequence of an issue of a third edition of Mr. Moule's "National Health and Wealth," from which he learns that that gentleman's principle has been adopted in some of the gaols and barracks in India," and also that "the Chinese although they save and utilise everything, do not in the first instance apply dried earth as a deodoriser. This discovery is due to Mr. Moule." Seven years ago, in Vol. XIX., page 368, in an article stating the effects of syringing the foliage of fruit trees, in a state of blight, with hot diluted ammoniacal liquor, I wrote the following:—"Analogous to the application of ammonia to the leaves of trees, there is a practice in China. It is pointed out as follows by the *Times*' special correspondent, writing from Hong Kong, on the subject of Chinese agriculture:—"Grass grows rank only upon graves. One or two buffaloes, two or three goats, a breeding sow, ugly long-legged fowls (called Cochin-Chinas in England), and a flock of ducks and geese, are the live stock of a Chinese farm, which maintains a hundred labourers. Stable-yard manure is scant. Human ordure is collected with care in numerous open earthenware pans, where passers-by can contribute their offerings, both offending the senses and poisoning the air. In the suburbs, each house has its cesspool; in the country, each cottage its inviting latrine. At Ningpo two immense pans lie opposite to the entrance door of the first native merchant of the city, awaiting the payment of 2000 dollars, which is the price of their removal. To an Englishman, who visits

their country, these manure traps constitute his first and last impressions of never-ceasing horror. Boats convey this produce through the inner waters, and anchor close to you at night, only to remove for a consideration. One Englishman, in disgust, paid thirty dollars to a fellow to move on. This manurial treasure is, according to a Chinaman's way of thinking, too precious to be worked into the ground. *It is sprinkled over the leaves of the plant (italics my own).* Burnt haulm and straw of the Cotton-plant only are delved into the soil. The Chinese transplant every root of rice by hand, and each root gets its little blessing of the above liquid; but give an English farmer or gardener 'some 1000 acres of vegetable loam of an unexplored depth, waterways, reticulation of ditto for flooding-purposes, labour at 4d. per day, abundance of sunshine, periodical rains, large markets, cheap communication by tidal creeks, and what corn and pot herbs he would produce, to say nothing of tea, sugar, cotton, silkworms, silk, and Mulberry leaves, our friend Giles would have to scratch his head a little before he could start on a race to overtake these Chinamen, who are 4000 years of practice a-head of him.' Still, I continue to imagine "our friend Giles" manages a good many things better, albeit, those "immense pans" do bring in the Chinamen "a great deal of money." It would almost appear by the price of it, that our northcountryman must have resided as a cultivator of the soil in the neighbourhood of Ningpo, when he gave the following warning, "Never, Sandie, never, above all things, never get into debt; but if ever you do, *let it be for manure.*" I know our own country is scarcely half cultivated as it ought to be, because we allow the best of what is due to the land, to go to waste, and my advice to people likewise is, that if they ever do allow themselves to get into debt, let it be for erecting waterproof earth closets, and liquid manure tanks; for the very good and continuous interest that these will presently return, will enable the debtor to pay off his creditor, and leave something to spare.

I am glad to find that so able an adviser as Mr. Wilmot has taken up the subject. His pamphlet is most worthy of extensive notice and circulation amongst residents in the country, cottagers particularly, for it is the poorer sort that we want to reach in simple words. In 1852, in a cheap monthly periodical of that day, called "The Cottage Lamp," I explained in a series of papers the necessity of attending to these matters; and, as the subject is exciting deserved interest just now, I shall feel happy if, by what I have said, it may prove a means in a still greater degree of directing public attention to the matter, for the feature seems so new, and yet the plan with myself is so old. Both in the wet and in the dry state I have for thirty years been utilising the excreta experimentally, and I have not arrived at my present conclusions without some failures, and a great deal of planning, filtering, observation, and obloquy. What we should have done in the last dry season without our water and sewage tanks I do not know. The wells of Woodstock can be counted on one's fingers' ends, and what the diminished supply of water of our filthy little river held in suspension it is difficult to say, but I am glad to state that we were not under the necessity of drinking it, for these premises are now self-sustaining. The water tanks catch sufficient water from the roofs of the houses and outbuildings to supply our wants, and it is filtered for drinking and cooking purposes. The overflow from the water tank is conducted away by the old sewage drain. In the shape of sewage, all the water used for household purposes is applied to the garden, and with what comes from the earth-closet, and other matters, it is sufficient to keep the ground in a state of high cultivation. Nothing offensive runs from here on to our neighbours' premises, nor into the river; for that I take credit to myself, and am satisfied, and the rector feels the satisfaction in having improved the house and grounds, both for himself and for his successor.

In conclusion, I throw out the following suggestion for as much as it is worth:—As Government advance money for land draining at so much per cent., would it not also be worth their while to consider whether the national purse could not be made to contribute towards the abatement of a great and increasing national evil, by the advance of money at interest to those who, not having the means to make them, yet would be glad to possess sewage-tanks and

earth-closets? In one case as well as the other, for the permanent welfare of the land, I think it is reasonable to encourage men to put their shoulders to the wheel when they can see that it is for their interest to do so.—UPWARDS AND ONWARDS.

### THE NEW ROSES.

THE genial spring weather which has followed the long and tedious winter has brought on a healthy and free growth in all kinds of plants that have been dormant for a long time in consequence of the continued cold. This is especially the case with Roses. For many seasons past so promising a start has not been made as at the present time, thus raising the hopes and expectations of careful cultivators in a more than usual degree. Longing as we all are to see again the lovely forms of our favourites, but not without apprehension on account of the various accidents of weather, disease, and the attacks of insects, the desire is still stronger to obtain early information on the new additions we are, or ought, to make to our rosery, and to know what purchases should be made with as little delay as possible, that propagation may be proceeded with in the ensuing season.

For the purpose of satisfying myself as far as possible on this subject, and to afford assistance to amateur friends, I took advantage of the Easter vacation to pay a visit to Mr. William Paul's nursery, at Waltham Cross. The whole stock is now in fine healthy-growing condition, and rapidly pushing into bloom.

Taking them in the order of inspection:—

First, Madame Emile Boyau is a very pretty light variety, which may be described as rosy flesh, changing to blush; of good size and delightfully fragrant. It has the habit and constitution of Baronne Prevost.

Glory of Waltham is a magnificent flower, surpassing in every respect its parent.

Leveson Gower. Its large, full, crimson flowers and vigorous habit will render it a general favourite. One of the best of the season.

Princess Lichtenstein, as a white Hybrid Perpetual, seems likely to be a great acquisition. Judging from the habit and foliage, it is superior to Louise Darzins. There not being an expanded bloom at the time of my visit I am unable to offer an opinion of its merits.

Elizabeth Vigneron is rosy pink, very large, and full, resembling Lælia, but surpassing it in form and freshness of colour. The blooms shown to me were truly beautiful.

Prince de Joinville, a large, showy, light crimson rose, will prove a useful decorative garden Rose.

Celine Gonod, pink, with a beautifully incurved petal; outer petals paler than the inner. Fine and perfectly globular.

Auguste Rivière has beautiful bright reddish carmine flowers. Perfectly distinct; but as the majority of the plants seemed to indicate a defective constitution, further experience will be necessary to decide fairly on its merits or otherwise.

Triomphe des Français may be considered a good Rose, both from its brilliant crimson flowers and vigorous habit. Probably one of the best of the season.

Michel Bonnet has bright rose flowers, large and full; but I did not observe any superiority in this variety over older kinds of similar colour and form.

Madame Charles Verdier, on the other hand, is one of the best. Its flowers are fine vermilion rose, very large and full.

Souvenir de Bernardin de St. Pierre (what a name for our gardeners!) answers the description given of it—namely, flowers varying from crimson to violet, centre red. I doubt whether it will suit the prevailing English taste.

Achille Gonod is a seedling from Jules Margottin. It must be good if it beat its parent, which I am not at present prepared to affirm that it does. It is, however, a truly beautiful Rose, with very fine foliage, and will be deserving a trial.

Rushton Radclyffe bids fair to be one of the gems of the season. Its bright red colour added to its bold, globular, perfect form, with imbricated petals, give it a prominence in company with other kinds that attracts immediate attention to it. Whether in the show-box or on the living

plant, which is the best place to view it properly, it will long retain a place both on account of its own merits and for the respected name with which it is associated.

Charles Margottin will be another valuable addition. Although of the race of the well-known Jules Margottin, it has more substance in petal and greater elegance of outline, while it possesses all the brilliancy of the fine carmine with fiery red centre. This Rose will be one of the best.

Duke of Wellington will be sure to please; notwithstanding it is one of the many scarlet Roses that of late have been introduced, it has the distinctive character of tint in being slightly shaded with maroon. Somewhat approaching Louis XIV., but not so dark, and different in shape.

Prince Eugène Beauharnais is another of the scarlets, of which it will be necessary to see more before venturing an opinion.

Maréchal Niel has not been exaggerated as regards habit, &c., but none of its blooms were sufficiently open to afford a correct idea of its beauty. It has, however, been exhibited by Mr. W. Paul, and favourably noticed.

Souvenir de William Wood and Xavier Olibo were not open. Favourably as they have been spoken of, they are both surpassed in habit and foliage by Dr. Lindley, which is not yet ready to be sent out, but will undoubtedly prove worthy of the name of the venerable botanist.

Here I must stop for the present. Our amateur friends may thus see that they will be safe with Rushton Radclyffe, Charles Margottin, Glory of Waltham, and Madame Emile Boyau. Doubtless a few months' experience will bring out other points of excellence not yet noticed, and several among those not named in this account may be found to be good.—ADOLPHUS H. KENT.

## ROYAL BOTANIC SOCIETY'S SHOW,

APRIL 29.

THE last Spring Show for the season was held on Saturday last, and notwithstanding a chilly east wind the attendance of visitors was very good. The day, however, was fine with bright sunshine, but in temperature offering a marked contrast to the July weather experienced in the earlier part of the week.

As a whole the Show was in no way inferior to its predecessors, while the objects exhibited presented greater variety. Roses again formed a principal part of the display, and it is hardly possible to conceive anything finer than the pot plants shown by Mr. Turner and Mr. W. Paul. It was evident at a glance that the contest for the first place lay between these two exhibitors, but to decide which would carry off the palm was not so easy, the specimens in both collections were so fine. Mr. Turner took the first prize with Gloire de Dijon, Baronne Prevost, Souvenir de la Malmaison, the blooms of the last very large, Souvenir d'un Ami, Charles Lawson, and Général Jacqueminot. Mr. W. Paul had the second prize for Madame Boll, Souvenir de la Malmaison, Lælia, Souvenir d'un Ami, with somewhere about fifty blooms more or less expanded, Sénateur Vaisse, and Celine Forestier. Messrs. Paul & Son were third. Mr. Wheeler, gardener to Sir F. Goldsmidt, Bart., Regent's Park, was the only exhibitor in the Amateurs' Class. A numerous collection in excellent bloom came from Messrs. Lane. Roses sent out since 1863 were shown in threes. Mr. Turner was first with Lord Clyde, Alba rosea, white with a rosy tinge in the centre, and Mrs. Wm. Paul, glowing in colour. Next came Mr. W. Paul with Jean Goujon, very large and full, rose, Vainqueur de Goliath, very bright red, and Bourbon Madame de Stella, bright rose. The last named, Alba rosea, and Madame Alfred de Rougemont, which was not so good as we have generally seen it, were exhibited by Messrs. Paul & Son, who were third. From the same firm came several boxes of cut blooms, containing excellent examples of Rev. H. Dombrain, fine colour, Princess Adelaide, a fine pale yellow Tea, Charles Lefebvre, and many others.

Pelargoniums for so early in the season were excellent. Mr. Turner, Mr. Wiggins, gardener to W. Beck, Esq., Isleworth, and Mr. Weir, gardener to Mrs. Hodson, The Elms, Hampstead, took equal prizes in the Nurserymen's and Amateurs' Classes. Mr. Turner had Desdemona, Beck's

Amazon, Beacon, Sir C. Campbell, W. Bull, and Pescatore. Mr. Wiggins, Beadsman, Plène, Princess Mathilde, Roseum, very bright and showy, Empress Eugénie, and Madame Reiset, cerise with maroon spot. Mr. Weir's plants consisted of the Fancy varieties, were from 2½ to 3 feet across, and in very fine bloom. The kinds were Attraction, Celestial, Queen of Roses, Acme, Carminatum, and Jenny Lind.

Collections of Azaleas in small pots were exhibited by Messrs. Lane and F. & A. Smith, the former having also a collection of hybrid Rhododendrons, while Messrs. Smith had a new Rhododendron called Queen of England with white flowers 4 inches in length by at least as much across, and five in a head. A first-class certificate was awarded for this. Mr. Parker, of Tooting, likewise exhibited several plants of his charming large-flowered, blush variety Countess of Haddington.

Of Auriculas Mr. Turner had examples remarkable for their vigorous trusses and large pips of Mr. Marnock (Turner), Sir Isaac Newton (Strong), Headly's George Lightbody, Negro (Turner), Bessy Bell (Spalding), and Sophia (Spalding); in addition to which he had a fine collection containing Lightbody's Meteor Flag and Fair Maid, Waterhouse's Conqueror of Europe, Popplewell's Conqueror, Turner's Webster, Dickson's Duke of Cambridge, a charming variety, and several others, with large pips. Mr. Butcher, Camberwell, and Mr. James likewise exhibited good sixes. Two new Alpines from Mr. Turner, Titian and John Leech, both very fine, particularly the latter, which is a bold flower, were awarded first-class certificates; and Master Hole, a rich maroon self, and Rev. J. Bramhall, green-edged, had second-class certificates. Robert Trail, grey-edged, came from Mr. Butcher, but did not receive an award.

Of other objects stands of Pansies were shown by Mr. Hooper, of Widcombe Hill, Bath, Ayres, Biggleswade, and James; Calceolarias of a fine strain by Messrs. Dobson & Son and James; Cinerarias by Mr. Wiggins and Mr. James; Amaryllis by Mr. Parker; Begonias by Mr. Wheeler; flowering and ornamental-foliaged plants by Messrs. Williams, F. & A. Smith, Wheeler, and Stone; Palms by Mr. Bull; and Ericas and a large plant of the ornamental yellow-flowered Genista Everestiana by Messrs. Low.

Foremost among rare plants were four beautiful Alpines from Messrs. Backhouse, of York, whose collection of such plants is probably the richest in the country. These were *Andromeda hypnoides*, a native of Lapland, not much higher than a moss, and bearing charming little pendulous white flowers with a red calyx; *Primula ciliata* from Switzerland bearing numerous bright purplish crimson flowers and having a very brilliant appearance; *Narcissus juncifolius*, with yellow flowers, found in stony pastures on the Pyrenees; and *Primula farinosa acaulis*, from Cronkley Fell, Teesdale, Yorkshire, having pale lilac flowers produced close to the surface of the soil. For these a first-class certificate was awarded. Mr. W. Paul had a similar award for *Raphiolepis ovata*, a Japanese plant, which was noticed in the report of his nursery in our last volume for its thick leathery dark green foliage, but now bearing several large racemes of white flowers, the plant being only 18 inches high. *Deutzia crenata flore pleno*, noticed at page 306, and very ornamental by its numerous white drooping flowers, also from Mr. Paul, was awarded a medal. Mr. Bull sent a numerous collection, and received first-class certificates for his remarkable Hose-in-hose *Mimulus*, for *Aubrietia purpurea variegata*, and *Salvadora persica*, all of which have been noticed in previous Numbers; also for a Rhododendron called *Thibaudiensis*, with tubular orange flowers, *Primula intermedia*, and *Woodsia polystichoides Veitchiana*. From Mr. Williams came *Gymnogramma Parsonii*, *Peperomia arifolia*, *Anthurium magnificum*, with deep green silver-veined leaves, *Asplenium alatum* and *phillipense*, and *Phœnicium sechellarum*, a Palm with noble foliage—one of those grown in Belgium for baskets in rooms—all of which received first-class certificates, and several other interesting novelties. An *Auricula* called *nigricans plenissima*, with very double flowers and nearly black, and *Petunia Blotch*, with a large rosy purple and white flower, a very promising variety, were shown by Messrs. Smith, of Dulwich, who likewise exhibited several new Azaleas, of which Richard Cobden and Mr. Marnock were desirable varieties. *Cineraria Dark Beauty*, a

very good deep rosy crimson self, was shown by Mr. Wiggins; and a white-flowered *Hydrangea japonica* by Messrs. E. G. Henderson, who received a first-class certificate for it, also hybrid *Verbena Ariel*, with rosy lilac flowers, and which, being of very dwarf habit, is likely to be useful for bedding. *Aubrietia græca*, with pretty purplish-lilac flowers, exhibited by Mr. Thompson, of Ipswich, received a first-class certificate; and a similar award was made to Mr. Turner for his red *Bougainvillea* and for *Fancy Pelargonium Sunrise*. Lastly, some well-filled flower-vases were shown by Miss Williams, of Holloway, and the Conifers exhibited before the last Floral Committee at Kensington by Mr. Ayres, of Biggleswade.

The conservatory, we may add, was gay with Azaleas and other flowering plants, whilst the grounds were in their usual good keeping.

### SALT APPLIED IN EXCESS.

HAVING last winter a quantity of waste salt, sweepings of a bacon store, I had it spread over the kitchen garden and two empty beds on the lawn intended for summer bedding plants, and a nice mess it has made. The first sowing of Peas came up only in patches. I find where missed lots of round bits of rotten pulp. The second sowing is not up after four weeks, and I find them green and whole, some germinated, others not, but very salt. Of other seeds there are no signs as yet, but the weather has been extremely dry and hot.

The two flower-beds not being needed until May, I sowed with annuals to lift into the borders to replace bulbs, &c., or to be pulled up when interfering with bedding plants, these seeds have not appeared. They consisted of *Clarkias*, *Nemophilas*, *Candytufts*, &c., though some seeds sown elsewhere have nearly all appeared.

What should I do? Will the salt hurt *Verbenas*, *Geraniums*, and *Calceolarias*, put in next month? May I expect rain, if it ever will rain as in the good old times in these parts, to wash the injurious excess of salt down out of the way of doing mischief? In the hope of this having been somewhat accomplished already, I have resown Peas in the same ground, for I believe the salt was liberally spread over all the unoccupied space of the kitchen garden. Peas, Parsnips, Carrots, Onions, Radishes, &c., are possibly all killed, perhaps not. Do you think it likely? In any case I am not likely to try another experiment of the sort. I intended the centre of a bed for a very fine large *Cineraria maritima*. I suppose the salt will not hurt that.—PRETTY PICKLE.

[You remind us of a farmer whom we knew in Essex, who tried salt as a manure for Potatoes. He put in the sets by means of a dibble, and then had the holes filled with salt. His Potatoes shared the fate of your Peas, &c. As a manure salt should not be applied at the rate of more than twenty bushels per acre; but even that we consider an excess. Ten bushels applied to that space annually is far preferable. The heavy rains of the year will probably wash down the excess in your soil, but we would not trust to that. We would trench the ground fully two spits deep, bringing the lower spit to the surface. We would not try even *Cineraria maritima* in a soil so pickled until it was trenched as we have advised.—EDS.]

### MY PLANTS,

AND HOW AND WHERE I FOUND THEM.—No. 2.

“What! March again?”

“Ay, with all speed. I hate the crowded town;  
I cannot breathe shut up within its gates,  
Air,—I want air, and sunshine, and blue sky,  
The feeling of the breeze upon my face,  
The feeling of the turf beneath my feet,  
And no walls but the far-off mountain-tops,  
Then I am free and strong,—once more myself.”

BEFORE I started upon my expedition, I armed myself with three most necessary adjuncts—a large basket, such as they make in Staffordshire, and which are both pretty and strong; a trowel for the more obstinate roots, and, perhaps, rather a novel implement to my botanical readers, but which answered my purpose admirably for extracting the more

delicate Ferns from between the loose stones of which these walls are made—a large screw-driver! This may provoke a laugh from the theoretical, but not from the practical botanist who has sought to disengage, gently and carefully, the tiny fibres of the delicate Ferns which cling to, and insert themselves between stones, which, piled one upon another in many places in North Staffordshire, form an inexpensive and durable protection to the fields or roadside. The varied and numerous recesses thus formed shelter many a fragile plant.

There are two pieces of wall near the village of Upper Team, which are full of the loveliest specimens of *Lastrea Filix-mas* possible. I feel most culpable when I think of the ruthless manner in which I extracted root after root from this natural fernery; but I was constantly fancying some new and wonderful discovery was in store for me in this hide-and-seek home of fairy plants. As with that “faire” lady of the old, old time, temptation was strong, and like her I thought that to possess was to be made wise, like her, I, also, was doomed to disappointment, the specimens being immature fronds of *Lastrea Filix-mas* in every stage of development, and merely varying in size or form according to the sterility or fruitfulness of the soil from which they sprung; and here I may mention how much anxiety, disappointment, and trouble these aforesaid Ferns give the tyro in botany. Their innumerable freaks, their change of shape, feature, and size, although really belonging to the same family would warrant the belief that they were the descendants of old Proteus. The *Athyrium Filix-fœmina*, or Lady Fern, is, perhaps, one of the most capricious; but whatever form it takes each variety has some peculiar beauty. How often has my husband, ever anxious to bestow pleasure, been saddened in his eagerness to present me with some new specimen, by my sorrowful decision that it was only a variety of “those deceitful *Filix-fœminas*.” I have found very decided specimens of the variety *ræticum* and *molle*, by the roadside between Cheadle Common and Great Yate. Here, also, is the *Ling*, the *Erica cinerea*, and *E. tetralix*, all springing from a bed composed of the most lovely Mosses conceivable, one of them being that beautiful and silvery kind which is such a pleasing contrast to the darker shades of the green varieties. I have thought as I strolled along amongst these humble children of nature, that they each preach their little sermon of love and kindness, which, if we will receive it, may enter into our hearts and bring forth as much fruit as a longer discourse from the eloquent lips of a human teacher. I have a favourite piece of poetry upon the mutual help which these lower orders of God’s creatures afford each other; it is so prettily told that I transcribe it for those who may not know it.

“There was Fern on the mountain, and Moss on the moor;  
The Ferns were the rich, and the Mosses the poor;  
And the glad breeze blew gaily—from Heaven it came—  
And the fragrance it shed over each was the same;  
And the warm sun shone brightly, and gilded the Fern,  
And smiled on the lowly-born Moss in its turn;  
And the cool dews of night on the mountain Fern fell,  
And they glistened upon the green Mosses as well.  
And the Fern loved the mountain, the Moss loved the moor,  
For the Ferns were the rich, and the Mosses the poor.  
But the keen blast blew bleakly, the sun waxed high—  
Oh! the Ferns they were broken, and withered, and dry,  
And the Moss on the moorland grew faded and pale;  
And the Fern and the Moss sbrunk alike from the gale.  
So the Fern on the mountain, the Moss on the moor,  
Were withered and black where they flourished before.  
Then the Fern and the Moss they grew wiser in grief,  
And each turned to the other for rest and relief;  
And they planned that wherever the Fern roots should grow,  
There surely the Moss must lie sparkling below.  
And the keen blast blew bleakly, the sun waxed fierce—  
But no winds and no sun to their cool roots could pierce.  
For the Fern threw her shadow the green Moss upon,  
Where the dew ever sparkled undried by the sun;  
When the graceful Fern trembled before the keen blast,  
The Moss guarded her roots till the storm wind had pass’d.  
So no longer the wind parch’d the roots of the one  
And the other was safe from the rays of the sun.  
And thus, and for ever, where’er the Ferns grow,  
There surely the Mosses lie sparkling below;  
And thus they both flourish where nought grew before,  
And both deck the mountain, the woodland, and moor.”

I remember taking one walk in November in the locality mentioned above, a small fine rain was falling, but my husband assured me I should be amply rewarded for my uncomfortable expedition, by a treat which he had in store for me. A *bas*, then, to grumbling! Do we not know, “There

is no catching trout without wetting one's trousers?" After plodding along for about a mile under the protecting care of our umbrellas, we turned down a short road. Upon stepping over the Moss and Heath by its side we found a tiny path close under the hedge; following it, there on the bank, peeping out from their leafy covert, were the most gorgeous orange and golden fungi! orange when in the earlier stages of development, and golden as the plant became more fully grown. Lower still on the ground were purple, brown, yellow, and white fungi of a smaller kind. Every spray was bent with fog and rain, to me it was a fairy place, with its pearly drops, dripping, dripping, slowly dripping, tenderly and refreshingly on these grateful tenants of the soft sward beneath them. I was most anxious to have preserved them, but was ignorant of any satisfactory method. Turning from this melancholy month to bright skies and warm weather, let us review this same roadside and the neighbouring moorland in the warm and pleasant months of June and July.

"Smiles the earth, and smile the waters,  
Smile the cloudless skies above us."

Let us be off again, basket in hand, with light footsteps, and happy faces to see what plants we can add to our hortus siccus. The results I must reserve for the next page of my notes.—ALICE.

### MESSRS. HENDERSON'S TULIP EXHIBITION

AT THE ROYAL HORTICULTURAL SOCIETY'S GARDENS,  
SOUTH KENSINGTON.

To the lovers and cultivators of spring flowers this exhibition will prove a rare treat. On Tuesday last the collection of Tulips was hastening to its prime; and if the weather has not proved too hot and promoted their decay, a visit to the gardens will gratify every person who will go and see them. There is a vast variety of shades of colour—brilliant, gay, and sombre. The colours have been arranged with good taste. The delicacy of the white flowers is exquisite. Now is the time for the amateur to make notes and take down names or numbers of these bulbs; but there must be no delay. The Tulips in the centre of the garden, which are the property of the Society, are very beautifully and tastefully arranged. They have the advantage over Messrs. Henderson's collection in their position among the green leaves, and have also had the benefit of more sunshine. The Society must feel much indebted to the firm which has so liberally supplied the barren ground of their garden with such a display; and it is greatly to be wished that this magnificent effect will encourage the amateur to cultivate this most brilliant and easily managed spring flower.—X.

### EMIGRATING TO NEW ZEALAND.

In your Journal some months since is a question from "J. C.," asking information respecting New Zealand, and whether it is a field for emigration.

1. He asks, Can Strawberry plants be sent out? I reply, Yes, they have been, and can be sent again.

2. Is it advisable to take tools? Decidedly yes, as he can get the best in England and select them himself, whereas in New Zealand you are obliged to put up with whatever there may be in the market. Especially he should bring his own spades, as most of those sent out are sent for sale and not for hard work. At the same time we are fast improving in the quality of tools of all kinds.

3. Does Quick thrive in New Zealand? Yes, exceedingly well; under proper management you have a hedge at four or five years old equal to seven or eight years in England.

4. Should a person bring his own seed out, and what sorts? A person never does wrong in bringing seeds of every kind of prime sorts except Beans, as there are plenty grown around Wellington.

5. Can settlers grow their own grass? Yes, there is a considerable quantity of Cocksfoot, Timothy Grass, and all sorts of Rye Grass saved every year. Clovers are imported from England. Any person coming out with the intention of farming in the country should bring with him the Poas and Fescues.

6. Is it a place for emigrating to? Any steady persevering man can get on, especially if he has a family of boys to assist him in his out-door work. Girls can obtain situations the moment they land. If he is a good gardener I think there will be plenty of employment now, as the seat of government is removed to Wellington, which will necessarily cause gardeners to be more in request.

Our fruit season has been very excellent this year for all kinds, especially stone fruit, and the weather has been very warm; but we have had an occasional shower in the night lately. I also send you experiments made by myself to see the influence of the moon on vegetation.

Sowed Sangster's No. 1 Pea. First row sown thirty hours before new moon. Second row sown four days after new moon. Third row sown, moon ten days old. Fourth row sown, moon eleven days old. Fifth row sown eight hours before the moon was at the full.

No. 1, five days coming up. Flowered on the 20th of November.

No. 2, four days coming up. Flowered on the 22nd.

No. 3 row, sown when the moon was ten days old, four days coming up. Flowered on the 29th and 30th.

No. 4 row, sown when the moon was eleven days old, four days coming up. Flowered on the 30th.

No. 5 row, sown when the moon was within eight hours of being full. Flowered on the 1st of November.

Gathered the first Peas, about equal from each row.

The first row was 57 days before gathering; the last row was 41 days.

I consider, therefore, that the best time for sowing is just before the moon is at the full; but I write under correction, and should be glad if some of your numerous experimentalists would give their opinion.

With this you will receive our usual summary; and you will perceive the noble race that the philo-Maori party in England so much eulogises have committed another brutal murder. They, the Maories, instead of nobility of soul, are cowardly, mean, and treacherous, and the means that have been used to preserve them will cause their entire destruction as a race. We old colonists are sorry for it. We have endeavoured to the utmost of our means to be friendly, but it is of no use.—VERONICA, Wellington, New Zealand.

### A WORD ON HOTBEDS.

EVERY one who has to do with hotbeds early in spring, experiences more or less difficulty in procuring a supply of fermenting material. Where early Cucumbers and Melons are required from the hotbed, to say nothing of the vast quantity of bedding and other plants needed for the floral display of summer, how often does one find the supply inadequate to the demand.

I will now briefly describe how I have managed with a very limited quantity of such material to propagate about three thousand plants since the 3rd of February. I wished for every particle of room afforded by a pair of two-light frames, each measuring 7 feet wide by 6 feet 3 inches long; but the greatest drawback was the dung being scarcely sufficient to form one bed in the ordinary way; but to make the most of what I had, and also to procure the desired space, I erected a stand for each frame. The stands were formed thus—four posts were let into the ground to the depth of about a foot and well firmed, the height of the posts above ground being 3 feet. These posts were fixed at each corner of the frame, and bearers were nailed at the back and front, and likewise along each side, for the frame to rest upon. The side bearers were flush with the frame, while those at back and front were allowed to go partially within the frame in order to form a resting-place for the soil-bearers, which consisted of a lot of old dry spruce fir tops. These were cut to the exact length of the frame, and laid in an inch apart, and on them some spray was laid crosswise; then a little pared turf grass side downwards, and finally the plunging material. It will be observed that there was no fermenting material under the frame, 2 feet 6 inches was left between each frame for the reception of dung, which when well shaken to pieces fermented freely and answered equally well for both. The rest of the frame received a lining 3 feet at the base tapering to 1 foot 6 inches at top. I contemplated

raising the dung to within 2 inches of the frame top, but was unable to do so for want of material. By obtaining droppings daily from the stable the desired height and heat were soon attained, and the heat of the bed has since been easily kept up by the incorporation of a few barrowloads of dung which accumulated in the course of twelve or fourteen days. The heat has been and is still very uniform, and answers admirably for Melons and Cucumbers. The stock of plants propagated since the 3rd of February consisted of variegated Geraniums of various kinds, Chrysanthemums, Fuchsias, Verbenas, Lobelias, Dablias, Gazanias, Ageratums, Heliotropes, Variegated Alyssum, Begonias of varieties, Gnaphalium lanatum, Centaurea of sorts, &c. The last of the whole batch was potted off on the 1st of April. The plunging material having been removed from the frames, was replaced with some appropriate for the culture of Cucumbers and Melons, which are now the sole occupants. These few notes may be of service to some of your amateur readers, although the system is by no means novel, for seven or eight years ago I saw it adopted with good results at a small place in Surrey.—JAS. BECKETT, *Cowdenknowes, N.B.*

#### EXTRACTS FROM SIR W. J. HOOKER'S REPORT ON THE ROYAL GARDENS AT KEW DURING 1864.

THE number of visitors to the Royal Gardens during the past year presents an increase of 72,245 over that of 1863; and was distributed as follows:—

Total number on Sundays .....	218,308
Total number on week days .....	254,999

#### BOTANIC GARDENS.

The most important change which I have to mention in this department, and indeed in many respects the most important that has occurred since 1841, when I was appointed Director, has been the retirement (owing to an affection of the eyes), of our able and highly valued Curator, Mr. John Smith, who, for upwards of forty years has superintended all departments of the Royal Gardens, and whose services and fidelity have been recognised by the Treasury in granting him the highest scale of pension. Indeed, previous to my taking office, Mr. Smith's services to the Gardens and to science were mentioned with approbation by the Commissioners, whose report on the condition of the Royal Gardens was presented to Parliament in 1833; and they especially drew attention to the fact, that to Mr. Smith alone (then a foreman) was due the credit of having named any of the plants, whether for the interest of science or the instruction of the public.

As may well be supposed, it has been found impossible to obtain another curator who combines with the necessary amount of skill as a cultivator, and efficiency as a general manager, that knowledge of rare, curious, and useful plants which our late Curator so eminently possessed. But his successor (also Mr. John Smith), late head gardener to his Grace the Duke of Northumberland at Syon House, not only bears the highest testimonials for skill and ability as a horticulturist and as a general manager, but has further long been known to myself and other botanists as having that special fondness for the cultivation of tropical and economic plants, for which the Syon gardens have long been celebrated throughout Europe.

I have only to add that Mr. Smith, who entered upon his office on the 16th of May, has proved himself eminently qualified for the curatorship, and is rapidly acquiring that special knowledge for which his predecessor was distinguished, and which experience alone can bring.

About 4000 live plants and 4600 packets of seeds have been distributed.

Steps are being taken to introduce the *Ipecacuanha* into Ceylon and India. Young plants have been received from Mr. C. H. Williams, of Bahia, and are being propagated for transmission.

The Cork Oaks, mentioned in my last report as having been sent out at the request of the Government of South Australia, have arrived in excellent condition, and are thriving. Under the direction of George Macleay, Esq., similar cases of live Cork Oaks have been sent to Victoria, Sydney, and Queensland; of these the second alone has

failed, and other cases are now preparing to be sent there; those sent to Victoria and Queensland have arrived in good condition.

Most flourishing accounts of the *Cinchona* plantations continue to arrive from India.

In the Nilgherries, Sir Wm. Denison informs us, that though the country had in April last suffered from 112 days' drought, yet the *Cinchona* plantations had not been damaged; and that the plants were being propagated at the rate of 30,000 to 40,000 monthly. From Ceylon Mr. Thwaites writes that in September last he had 190,000 plants, the tallest 6 feet high;—that applications had been received for 28,500 plants, of which 9000 had been supplied; and that he expected to issue 20,000 monthly.

#### HERBARIUM AND LIBRARY.

The scientific duties of the Royal Gardens continue to be the most onerous connected with the establishment; owing to the incessant demands for the names of plants in our own and other gardens, and of those collected by travellers and explorers on Government and other expeditions; and for information as to economic plants and vegetable products; in addition to the extensive and ever-increasing colonial and foreign correspondence and publications.

The principal works done in this department, or in connection with it, have been,—

1. The publication of the second volume of the Flora of the Australian colonies, by G. Bentham, Esq., assisted by Dr. Mueller, of Victoria, who continues to send his own Herbarium for examination, and all the newly discovered plants as they are received by him, with notes and observations, for this work. The third volume is in progress; published under the authority of the several Australian Governments.

2. The Flora of the Cape Colony, British Caffraria, and Natal, by Dr. Harvey, F.R.S., of Dublin, and Mr. Sonder, of Hamburg. The third volume of this will shortly appear, published under the authority of the Cape Government.

3. Dr. Grisebach's West Indian Flora is completed in one thick volume, and was published under the authority of the Secretary of State for the Colonies.

4. Mr. Thwaites' Enumeration of Ceylon plants is completed and published.

5. The first volume of a Handbook of the New Zealand Flora, prepared by Dr. Hooker at the desire of the Government of that colony, is now published; and the second volume is in course of preparation.

6. The ninetieth annual volume of the "Botanical Magazine," being the twenty-fourth prepared at Kew, has been published by the Director, with seventy-two coloured plates of new and rare plants that have flowered in the Royal and other British gardens.

Of other works in preparation the most important are:—

7. The Flora of British India, by Dr. Thomson, F.R.S., under the auspices of the Secretary of State for India.

8. The outlines of the Flora of tropical Africa, by Professor Oliver and Dr. Hooker.

9. Dr. Mueller, of Geneva, has spent three months at Kew, for the purpose of describing the Euphorbiaceæ for M. de Candolle's Prodrômus.

10. M. C. de Candolle, of Geneva, has described the natural order of Peppers for the same work.

11. Mr. Lowne has named and arranged his large Palestine and Lebanon collections, made during the Rev. Mr. Tristram's expedition.

12. Dr. Kirk has rendered us great service in arranging and naming his own and other East African collections, and the Mauritius ones of the late Dr. Ayres, Judge Blackburn, and others.

13. Mr. Spruce is residing at Kew for the purpose of arranging his Andean, &c., collections.

14. Dr. Triana of Bogota was for several months engaged on his Flora of New Grenada, published for the Government of that Republic.

15. The Japanese and Korean collections of Mr. Oldham, amounting to about 13,000 specimens, have been named and distributed to various public museums.

16. The distribution of the great Herbarium of the East Indian Company has been proceeded with; and that of the Kashmir, Punjab, and Himalayan collections of Dr. Falconer commenced.

The principal contributions to the Herbarium and Library have been:—

1. The collection of specimens, drawings, and MSS. of Carices, of the late Dr. Francis Boott, F.L.S., formerly Treasurer of the Linnaean Society; presented by his widow. It is impossible to over-estimate the value of this gift. Dr. Boott devoted the greater part of his life to the study of this particular and very difficult tribe of plants; he formed a complete and beautifully arranged and named collection of the species from all parts of the world; and was for thirty years the standard authority for their nomenclature. At his own expense he caused to be prepared in Paris and London a superb series of folio drawings of all the species, of which upwards of 400 were published, with descriptions, in three volumes, and privately distributed, also at his own expense. The entire number of drawings amounts to upwards of 700.

2. The Herbarium and MSS. of the late Dr. P. B. Ayres, colonial surgeon of Mauritius; presented by his widow. Dr. Ayres spent upwards of ten years in the Mauritius, during which time the whole of his leisure was employed in exploring its botany, and describing the plants for a Flora which he intended to publish. This Herbarium, which is a very considerable one, together with the MSS., will prove of great use in the event of a Flora of Mauritius being published, which is in contemplation by the Colonial Government.

### BARREN STRAWBERRY PLANTS.

At page 804 your correspondent "W. B." has thrown out some hints on barren Strawberry plants, and it may not be out of place here to mention what has come under my own notice.

A friend has a large garden, and some years since, when I was taking a walk with him in the garden and chatting on bee matters, my attention was also drawn to the fruit, which promised to be abundant. "But what is the reason you have no Strawberries?" These were at the time growing to the south of some Arbor Vitæ trees. "Oh," replied my friend, "these are some plants which my nephew sent to me five years ago." "Then they are too old; they ought to be transplanted." "But," said my friend, "there never was either fruit or blossom on them; they are male plants." "Oh dear!" rejoined I, "that is wrong. Transplant them, and you will see them grow into females." He did transplant them, and in two years afterwards he had the most abundant crop I have ever seen.—A LANARKSHIRE BEE-KEEPER.

### FLOWER-GARDEN PLANS.

You have taken me rather at a disadvantage by publishing the remarks which I sent you upon flower-garden plans (which were elicited by your adverse criticism on borders in front of houses), as they were hastily written and I intended to write you a paper on the subject.

I did not wish to make any invidious remarks between "E. A. L.'s" design and the one from Houndstone House, Yeovil; but merely alluded to them as they happened to illustrate my ideas on the subject. I have, I am afraid, misled you to suppose that the design by "E. A. L." was one of my own, as I said I originally laid out the garden, and recommended that the border in front of the house should remain. Since then, however, all the ground in front of the house has been levelled into two terraces, the upper one for King Croquet and the Lords and Ladies of the Hoops, &c.; the other has been occupied by the design in page 214, of your Journal, which is "E. A. L.'s" own. When I originally laid out the garden, I had to cut out beds adapted to the uneven surface of the ground, and they were rightly done away with when the ground was levelled. I may, therefore, without prejudice, defend "E. A. L.'s" design, which is one particularly well adapted for the piece of ground it occupies, which is level with an irregular outline.

And now I would add a few remarks upon the rules which I laid down for flower-garden plans, and also upon your criticisms.

First. Every bed ought to make a perfect and uniform shape. By this I mean, that if it is divided by a line down

its centre, one half ought to be equal to the other half; circles, squares, ovals, quatrefoils, trefoils, &c., follow this rule, as do nearly all geometrical figures. This is easily illustrated by architectural details, as windows, arches, stall ends, &c. When I use the word perfect, I do not mean to say that there are not other shapes more perfect or more beautiful, but that it does not require anything added to it to make it uniform. It is, therefore, perfect, of itself. A circle is perfect in itself, and is, perhaps, for bedding-out plants the best possible shape, but it is not beautiful, at least as far as the mere outline is concerned. The circle is not a beautiful figure in architecture, but a circular window filled with tracery and painted glass is, perhaps, one of the most strikingly beautiful features in many buildings—for instance the circular windows in York Minster. I adduce these as an example, because a circular bed, which is a very simple form and not beautiful in itself, is often made most beautiful by its setting with bedding plants, aided by other beds or the set of beds, of which it may be the centre.

2. Walks ought to form patterns as well as the beds. No doubt, as you remark, the walks will always form patterns, but very often the patterns of the walks are sacrificed to the beds, the beds being cut out with very little reference to the shape of the walks, merely leaving an irregular space, haphazard, after the beds are cut out. The walks are generally intended, I presume, to enable persons to walk amongst the flowers, to enjoy their beauty, and examine them closely, or to allow the gardener to work amongst the flowers without treading on the beds. Now, in many plans I have seen the grass left so narrow in places between scroll-beds, that no lady could walk between the beds to pick a flower without brushing the beds behind, and even a gardener at bedding-out time would find his feet in the bed behind him if he knelt down to plant. I say, then, that walks ought, as far as possible, to be of a uniform useful width, one which will admit a barrow or a mowing-machine, and they should not be merely spaces left at random. A flowing artistic outline may sound well theoretically, but practically it does not work so well, unless it is in Box and coloured gravels for winter gardens. Patterns, that would look well for ladies' embroidery, would not leave suitable spaces for ladies' crinolines, and we do not wish to banish the fair sex from our gardens.

3. All pointed or unequal-shaped beds ought to be avoided. I own that "E. A. L.'s" beds have a good many points, but none of them present any difficulty in planting, as the engraver by diminishing the size of the beds, 2, 2, &c., has made all the points in the set, 2, 3, &c., much more acute than they really are. I do not think any angle over 60° a sharp point, especially if not too much prolonged. Now, in the plan, page 232, the points, 6, 6, and the ends of the scroll, 4 and 3, are prolonged points—that is to say, if the bed was 2 feet wide 6 feet from the end, it would be gradually diminishing from these to the point. Now, suppose you tried to plant 4 with *Calceolaria* and edge with Purple King, the edging would run to a narrow single line. In fact, with the proposed planting of *Calceolaria Aurea floribunda*, the plants would soon overgrow the points, or else the last foot of the points would have to be left plain soil. No set of beds can well be made without angles, but the less the angles run into prolonged points the better.

Rule 4 requires no explanation, as I have already referred to it, and I think you quite agree with me as to the truth of it. I alluded to the division of animals through the vertebrae, and leaves through the midrib to illustrate what I meant by a uniform bed, not by a set of beds. I quite agree in preferring that a set of beds should be capable of being divided into four equal parts by lines drawn at right angles through the centre point. It does not necessarily follow, however, that these lines should be on the walks, otherwise the walks must be nearly always cruciform; but if they fall upon beds they must divide them equally. The plan at page 214 follows this rule, and two lines through the centre of the quatrefoil 1, at right angles through 2, 13, 14, &c., will divide it into four equal parts. I quite agree, however, that the quatrefoils 16, and circles 12, 13, 13, and the bands round are not necessary as far as making a perfect figure, and think that your rule, that in a set of beds, no clump ought to be capable of removal and another substituted in its place without injury to the set, is a perfectly

true one. It so happens, however, that in "E. A. L.'s" plan it was desirable to lengthen the bed more one way than the other, owing to the space on which it had to be cut. The bands, consequently, were run round the two circles, 13, 13, and not round 12, 12.

The plan I have given is purely geometrical, and is adapted to fill any space where there are no very definite outlines, although, of course, it would fill a square or a circular piece of ground very well. It will also answer either as a centre or outside in a set of three beds to fill a long terrace. Three distinct sets of beds, the two outside ones being similar or nearly similar, very often fill a long terrace garden or parallelogram better than one continuous figure. My remarks may seem chiefly to apply to geometrical gardens on grass. I admit that with Box and gravel greater irregularity is admissible; but, still even with scroll-beds, I think that one half ought to be made to balance the other as nearly as possible, and no scroll-bed ought to be made so large as to require planting in different divisions.

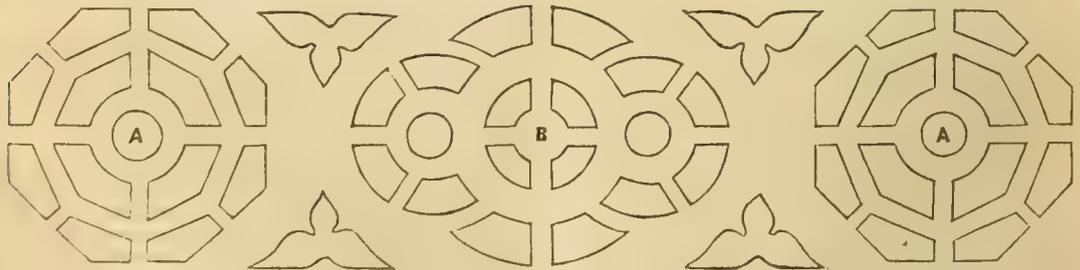

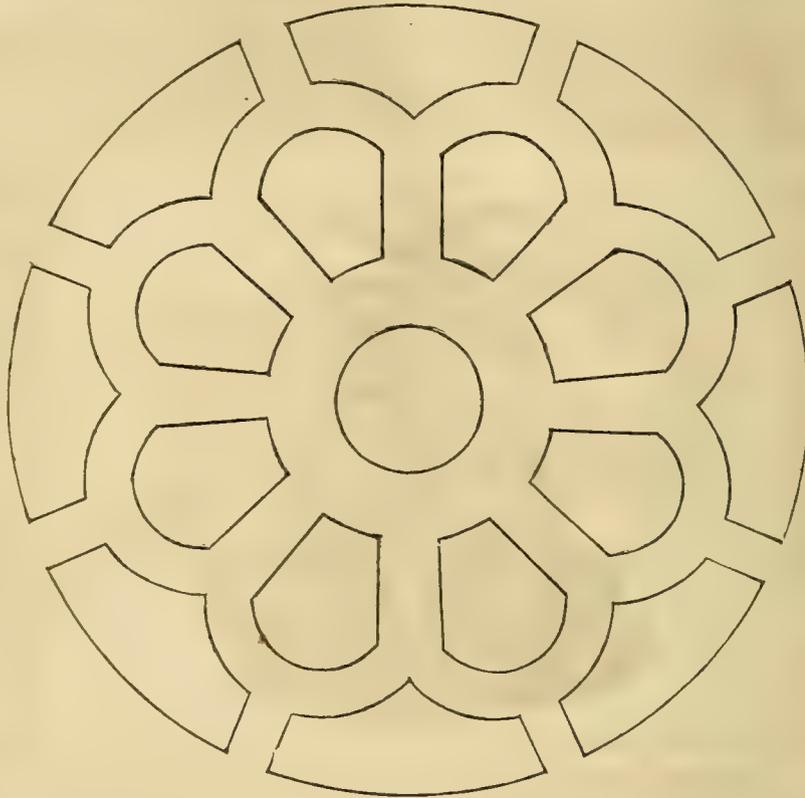

Of course, to the end of time there will be "*quot homines, tot sententiae.*"

I do not think, however, we differ very much on the whole, unless it is with the exception, that I am still an advocate for creepers against a house, except in cases of large mansions or houses with a good deal of architectural

border looking untidy, or desolate, in the winter. I think few lovers of Roses would like to be without them on the walls of their houses. Of course, my remarks do not apply to large mansions with gravelled terraces, balustrades, &c., in front, but to nine-tenths of the ordinary run of country houses. In fact, I only know of one or two near here, one of which is Castle Howard, the seat of Lord Carlisle, that would not be better of a few creepers, as Roses, &c. I am not an advocate for smothering a house with Ivy and other rambling creepers, but to have a few choice creepers and keep them distinct, as Roses, Wistaria, and Trumpet Honeysuckle, &c. — X. Y. Z.

P.S. Since writing the above, I have found a tracing of a garden which I designed and cut out last year, and I send it instead of making any new design, as it exemplifies what I have said with respect to three sets of beds forming a good plan for a long level terrace. This plan was cut out on a terrace about 45 feet broad facing the house, a broad gravel walk lies between the house and the terrace, which is sunk about 2 feet below the walk, and slopes very slightly

from one end to the other, the fall being about 1 in 100. The walls of the house are trellised, and there is a border in front, the trellis and border being continued beyond the house parallel to and up to the end of the terrace. Beyond

A A, Raised Beds.

B, Ornamental Vase.

beauty. My own is a new house, and I flatter myself not unsightly, but when there were two or three hundred blooms of Général Jacqueminot all out at once on plants which I have trained up the house, it was more adorned than by the best architectural features. When bedding plants are used in the borders where the creepers grow, other plants can, without very much trouble, be made to supply their place during the winter and spring months. Variegated Arabis is a permanent edging that looks well nearly all winter, and a few bulbs and spring flowers, and small plants of variegated evergreens—as Hollies or Box interspersed, will prevent the

terrace to the south, at a lower level, is another terrace for croquet, surrounded by a few standard Roses in small round beds which carry on the eye from the garden above. I will not trespass on your space by any further explanation, but send the plan as it is.

[We quite agree in most of what you advance. As to the plans, we have no doubt the round group will look well when planted. In our opinion the circle is not only the simplest but the most beautiful of figures; the eye never tires in looking round it, and there are no jutting corners.

Of the long terrace group we much prefer the central figure or group. There will always be many opinions on such matters. It is always a pleasure to see such matters not only ably, but temperately stated. Perhaps like heterodoxy

and orthodoxy, we are all rather prone to make our own "doxy," orthodoxy, and other peoples "doxies," heterodoxy. We have striven against this failing in our Journal, and we are glad to be so ably assisted by you.]

PALMS AS ROOM PLANTS.

DURING our recent journey to and from the International Congress of Botanists and Gardeners at Amsterdam we visited some of the widely-famed nurseries of Belgium. On a future occasion we shall place before our readers some general notes upon those establishments, but now we ask for special attention to only one subject they forced upon our notice.

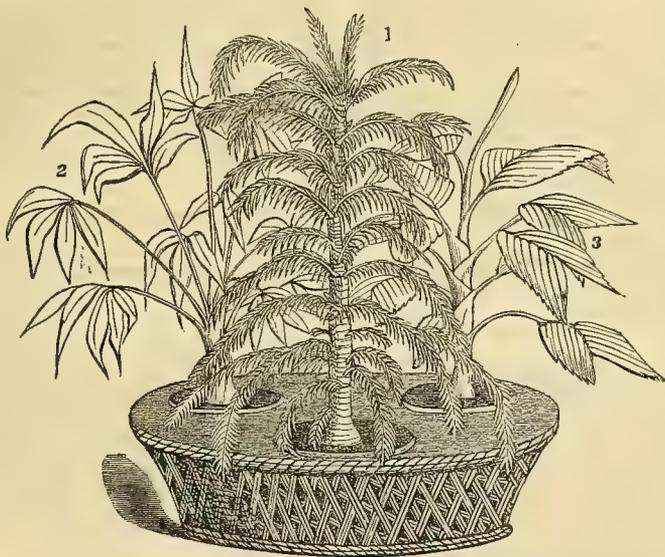

We marvelled to see the very great numbers of dwarf Palms in pots that were in the stoves and greenhouses of those nurseries. They were not large specimen plants, such as we see at Kew and elsewhere, but varying in height from a few inches to 2 or 3 feet. The pots they were in were not more than 6 or 8 inches in diameter; and to keep up the supply we saw numerous pots with the Palm seeds, as usual, merely placed on the surface of the soil, and germinating in those fantastic forms which so characterise them.

Upon inquiring we ascertained that this large supply of Palms was required for the in-door decoration of the residences of the Russian and German gentry. The demand for such purposes may be appreciated by the fact, that of one species alone, *Thrinax elegans*, Mr. Verschaffelt, of Ghent, has sold 20,000 during the last ten years, being an average of 2000 annually.

He assured us that they are the most manageable of room-plants. They are infested by no insect; the well-known dryness of a dwelling-room's atmosphere, so injurious to most plants, has no perceptible effect upon the young Palms. Then their leaves are of such a form and so firm of texture that the dust may be removed from them with a damp sponge, readily and without fear of injuring them. Neither is their price an obstacle, for when of a full growth for room-decoration they cost only about 4s. 6d. of English money. The usual temperature of our sitting-rooms is sufficiently high for their healthy growth; and their growth is slow, so that years elapse before they have to be removed to be replaced by more juvenile successors.

The following is a list of some of those species found to be most suitable for room-decoration, and we are quite convinced that if our nurserymen will obtain these Palms from the nurseries of either Mr. Van Houtte or Mr. Verschaffelt, and maintain a supply, it

would soon become an extensive branch of their business:—*Chamærops stauracantha*, *Ceroxylon andicola*, *Thrinax elegans*, *Phoenicophorum sechellarum*, *Chamædorea Ernesti-Augusti*, several species of *Pandanus*

1, *Ceroxylon andicola*. 2, *Chamærops stauracantha*. 3, *Chamædorea Ernesti-Augusti*.

THE NEW JAPANESE EVERGREENS.

As the introduction of new and untried plants that eventually will become universal favourites is often difficult, from the uncertainty whether or no they are hardy in this climate, the experience of every amateur who has tried them and who has taken a fancy to them may be worth inserting in "our Journal." First and foremost come the *Aucubas*, with their many variations of blotchings. Some years ago one was sent out with large uncertain blotches on each side of the midrib, but it did not take the fancy of purchasers, for it was not nearly so effective as the old spotted kind. Now, indeed, there is more choice to please all fancies, for whether you select the *picturata*, with its centre golden, or *limbata*, with its edges golden, or the *himalaica* with its large, deep green, glossy leaves—all are handsome. We country amateurs, with small gardens and small means, for a long time can know new plants only by the catalogues and by stray chances of rushing to Henderson's or to Veitch's or other leading nurseries, and so are often puzzled how to distinguish plants very much alike in name, habit, and description. How, for instance, will you distinguish *Aucuba himalaica* from *japonica*? I knew the difference of habit and of growth, but which was which I could not tell. On visiting Garaway's nursery at Bristol the intelligent foreman showed me, and I will now retail his information. The *japonica* exactly resembles in its growth the

well-known spotted kind; when in bloom the petals are purple, and the spike very short—in fact, compare it with the old sort in bloom and the resemblance is complete. The berries are close-set on the branch and are oval. The *himalaica* is of freer growth; the leaves not so flat and more pointed; the blossoms are on a longer spike, and the petals are white or pinkish white, and the berries are round. Garaways hope to keep a plant of *japonica* in fruit till the June show, and if it do not charm the Bristol people I shall be surprised; its growth and condition were so perfect I would have walked six miles with pleasure to see it. The difference of growth and flower is that of *Quercus robur* and *pedunculata*. The plants sent out as *picturata* having turned out to be male, to the surprise of the purchasers, have enabled very many more plants to be fruited than otherwise would have been the case, and, doubtless, in time we shall from this source obtain new varieties of colour.

Having bought both the *himalaica* and *japonica* for the Bath Park I can testify that both are hardy; neither have had more shelter than being planted on the south side of a wall; the leaves of the *himalaica* were shrivelled and brown from the snow and frost, whereas *japonica* was quite unaffected by the winter weather.

How can the catalogues promise that these plants shall produce berries unless they supply at the same time a male

plant and instruct purchasers how to manage matters? Neither are monocious. By-and-by, when males are more common, it will be as well to have a spray of the male grafted in the middle of a bush of the female plant, should this be within sight of a house. I have lent out to a nurseryman my male to fructify his young females, but hope to have a stray bloom or two left for my own home plants that are just opening.

The *Elaeagnus variegatus* will be a beautiful addition to our lawns. The growth of the reflexus is very peculiar. Here it has grown most freely, the shoots of last year were 6 or 8 feet long, and the frost did not hurt it the least. If they had been white instead of the peculiar dark brown, the effect would have been most pleasing; but it is always to be remembered that variegation is but disease, and brings with it the penalty of greater tenderness of constitution.

The *Euonymus ovatus aureus* has also proved perfectly hardy here, not influenced by the weather. Its branches being so brightly golden render it more marked in character than the old white variety.

*Euonymus radicans variegatus* becomes very charmingly tinted with red after much cold weather. It is as though every leaf had been shaded with a thin layer of lake. It is very hardy.

*Eurya latifolia variegata* I cannot speak of. I saw it in Veitch's collection, and much admired it, but the foreman was doubtful about its hardiness. The old *Eurya japonica* is perfectly hardy here.

*Osmanthus ilicifolius* in its varieties is also quite hardy. I had not seen the aureus till last week, and the shading of the leaves is very pretty, not margined as in the white. What are to be the blossoms? What the natural family? It looks so like a Holly.

The Umbrella Pine (*Sciadopitys*), *Retinospora pisifera*, and *Thuopsis*, all recently introduced from Japan, have all gone through the past winter without protection uninjured; but this tribe does not flourish in our valley so well as in drier climates, and more porous soil, so I have not interested myself in them so much.

The large-leaved Berberry (*Berberis Fortunei*) will prove a beautiful addition to the shrubbery. Its leaves are brilliantly tinged with red in the winter. While talking of shrubberies I would ask every one to see, and he will admire, *Forsythia suspensa*. This spring this shrub is most splendid. It far surpasses the old *F. viridissima*.

Like many other superficial folk I have written too much upon a subject of which I know but little, and have not referred to the variegated Ivies and the Honeysuckles, also introduced by Mr. Fortune into our gardens. The tender tribes needing protection are beyond my province. My object is only to elicit further information from experienced pens.—B. J. S.

## RAISING NEW VARIETIES OF FRUITS AND FLOWERS.

THERE is no class of men more worthy of respect than the really intelligent gardeners of this country, and considering the knowledge, patience, industry, and forethought required to make a good gardener, they cannot be considered a well remunerated body. I am not speaking of the conceited ignoramus who in his own estimation knows everything, but is far too knowing to let you into his secrets, or the pedantic who talk of Latin and science, but cannot show you a bunch of Grapes fit to put on a gentleman's table, who think growing a Peach or Apricot in a pot an impossibility, and themselves wonderful men, because by planting thousands of *Verbenas*, *Geraniums*, &c., they can produce a blaze of colour for a few weeks in the autumn. I would address myself to the really intelligent gardeners, and say I know some of you think that in the present day you are not paid in proportion to what is expected of you. Many of your class have turned nurserymen and florists to try and better their condition; some have succeeded, and many more have miserably failed. How is it so few of your body try to raise seedling fruits and flowers, or of the small numbers who do raise a good thing, how is it so few reap the advantage?

I wish to call your attention to the subject. No master,

I think, would object to see a dozen seedling Vines in his houses, a batch of seedling *Geraniums* on a spare shelf, or a few seedling fruit trees in a corner of his garden. Such a pursuit would keep up the interest and hope of a clever man.

But, some will say, What if we did raise a good thing, how are we to make money of it? Not, I would say, by giving a cutting to a friend or two, on condition of their keeping it to themselves, or selling the stock to the first man who offers you a £5 note for it. Few of our best gardeners have any idea of the value of a really good seedling of any popular fruit or flower.

My advice would be, Choose a respectable nurseryman, give him the plant, and get an agreement in writing that he should propagate and sell, taking all the trouble, and keeping an accurate account of all sales, and that in most cases you ought to equally divide the amount received. It is astonishing how many good things have got out without any one being much the better for their having been raised. Nor would the gardeners only be benefited by the plan proposed. It would be equally beneficial to masters, because it would tend to secure the services of superior men. Some one has said, that "virtue withers unless watered with rewards."—J. R. PEARSON, *Chilwell, Notts.*

## PRESERVING DAHLIA TUBERS.

As I hear that during the last severe winter many persons have lost most of their Dahlia tubers, I think a few remarks upon my own experience may be useful. I have for some years endeavoured to find out the best plan for keeping these tubers. I have tried Apple-rooms, lofts, and all sorts of coverings to protect them from the frost, damp, and too rapid growth, but have always lost many of them. Last autumn I placed them on the ground in a Potato shed, and buried them in ashes, and although we have had a most severe winter, I have not lost more than one in fifty. The ashes of our Welsh culm, which are composed of burnt coal and clay, may be superior to other ashes. They have certainly answered the purpose well with me.—A SUBSCRIBER OF SOME YEARS, *Cardiganshire, South Wales.*

## THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

I NOT only wish to draw the attention of all gardeners to the great claim the Gardeners' Royal Benevolent Institution has upon them, but also to enlist the sympathies of all connected with horticultural pursuits for its assistance. I do so confident of its great usefulness, judging from the past, forming, however, but a small fraction of what this institution would be capable of effecting did it but receive that support from those for whose benefit it was originally established which might be expected from them. Why gardeners are so very lukewarm with reference to the institution I am at a perfect loss to know—why so wanting in that sympathy as a whole. At a very moderate computation there are at least eight thousand gardeners who have each the ability to support this excellent institution, and yet what is the fact? Of these and many more the number entered as subscribers is a little over three hundred! The pensioners, almost wholly gardeners and widows of gardeners, are as one to every six subscribers of the same class and calling. The subscriptions are but 21s. per annum to constitute a member, no other expense whatever being necessary for entry, &c. Truly a trifle, yet what comforts it is capable of securing!

Now, as to the good this Society has already done since it was first instituted in 1838, I will quote the statement of the Secretary, Mr. Cutler. He says:—"In reply to your inquiries, this institution first commenced granting pensions in the year 1840. The number of pensioners who have been pensioned since that time is 134; and the amount which has been paid away in pensions from January, 1840, to Christmas, 1864, is no less than £11,745 13s. 8d. The amount paid in 1840 was £9 6s. 8d., and the amount paid in 1864 was £773. This will give an average payment for the twenty-five years of about £468 4s. 8d., and an average

payment per pensioner of £80 3s. 10½d. The amount of the funded stock is £5700."

No comment on this statement is necessary. Of the above funded stock, £200 was laid out last year in consols. At the present time it is advertised to add three more pensioners to the list, already containing twenty-seven men and twenty-eight women, many of whom are entered direct upon the death of their husbands. As to the pensioners, I can speak from personal observation of the good this outlay does. How cheerful it makes the last days of many, who daily thank Providence for first influencing them to add their mite to the yearly subscription of the Gardeners' Royal Benevolent Institution, in no expectation then that the adverse winds of life would have compelled them to seek its shelter! With the administration of the institution I think none will find fault; whilst the result of every election is the return of the most needy, the widow at all times having an overwhelming majority, and the spirit which prevails amongst the subscribers is of the best.

In conclusion, I earnestly desire my fellow gardeners to give a few moments' serious thought to the claims which this institution has upon them, confident of its merits and the good of which it is capable.—W. EARLEY, *Digswell*.

### GUTTERED FLOWER-POTS.

I BEG leave to state that upwards of twenty years ago I invented my plant-protecting flower-pot, which I gave to the public, unfettered by patent.

My flower-pot was figured in "Johnson's Gardeners' Almanack" many years ago; but as it was figured without my knowledge its utility was only partly discussed. My flower-pot has a double rim forming a gutter, which is filled with water, protecting the plants from creeping insects. I also use the pots for forcing Sea-kale with great success. I use for a cover a flower-pot of the same form as the other pot, but single-rimmed and without a drain-hole. When this cover is on, the edge rests in the gutter, which is full of water, and so prevents the air and vermin from getting to the plants, and accelerates their growth.—JAMES STEPHENS, 9, *Plum Street, Havelock Place, Sheffield*.

### STRAWBERRY PLANTS TREATED AS ANNUALS.

I GROW all my Strawberries as annuals, and of all the early varieties have no difficulty in securing a tolerably abundant crop. May Queen and Black Prince were finally discarded last year, and, with great regret, I fear I shall have to add the beautiful and prolific Princess Frederick William to the number of the expelled. All three are with us so utterly destitute of flavour and sweetness, that I now rely upon Marquise de la Tour Maubourg, as the first Strawberry worthy of a place upon our breakfast-table. It is remarkably prolific and vigorous in growth, but somewhat deficient in size. Prince Imperial, after the same strain, is a marked improvement upon it both in size and flavour, and ripening as it does only a day or two days after Marquise, I shall feel obliged by your suggestions as to combating a serious drawback to its treatment as an annual, at least as grown here.

Of my plants this spring fully one-third show no signs of blossom, whether under glass or in the open ground, and, somewhat remarkably, on examining the barren plants I find that, without exception, every one of them shows two buds, the fertile plants as invariably showing only one. Now, does there occur a period in the life of the plant when it elects, as it were, whether to form one blossom-bud or two? Prince Imperial with us has evidently in the past season tried to make many duplicates, but either failing in the attempt altogether, or not perfecting the work, the results are two leaf-buds only. By what treatment can I secure either that each plant shall have its own bud, or, if more, that the increase of buds be in the direction of blossom rather than leaf?—FRUIT-EATER.

[Properly speaking, an annual is a plant, the seeds of which being sown, passes through all its stages of growth, fructification, and decay in the same season. We have our-

selves never fruited Strawberries as annuals except the Alpines, which often bear very freely in the autumn from seeds, sown in spring. The nearest approach to annual culture is, the taking the runners of this season and fruiting them the next. This is the general plan followed in the south for forcing Strawberries, and if the runners receive an equal amount of attention, they will fruit as well if not better out of doors. Unless in very light soils, however, we do not see much advantage in this practice out of doors, as invariably in loamy soils, even under the above circumstances, the second season's crop is generally better than the first. As to Prince Imperial not fruiting as you wish in-doors, or out of doors, but many showing no bloom, we can add little to what was stated lately in "Doings of the Last Week." If we had plenty to choose from, we would take no runners from these barren plants. We have long ago noticed, that plants which divide their crowns are more apt to be barren than those having only one stout bud or crown. The whole matter is somewhat mysterious, especially if all the plants, barren and fruitful, came from fruitful plants. We should not like to advance more than a supposition as to the cause of these double and triple crowns; but our present conviction is, that they generally occur from over-feeding and too much pot-room, which prevent the bud ripening, and thence the luxuriant growth. We have often gathered out of 4½-inch pots double the weight that some friends have obtained from plants in pots of double that size. It is impossible to give such plants too much light in the previous autumn, but it is very possible to make them too luxuriant. What say other correspondents?]

### GARDEN PESTS.

ONE of the most destructive insects which infest the garden at this season of the year is the *Haltica nemorum*, commonly called the black flea or black fly, which is a small beetle-like insect, and most remarkable both for its agility and good scent, as thousands will jump to the ground in an instant just before you approach them. Broccoli, Kale, Brussels Sprouts, &c., have been literally covered with them. The destruction, however, which they have made on Peach, Nectarine, Pear, Cherry, and Plum trees is the most serious, as many trees of the first two at this place have been deprived of nearly every blossom. We have tried soot-water, lime-water, and tobacco to make the leaves, &c., distasteful, none of which, however, appear to drive them away. A good rain with cooler weather is, perhaps, the only thing to put a stop to their depredations. If any of your correspondents can recommend a method by which these troublesome pests can be either destroyed or driven away he will oblige myself and many others.—JOHN PERKINS, *Thornham Hall, Suffolk*.

### ENTOMOLOGICAL SOCIETY'S MEETING.

THE April meeting of the Entomological Society was held under the presidency of F. P. Pascoe, Esq., F.L.S., when donations to the library from the Royal Agricultural Society, the Linnean Society, &c., were announced, as well as M. Doleschall's Memoirs on the Diptera and Spiders of the Indian Archipelago.

The President exhibited an apparently new species of the Lamellicorn genus *Bolboceras* taken by Mr. Odewahn at Gwalor near Adelaide, South Australia, where it is found burrowing in the hard roads near that place, and coming forth only at night. The President had observed a similarity of habit in the European species *B. gallicus*, which burrows in the sand in the south of France. Mr. De Boulay had also observed these insects in Western Australia, and that they make a noise by rubbing, as he states, the pulvilli against the coxæ. The President also read a notice which had recently appeared in the "Athenæum" relative to the Rose-like Galls found on Willows in Cambridgeshire, exhibited at a previous meeting by Mr. Bond, and which according to the writer seemed to afford an explanation of the medieval miracle of Willows blossoming like the Rose at Christmas.

Mr. F. Moore exhibited a small collection of Lepidoptera taken in the North-western Himalayas by Capt. Lang, in-

cluding a new species of *Chrysophanus* (one of the Copper Butterflies), a *Pieris* like *Cardaminis*, &c.; also two curious species of Moths (*Noctua* and *Geometra* sp.), the bodies and wings of which were covered with slender elongated fungi, which had sprouted out all over them. They had been found at Darjeeling by Mr. A. E. Russell. A large collection of Beetles, Butterflies, and Moths taken by the last-named gentleman in Bengal and the Himalayas was also exhibited by Mr. Inanson, amongst which were two new species of the singular genus *Epicopeia*.

Mr. W. W. Saunders exhibited six or seven different species of Galls collected by Mr. B. T. Lowne in Southern Syria in 1864. One of these upon a species of *Atriplex* was covered with a woolly-like growth; another upon a blade of grass was probably the production of a Dipterous insect; another, of a solid texture, on a *Tamarix* was possibly the nidus of a *Buprestis*; another, upon a *Beaumuria*, contained a mass of about thirty eggs of some species of Moth.

The President read a note respecting certain insects which he had noticed in July last when passing over the snow field of Monte Moro at an elevation of 8000 feet. Here and there in the snow was seen a sharply defined cylindrical hole, about an inch in depth, and at the bottom of each was either a small lump of matter resembling peat, or more frequently a Dipterous or Ichneumonideous insect. He conceived that the insects, settling on the snow, became torpid from its low temperature, and then gradually, or perhaps rapidly, sank into the snow, the holes being caused by the radiation of heat from the body of the insect. This explanation, however, although no other was suggested, did not meet with the general acceptance of the meeting.

Professor Westwood made some critical remarks on the recently published memoir by Dr. Karsten on the *Chigoe* or *Jigger*, insisting on the priority of his own generic name *Sarcopsylla* for the insect, in preference to that of *Rhynchopron*, which was a synonyme of a genus of Ticks (*Acari*).

Mr. H. W. Bates read a memoir on the interesting genus *Agra*, belonging to the family *Carabidae*, in which he described the affinities and habits of this arboreal and nocturnal group, remarkable for lying concealed during the day in curled-up leaves, feeding probably on larvæ, and possessing the power of crepitating by a slight explosion, with a sensation of warmth, and staining of the fingers, when the insects are handled. He also noticed the external distinctions of the sexes, and described sixteen new species from the Amazon region of South America, thus making up a total number of 140 known species of this beautiful group.

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

THE late drying easterly winds and the present clear warm weather have rendered it necessary to supply water to recently transplanted trees, shrubs, and vegetables, and also seedling crops, which are just making their appearance, otherwise they had better be allowed to remain in a dormant state until we have rain, as continued waterings bind the surface of the soil into a hard crust, impenetrable by air and very prejudicial to the germination of seeds. This evil may, however, be in some degree prevented by shading from the sun or covering the soil, so as to prevent evaporation as much as possible; frequent waterings are not then necessary, and the soil is kept in an open porous state, which is of the utmost importance. When the nights are warm, seeds, and herbaceous plants of all kinds, should be watered in the evening, so that the soil may gradually imbibe the water; but if cold nights prevail, an early hour in the morning is the best time for its application. *Broccoli*, as the present warm weather brings it forward so fast, some of it should be pulled up before it is full-grown and laid in a cool place, so as to prolong the season of use. *Cabbages*, when the soil is very hard between the autumn-planted ones it will greatly benefit the plants to fork between them, and after rain to earth up again. *Cauliflowers*, dig up the soil surrounding them with a fork, and afterwards give them a good soaking with water, to be repeated twice a-week during warm weather. *Celery*, all that has been lately pricked out to be shaded and watered until it take good hold of the ground. If it is required very early put

the plants singly into some small pots, and set them in a frame until they get roothold, when they may be fully exposed to the air, but to be kept well watered, or the plants will be apt to run before they attain any size. *Cucumbers*, where they are grown on dung-beds the frame will want raising to allow the plants room and a sufficient depth of soil. Trenches should now be prepared for plants to be grown under hand-glasses; they may be 2½ feet wide and 1 foot below the surface, to be there filled with prepared dung, leaves, and short grass to 6 inches above the surface; good light soil to be put beneath the glasses, and the rest of the dung to be covered with the soil that came out of the trench. *Dwarf Kidney Beans*, make a good sowing for succession; a few to be sown in a pan at the same time to fill up any vacancies. *Lettuce*, give a few of the earliest plants a good supply of water to bring them forward; some of the Coss may be tied up to form hearts. *Mushrooms*, keep a steady heat of from 60° to 65° where there are productive beds; continue to make fresh ones for summer and autumn use. *Radishes*, sow both Long and Turnip-rooted kinds; water beds from which they are to be drawn for use.

### FRUIT GARDEN.

Trained fruit trees, especially Peach and Cherry trees, require particular attention at this season in regard to stopping, disbudding, &c., going over them two or three times so as to prevent a too sudden check to the flow of the sap, and to afford the fruit the protection of the leaves as long as it can be done without injury to the trees. Look sharply after green fly, and apply tobacco water the moment it is perceived. On light sandy soils, however, it may be kept in check by frequent waterings with the engine; but whatever method is pursued, see that it is resorted to before the pest becomes established.

### FLOWER GARDEN.

Trees and shrubs recently transplanted to be watered and immediately mulched with short litter; and the rare and choice kinds to be shaded and occasionally sprinkled overhead with water in the morning. As it is more than probable that where much planting was intended part of it may yet remain undone, we may observe, that some kinds of evergreens may yet be safely removed, taking the precautions to water them at first planting, and occasionally afterwards, to well mulch the surface, and to damp the foliage. We have sometimes found *Hollies*, *Portugal Laurels*, *Evergreen Oaks*, *Red Cedars*, *Arbor Vitæ*, &c., take root more freely now than when planted earlier in the spring, when autumn planting cannot be effected. As a principle in the arrangement of colours, it is generally allowed that the various shades of orange and yellow will class well with the various purples and blues; whites are suitable with the blues, oranges, and reds; whites, however, derange the effect of the yellows, as also the violet shades; whilst the various red or rose-coloured flowers are, as far as colour is concerned, capable of forming a bed by themselves.

### GREENHOUSE AND CONSERVATORY.

The conservatory plants are now making active growth, and should be liberally supplied with water. Those growing in prepared borders to be frequently examined to see that the roots are kept sufficiently moist. At an early hour in the morning give a good washing with the engine or syringe to everything excepting the plants in bloom, the house will then become dry and enjoyable by the forenoon; frequently clean over the borders, remove decaying leaves and flowers; let the paths, stone curbs, shelves, &c., be washed frequently, that the house may present an orderly appearance at all times. More air must now be given, and as the nights become warm allow a little to remain on; this low night temperature will do much to favour the growth of short-jointed wood, which in a house of this description, requiring to be frequently shaded, is difficult to obtain, and at the same time it will prolong the bloom of the inmates. Hybrid Indian *Rhododendrons* and Chinese *Azaleas* will now be in great beauty, and every care should be taken to preserve the blooms from damp and drip. Supply plants liberally with water at the roots, as during their blooming season they require large quantities. Plants out of bloom should be placed where they can enjoy rest for a short time before the new growth commences, otherwise they break

weakly. It should be remembered that when a plant flowers profusely its powers are much weakened, and a lapse of time after blooming, longer or shorter, according to the habit of the plant is necessary to enable it to recover its exhausted energies previous to forming a new growth.

## STOVE.

Attend to the stopping and training of the plants, and afford free-growing subjects plenty of pot-room. Achimenes and Gloxinias filling their pots with roots will enjoy an occasional watering with weak liquid manure. Very little fire heat will now be sufficient if the practice of shutting up early in the afternoon is adopted. Proceed with the re-potting of Orchids as they may require it. Do not use the syringe too freely among those starting into growth, but keep the atmosphere thoroughly moist. See that the specimens on blocks and in baskets are not allowed to suffer for want of water.

## PITS AND FRAMES.

Push forward late-propagated stock, and endeavour to keep the whole growing on slowly. The plants to be exposed to the weather as freely as circumstances will admit, but this should be done by degrees, and never to the extent of browning the foliage and drying up the tissues, and they should never be allowed to suffer from want of water.—  
W. KEANE.

## DOINGS OF THE LAST WEEK.

SUCH a week of dog-day weather, a broiling sun, with a north wind, the temperature during the day reminding one of July rather than April. Where no shading was used, the demands on the water-pail were almost incessant, Strawberries ripening fast, with their pots in turf or moss, requiring water two or three times a-day. Pears and Plums are now in blossom, and Apples are swelling to the opening of their buds. Earnestly do we hope that we shall not have a cold, dreary, frosty May, after such a brilliant April. A few warm showers will make all kinds of vegetation proceed amazingly. Without such showers we shall soon begin to cry out about water. Many things that had to be densely shaded, and even covered up with litter last season, have done better than we could have expected. Such seasons as the last, and as this at present seems to prognosticate, whilst in no way rendering it less desirable to drain gardens and fields, show also the importance of retaining a good portion of that water in pool, pond, or reservoir, before the excess finds its way to ditch or rivulet.

## KITCHEN GARDEN.

Ran the hoe through all growing crops, as Cabbages, Cauliflowers, Onions, Carrots, Asparagus, Sea-kale, &c. Onions and Carrots were rolled with a light wooden roller a week ago. A firm surface makes them tuber and bulb better. Then in a week the spaces between the rows should be run over with the Dutch hoe, which will not only leave a rough surface, but kill every invisible weed. We like to defer this surface-scratching until the ground is pretty well heated, for reasons several times given. We wish our young friends to bear in mind, that as respects freedom from weeds one scuffle with the Dutch hoe will do more good in such weather as we have had lately, in one hour, than hand-weeding could accomplish in a day or two. In fact, much hand-weeding speaks of one of two things, either great deficiency of labour power, or great want of systematic management.

Sowed Radishes, Turnips, and Spinach. Will transplant some winter Onions presently, we find they do best transplanted, merely fastening the roots, not any of the neck in the ground. Sowed a part of the Beet and Salsafy, and will net-cover the former, as last season the birds did not leave a seedling after the red leaves showed above ground. The transplanted crop did beautifully, perhaps all the better that the roots were not very large. We hope that by netting we may dispense with the trouble of transplanting. Why is it that Salsafy and Scorzonera are not more generally served up at table? Good roots are tender and delicious when well boiled. A few of these Beets and Salsafy will most likely run to seed, and, therefore, another sowing should be made about the middle of May. The best way to secure fine roots is to trench deeply, and to have the richest soil at

the bottom, and the poorest at the top. Have it all rich or the richest at the top, and the roots most likely will come like fingers and toes, instead of in one straight root.

Divided and planted Rhubarb and Sea-kale that had been forced. Watered Cauliflowers under glasses, earthed them up by cutting a trench between the rows of glasses, and then, leaving the plants in a basin as it were, the glasses were set on the top of the ridge to give protection at night until they must be removed to give the plants full room. We find ours will come in as soon as we want them. The finest Broccoli, however, is deficient in delicacy after a nice little firm Cauliflower. Watered the first transplanted with manure water; removed the laurel twigs set among them, and slightly forked up the ground, as it is now hot enough to cause them to grow with great luxuriance, and we want to keep moisture in until we see how we shall be supplied from the heavens. The leafy twigs were just suited for placing near the plants of a fresh-planted succession, doing them more good by the shade than lots of cold waterings. Pricked-out younger plants for planting out three weeks or a fortnight hence. In ordinary seasons the Cauliflower is all the better of a little shade from May to September, and therefore it is a good plan to have Peas, say 10 feet apart, and three or four rows of Broccoli between. Watered with house sewage what Cabbages we could, and their appearance next morning showed how much they liked it. Scattered a little wood ashes and soot over the seedlings of the Winter Greens, Broccoli, &c., merely as a precaution, as few slugs or snails can be seen as yet. The only signs of a trail we have yet found were on a Mushroom-bed, where a few holes had been made in some buttons. Celery.—We notice by the market report that Celery makes a good price. We had grown several kinds of Red, but none stood the winter with us equal to the little Incomparable White. We have scarcely lost a head of it, and we are told that not one was run. We took it up some time ago to make way for Onions, and set it with fair balls and a little water to the roots in a heap of ashes, sifted from the furnaces, in a shady place; and though the heads are now smaller when dressed for the table, they are very sweet and nice, and showing as yet no signs of bolting. For general work see last week.

## FRUIT GARDEN.

Ran the hoe through Strawberry quarters, so as to kill all weeds, seen and unseen. Did the same among Gooseberries, Currants, Raspberries, &c. The Strawberries are beginning to show their flower-trusses, and notwithstanding the dryness of the past season, we think there will be plenty of bloom, so far as we have examined. We have a lot of forced ones done bearing, which we shall plant out as soon as we can get at them. We shall also take up and pot a lot of last autumn's young plants pricked out in a border, so as to keep us going before there is plenty in the open air. Of course, we shall select those plants only that are showing bloom. Of these we shall most likely put two or three plants in a seven or eight-inch pot, and plunge these pots in a bed of leaves, with a little bottom heat, and perhaps stick a few branches of trees among them to break the force of the sun's rays. This outside hotbed, uncovered with glass, will soon cause the pots to be crammed with roots, even before the plants come into bloom, and then the pots may be set in any suitable place. This is a plan we used to adopt rather largely at one time for plants to use after April. For early forcing the plants must be prepared in the previous season. This season our first crop had more blind ones than usual, afterwards they have been very good. As a whole, we prefer the runners of one season for fruiting the next, but last season owing to the dryness we could not get runners forward enough, and we used a number of plants that had been taken up as little extra runners in September, pricked out in a border, and taken up and potted in the following July, and these have produced abundance of good fruit. With such plants, and even older ones, our previous experience would have led us to expect an abundant crop; but from the younger ones we generally obtained the finer fruit. The difficulty now is to obtain suitable places for them (see last week), which causes us just now to make our Peach-house a Strawberry-house. We hope to have the most of the pots out before the Peaches want all the sun for colouring and flavour, and the ripening of the wood. The

orchard-house makes also a good fill-gap before the plants come in with their ripe fruit out of doors. We have covered rows and beds out of doors with glass, but with little benefit, unless the weather was very sunny.

Some of our lads are rather hurt about Mr. Rivers, speaking of our being so troubled with insects, and, therefore, without boasting, we may state, that among the many hundreds of Strawberry plants in all stages, and in almost every conceivable place, not an insect of any kind has as yet appeared.

ORNAMENTAL DEPARTMENT.

Here we are pretty well overwhelmed with work. Various reasons, and especially the weather of the last winter and spring, have tended to throw us behind, and it is more perceptible in this magnificent weather. It is a great satisfaction that every man and boy, not only sees that we are a little behind, but is anxious to do the very utmost to break the back of the labour. Work and plenty of it is a most desirable thing, when you feel you can master it, and it shall not, for long at least, master you. Nothing can be more depressing in a garden than finding that do what you will you cannot get up with the work, but that day after day work wants doing, which you cannot execute without letting something of more importance suffer. Even this fine weather has brought its access of labour in watering alone, and especially in such cases where most of the water must be carried in pails or water-barrow. A great amount of bedding-out also increases labour vastly at this season. We have no doubt that we shall be all right by-and-by, but we could not expect the same hearty assistance and co-operation now, if the workmen had been kept out attempting to work in all disagreeable unhealthy weather. There is no mechanism like feet, and especially hands, when directed by thinking willing minds. Some people expect no end of results from human exertion; treating him merely as a machine, they do not give to man the tithe of the attention they bestow upon irrational or inanimate mechanism. We have had thanks innumerable from employers and employed, on what they are pleased to term out-spoken remarks on the labour question, and this encourages us to say a word on gardens, where the *labour-power* is always behind, creating a feeling of lassitude and despair, instead of anxious determination and resolved not-to-be-baffled industry. One of two modes should at once be adopted—*increase of labour power*, or *decrease of ground in keeping*. Many a large garden would be more satisfactory to all concerned, if the half of it were laid down in grass, or in other field crops for a time. One acre properly cultivated and all kept nice will be more satisfactory than two or three acres, that only remind one of the garden of the sluggard overrun with weeds. One acre of lawn properly kept will yield more satisfaction than half a dozen acres, where there is only the pretence of keeping; and a dozen or a score of flower-beds nicely done, will be more pleasing to all concerned than a hundred, or hundreds, in a neglected state.

Proceeded with rolling the lawn before and after mowing; edging sides of walks with the iron, so that they can afterwards be easily clipped during the season. Edged also the sides of borders before digging, and arranging and making up edgings of flowers, and also preparatory to sowing dwarf edgings and other annuals. We seldom sow Mignonette out of doors until May, as then we obtain dense masses, whilst by early sowing we generally get straggling plants. The moving and reducing herbaceous plants, and getting all borders fit for summer residents, are now a main feature of the work, and very suitable the weather is for it, only we wish that the work had been done three weeks ago. We have as yet given no heat to our late vinery, except what the sun gave, with air night and day, but the Vines are becoming so forward that we must now keep them on. We have, therefore, cleared the house of bedding plants; some were set under hurdles thinly spread over with spruce branches, and a great lot of Geraniums, some five or six in a four-inch pot, were placed in a corner to be moved to the Celery trenches. As these were not ready, a little straw was thinly placed over them to afford shade from the sun, and protection from the cold at night. Meanwhile the trenches are being made ready from clearing off last season's Cabbages, digging out trenches 5 feet wide, and 4 feet in the ridges between. Leaf mould and sandy soil are thrown

into the trench, and these pots of plants will be turned out, when, with little attention, they will grow fast until we want them in some three weeks or a month hence. Proceeded with pricking off lots of other things, and put in our last batch of Verbenas, and the pretty dwarf Ageratum, making a bed for them, and pricking them out on the bed some 2½ inches apart, whence they will lift in nice little balls. Those put in a fortnight ago are rooting nicely. Few of our cuttings have had shading this season, but lately the sun has been so powerful that for these later cuttings whitewash is at once drawn down the outside of the glass, and some twice or thrice a-day the little things receive a dewing from the syringe, the great matter being never to allow the cutting to exhaust its juices by any approach to flagging.

What we have said of the late vinery, forces us also to get the Pelargoniums out, or the increased closeness, and the greater heat will be almost sure to bring green fly to nibble at them. We have, therefore been forced to re-arrange the conservatory, taking Daphnes, Camellias, &c., into the vinery, removing the most forward Cytisuses to a sheltered place out of doors, taking out also the most forward Cinerarias now left to an out-door corner, where they may do for cut flowers, and replacing them with different kinds of Pelargoniums. As far as watering would permit, went on potting bedding plants, greenhouse and stove plants, regulating and thinning out climbers, giving a good moist heat in a pit to Caladiums, and setting basket plants, as Stanhopeas, Stag-head Ferns, &c., in tubs of manure water, so as thoroughly to moisten them. In such weather kept the floors of all plant-houses moist, that the air might be both cooled and moistened, &c.—R. F.

COVENT GARDEN MARKET.—APRIL 29.

Within the last few days the aspect of the market has undergone a great change—from scarcity to plenty. Of Cabbages, Coleworts, and Broccoli there is now an abundant supply; and of Lettuces, both Cabbage and Cos, large quantities are brought, but no more than sufficient to meet the great demand for salading, which the heat of the weather has created. Importations of French Lettuce and other salads have been in a great measure discontinued, owing to the heated condition in which they arrive. Asparagus, Sea-kale, and Rhubarb are plentiful, and so, too, are Cucumbers. Of Grapes and Pines there is now a better supply, the former including very fine new Hamburgs from Jersey. Strawberries are quite equal to the demand. A few dessert Apples are still to be had in condition—as Braddick's Nonpareil, Court-pendu-Plat, and Newtown Pippin.

TO CORRESPONDENTS.

\* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

GLASS AND VINES FOR GREENHOUSE (*M. D.*).—All things considered, 21 oz. sheet glass of good quality is the best for glazing houses for fruit culture. Hartley's rough plate is also good, but better for plants than fruit trees. You will need no shade for Vines. They cannot have too much light, whilst they afford an agreeable shade to such plants as require it. The Black Hamburg, Trentham Black, Buckland Sweetwater, Royal Muscadine, Foster's White Seeding, and White Frontignan, do well in a cool house.

DRAINING FERN CASE (*Idem*).—We cannot see in what way you can improve your drainage, except that the cocoa fibre should be placed to the depth of an inch on the perforated zinc instead of under it, and on this the compost, which, instead of being of leaf mould and cocoa-nut fibre, should have loam substituted for the leaf mould, and silver sand would be better than dirty sand from the Trent. Two-thirds cocoa dust and one-third yellow or hazel loam, with a free admixture of silver sand, would be a good compost, and this well mixed and placed on an inch of cocoa fibre over the drainage ought to grow Ferns well. You write of cocoa fibre which is like so much hair, and of no use except for drainage. The right stuff is like sawdust, only it is of a reddish deep brown approaching black when old.

MANAGING COCKSCOMBS (*F. A. H.*).—Pot them at once singly in small pots, using a compost of turfy loam, and grow on in a moist heat. Keep them near the glass, and give a fair amount of ventilation to prevent their becoming drawn. Shift them into pots a size larger when the pots become filled with roots, and give the final shift when the crown shows, using, as before, a compost of turfy loam, with the addition of one-fourth well-rotted hotbed manure, or half well-rotted cowdung two years old. Keep them near the glass in a moist atmosphere, and a temperature of from 60° to 65° at night, and a day temperature of from 70° to 85°. A Cucumber or Melon-frame is a good place for bringing on the plants, and a vinery or other house will do after the plants have received their last shift. They require to be kept well watered, using liquid manure twice a week in order to produce large combs. Keep them near the glass.

PROPAGATING PORCUPINE HOLLY (*Idem*).—Graft it on stocks of the common Holly, now being a good time. Tongue or whip grafting is the best. It is difficult to strike from cuttings, and seeds are not easily procured, otherwise the latter is the readiest mode. Graft quite close to the soil, and on three or four-year-old stocks.

SOWING ZINNIA ELEGANS (*Florum amator*).—Sow forthwith in pans, draining well, and using a compost of turfy loam and leaf mould in equal parts. Sow thinly, and cover lightly with fine soil. Place in a gentle heat, and keep the seedlings near the glass. Keep the soil moist, and give air to prevent the plants drawing. When up and the rough leaves appear, prick off into pans or boxes an inch or two apart, and place in a mild heat for a few days, then remove to a cold frame and harden off. Plant out 9 inches apart in an open situation in a bed of rich soil, watering during dry weather every other day with liquid manure up to the time the plants come into bloom. An inch of well-rotted manure placed on the surface between the plants will assist them in dry weather. Any flowers intended for exhibiting should be protected from rain and sun by a paper shade.

APPLYING LIQUID MANURE (*An Irish Lady*).—You may apply once or twice a week the liquid from the range of offices, diluted with six times its bulk of rain water, to Roses, and all flowering and fruit trees, flowers, and vegetables, from now up to the time of their flowering, or till the fruit is fully swelled. If much diluted with water already it may not be necessary to further dilute the liquid, but take care not to apply it in too powerful doses. It is better not to pour liquid manure near the stem, for there are seldom any active roots there, but by making a trench as you propose, a short distance from the stem, the manure water is likely to be given in the right place. Once a week is not too often to apply it, and it may be given in dry weather more freely than during moist, that being the time when watering is most required. It is much too strong when it leaves a sediment to cake on the ground, and such powerful doses are more injurious than beneficial, unless indeed the sediment remains after diluting the liquid with six times its volume of water. Stir it up, never mind its being muddy looking. If it is not too strong you will gain nothing by keeping each separate.

LEAVES OF THE MALE AUCUBA (*Lizzie*).—For the most part the leaves are variegated, but we have seen some specimens with the leaves nearly entirely green.

SOIL FOR CARROTS IN A FRAME (*B. W. C.*).—Any common light loam, such as is the usual soil of a fertile garden.

UMBRELLA TENTS (*T. C. M. B.*).—We have no doubt that Messrs. Edgington could supply umbrella tents like those exhibited at the June Show at the Horticultural Gardens, South Kensington, last season.

PINE-STOVES (*D. P. H. T.*).—Making, as you propose, that part of the bed lowest which is farthest from the pathway would be very inconvenient indeed.

PEA LEAVES INJURED (*South Notts*).—The scollops eaten out of the edges of your Pea and Bean plants are the work of the striped Pea weevil (*Curculio lineatus*). In Scotland it is called the "Cuddy," because of its grey or donkey-like colour. Dusting the plants with soot whilst the dew is on them might check these marauders.

FLOWER-BEDS, PLANTING (*Dorset*).—In your arrangement of a square into sixteen beds we would keep to the same cross-planting as that with which you have commenced—thus carry out the principle embodied in 1, 1, 2, 2, 3, 3, and 4, 4. To do this you must cross: you must cross 6, 7, and 5, 8, repeated. Your proposed plan, though no doubt it would please many, is just having a scarlet wheel on one side, and a purple wheel on the other side of your carriage; or having that carriage drawn by a black and a white horse instead of by a matched pair. It is for you to determine which you like the most.

FUNGUS IN FERN SOIL (*Bessie*).—Your Ferns will never thrive so long as they remain plunged in the leaf mould full of sticks. Remove them at once, and never use mould containing wood for the growth of Ferns. The decomposition of the leaf mould and rotten wood is the cause of the fungus appearing. We know from experience that Ferns grow much better without either. It is not necessary to plunge the pots in which Ferns are grown, doing so tends to sodden and sour the soil. The fungus is that usually found on decayed wood when surrounded by a moist warm atmosphere, and is very destructive to vegetable life. It is not usually found on wood exposed to the atmosphere, nor indeed does it appear anywhere in a well-ventilated structure. Fresh air is its destruction, though it is very tenacious of life where it once becomes firmly seated. Remove the leaf mould and all the wood it contains, and sprinkle fresh lime where it was. Repot the plants most affected, and frequently stir the soil in which the others are growing. Keep the pots clean, placing them on gravel about the size of a bean. It has a cleanly appearance, and assists in keeping the atmosphere pure, besides preventing the drainage choking. Admit fresh air daily, always avoiding draughts. Many people stew their Ferns—giving them a great heat and an excess of moisture, with very little ventilation. Very few Ferns require a temperature of from 70° to 85° in early spring. *Pteris argyræa* with us attains a very large size in a vinery from which frost is just excluded in winter. It will do in a greenhouse, but better in a house where the temperature is from 45° to 50° in winter, and in summer from 69° to 80°. It is not a stove Fern, though it will live there and make fronds 6 to 8 feet long. As you use cocoa dust we may put you on your guard against keeping it dry under cover, in the potting-shed, or elsewhere to become dry. When this is the case it becomes infested with dry rot and other fungi, and when it is used for potting, a plentiful crop of fungi, more or less inimical to the plants, is the result. It should be laid in a heap in an open situation out of doors, mixed with one-third loam, and turned over twice in twelve months. It is better when it is old, or black, and will then grow almost any kind of plant. Your refuse we see is fresh very slightly decomposed. Use it old.

TIFFANY-HOUSES (*Yorkshire*).—Calico-covered houses, or pits covered with the same, are better than tiffany-covered, and very useful in summer for plants needing a little protection; and in one sense they are better than glass, as admitting enough of light, and yet giving sufficient shade. We have no faith in such covering keeping out 12° of frost, and for nothing besides the above do we consider them comparable to glass-houses. Few tiffany-houses will resist a storm unless extra well secured. For summer purposes they are useful.

GREENHOUSE ARRANGEMENTS (*Inexperienced Amateur*).—We would, under such circumstances, prefer a border inside, and planting inside; but if the border must alone be outside, then there need be no difficulty with a border 7 feet wide at one end, curving to 3 feet wide at the other, as at the narrowest end you need not plant within 5 or 6 feet at that end. We have had heavy crops for about ten years in a small pit, and the earth space is only 2½ feet, by 15 inches in depth. Your border will do very well for a 12-feet-wide house. If there is good soil there now, a little fresh might make all right. If, however, you can, as you say, obtain plenty of fresh loam, then it certainly would be better to use it, and concrete to prevent the roots going down. The concrete should slope from back to front at least 12 inches in the 7 feet, and there should be a good drain lower than the concrete. The concrete is best formed by using the sharp land sand and red gravel, five barrowloads to a barrowload of quicklime, made up quickly as you go along, with just enough of water to mix, and spread out at once 3 inches thick, levelling the top as you go along with the back of the spade. When somewhat set, sprinkle a little dry sand over the surface, roll the whole well, and let it become dry before you put earth upon it. It will then set very hard. The soil will be all the better the nearer the surface it is taken, and may be placed in the border at once, or in heaps, to ferment and sweeten previously. We would make the border from 20 to 26 inches in depth, and in that we would incorporate from twenty to thirty bushels of broken bones, and two or three loads of horse droppings that had been previously heated, and, if possible, some half a dozen loads of lime rubbish. We would add no other manure. Every summer you might give the border from a quarter to a half cwt. of guano, if given at four or five times, and washed in. About 2 inches of horse dung would be safer, raking off the decayed portion when the strength was exhausted. We have no doubt that Lady Downes' Grape, so treated, will bear every year; but early in autumn the border should be covered with dry litter; and if rain and snow are kept out by shutters or tarpauling so much the better. We have so often entered on the subject of the strength of liquid manure, that we would only be giving wearisome repetition by detailing what we meant by weak manure, &c. In many kinds, as house-sewage, drainage from the farmyard, &c., practice must alone determine. It is safest to err on the side of weakness. Thus, we have had drainings from the farmyard, after rain, that we have used freely without the further addition of water. In dry weather we have diluted with from three to five times its bulk with clear water. For good guano we consider 1 oz. strong enough for two gallons; of superphosphate of lime 2 ozs. may be used. For a thirty-six-gallon barrel of water, a peck of soot and a quart of lime will give a strongish clear liquid. For the next filling we would use half the quantity. This will do for such things as Strawberries, Kidney Beans, fruit trees in pots, &c.; but for many pot-plants it would be too strong, and, when used clear for syringing trees and plants, we would dilute more than half. A bushel of horse-droppings, or those of sheep or deer, would, after a week's fermentation, do for sixty gallons of water. We generally make our liquid manure strong, and dilute as we use it. We like all liquid manure to be clear.

WATERING HARDY FERNS (*E. M.*).—It is not only desirable but necessary to water out-door Ferns during dry weather after growth commences. To grow them well the soil should never be allowed to become dry; sprinkling overhead is very beneficial. Rain water is the best, but hard pump water will do if exposed to the air in a tub for a few days prior to using it. By having a tub in the most convenient place, and refilling it after watering, you will always have water ready for use when required. Soapy water will not do, though a weak solution might not cause immediate mischief, yet it is better not to use it, otherwise the more delicate kinds will suffer in consequence.

INSECTS (*J. E. Gilbert*).—The insects are the immature states of one of the Frog-hoppers or "Cuckoo-spit" insects, the white frothy secretion of which must have been visible on the plants, and, if so, the insects might easily have been destroyed by hand. If there were no such "cuckoo-spit," these larvae might have been killed by ordinary fumigation.—W.

**GROUND TEMPERATURE (Fruit-eater).**—The observations of the ground thermometers at 1 and 2 feet deep are read between 8 and 9 A.M. of the same day as that for which the temperature is recorded. The variation of the temperature of the earth at these depths is so slight as to render maxima and minima observations of ground temperature on each separate day of but little practical importance.

**VINES IN POTS NOT FRUITING (A. F. N.).**—Providing they are in 12 or 13-inch pots they will not require anything that way if fresh potted in autumn or prior to starting. If, as yet, in pots of less size, shift them into their fruiting-pots by June, affording good drainage, and using a compost of rich turfy loam chopped, but not sifted. Disbud to one strong shoot as near the base as possible, and cut the upper part away. Train the shoot left at from 1 foot to 16 inches from the glass, and do not rub off the laterals but stop them at the first leaf, and stop them again at every fresh leaf. When the cane has grown to the length of 9 feet stop it, and stop the laterals which will, after this, be plentifully emitted at every leaf. Keep well watered, employing weak liquid manure at every alternate watering; the foliage will be benefited by syringing in the evening. Maintain a moist growing heat within the house. When growth ceases gradually lessen the supply of water and remove the laterals, except a few at the top, cutting them off quite close. When the wood becomes quite brown and hard, and the leaves begin to fall, withhold water, and prune to the length required (5 feet or more) when the leaves fall, and keep in a cool house until wanted for forcing.

**MANURE FOR RHODODENDRONS (J. Edwards).**—Old cowdung, or very decayed hotbed dung, is an excellent application to Rhododendrons, 2 inches deep at a time as a surface-dressing. Your specimens were all dried up. They should be sent in a box covered with a little damp moss.

**BOTANICAL QUERIES (R. C. K.).**—The weed is the common Shepherd's Purse, *Capsella bursa-pastoris*—*Thlaspi bursa-pastoris* of Linnæus. We have no copy of Chi d's book. He, perhaps, speaks of *Medicago lupulina* under its English name of Black Medick or Nonesuch. The dotted circle means "Annual," the circle and arrow "Biennial," the h-like figure "Perennial herbaceous," and the h-like figure "Tree or Shrub."

**CACTUS SEEDLING (W. M. Penn).**—Like others, the flower is richly coloured, but is not so fine or so brilliant as many others exhibited.

**CAMELLIA (B. Hewlett).**—It is one of the very old varieties, and of too usual a colour for us to determine the name from a single and fading flower.

**CATERPILLARS ON PLUM TREES (A Constant Reader).**—They are the caterpillars of the Winter Moth, *Geometra brumata*. As they are on trees in your orchard-house you might easily hand-pick them, spreading a sheet round the tree to catch those which let themselves down. Dust the leaves with fresh white Hellebore powder.

**ROSE TREE PRODUCING STUNTED SHOOTS (Agnes).**—We do not recollect a Rose assuming the character yours has, but we have seen trees of other kinds do so; and the remedy in that case was to rub off a great many of the small shoots, and those left attained the proper dimensions. This plan we would recommend you to adopt, rubbing off one-half of the shoots at once, and a few days afterwards some more; and if you applied some liquid manure to the plant, most likely it would grow on vigorously; but if there were no shoots produced last year but short ones, it is not likely that any flower will be produced until the plant assumes a more healthy habit.

**NAMES OF PLANTS (W. O.).**—1, *Clianthus puniceus*; 8, *Habrothamnus fasciculatus*. The other six, single flowers of *Azalea*, no one could name, the varieties are so numerous. (M. B.).—*Sutherlandia frutescens*. (Jane).—We are unable to give you the information you require about the Cotton-aster, but will make further inquiries. (A nearly M.D.).—1, *Adiantum pubescens*; 2, *A. cuneatum*; 3, imperfect; 4, *Pteris hastata macrophylla*; 5, *Nephrolepis exaltata*; 6, *Asplenium viviparum*; 7, *A. fuscum* var.; 8, *A. fragrans*; 9, *Pteris longifolia*; 10, *Nephrolepis pectinata*; 11, *Onychium lucidum*; 12, *Asplenium marinum*; 13, *Adiantum capillus-Veneris*; 14, *Selaginella*; 15, *Thunbergia Hawtayneana*. (Eliza).—1, *Pleopeltis pustulata*; 2, *Onychium lucidum*; 3, *Polystichum capense*; 4, *Platyroma rotundifolium*; 5, *Asplenium lucidum*; 6, *Goniophlebium neritifolium*; 9, *Cyrtomium anomophyllum*; 10, *Cheilanthes hirta*; 11, *Asplenium bulbiferum*; 12, *Trichomanes speciosum*. (Delia).—1, *Asplenium Adiantum-nigrum*; 2, apparently abnormal *Læstrea patens*; 3, immature.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending April 29th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.
	Max.	Min.	Air.		Earth.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

PIGEONS AND ROOKS.

I do not think that "CHANTICLEER" is right when he blames the rooks for causing his Pigeons to desert their house. I doubt whether he is putting the saddle on the right horse. I will give my experience on the point. I have occupied the same residence for upwards of nine years, there are very large rookeries close to me, one a very few hundred yards from my Pigeon-loft, and I have never lost a single Pigeon. The two birds are in no way antagonistic as far as I can discover. Were I "CHANTICLEER" I should look to some other cause than the rooks for the departure or destruction of my birds. I have kept fancy Pigeons for upwards of a quarter of a century, but never lost a bird. My plan here is this: I devote the room over the coach-house for their loft, it is rather small, and in summer very hot, being ceiled, and having but one small window, which is wired—still the birds have always done well. At the present time, for here it is extremely warm, instead of closing the trap-door, by which I enter from a ladder, I have a moveable door of wire-netting. This ventilates the loft fairly, causing a current of air to pass upward and through the window. At night I close the trap, which is at the gable, near the top of the roof, and, keeping no cat, am annoyed by none. Wherever I have lived I have either taken with me or procured Pigeons, and when I came here I brought my stock from my former home, only a mile as the crow flies, and though they were high-flying Tumblers not one left me. At first, when stocking a loft, I fasten a good-sized wire cage on the landing board, here the Pigeons sun themselves, and gain a knowledge of the scenery near their new home. In three weeks I let them out—all the better

if they have laid. I let them out fasting; usually they are awkward in finding their way in for the first time. Their mistakes in getting up are quite amusing, aiming either too high or too low, but as I always feed inside the loft hunger sharpens their ingenuity. Once back again, I have no further fear about them, and how they coo and testify their delight at getting in again!

As to the almost constant occurrence of bringing new birds home to the others, I always draw the flight feathers of one wing, and enclose them for the night by a wire cage near one nest, this becomes their castle. Next day they have a bath, greatly do they enjoy it if they come from a bird shop, this cleanses and settles them, and greatly comforts the poor wing. Then I have, for the sake of the new comers chiefly, a number of various-sized flower-pots inserted on the floor, placed here and there, upon these they spring ever with but one wing (the first large feather, mind, I never draw, that left shields the new feathers), and they hop from one pot to another, and preen and enjoy themselves. Then in a fortnight they get up to the inside of the entrance, then outside and peep about and learn their whereabouts, until at length they take little flights, and at last, in a month or two, join in the great flight, and naturally come home with the rest.

Pursuing these two plans I have never lost one bird. If "CHANTICLEER" has only provided a box on a pole, however well-planned or pretty, I do not wonder at his birds leaving it. A wooden erection is no home for Pigeons, it is merely "out-of-doors under a chip." The wind whistles through it, the sun warps it, the snow penetrates it and lies on the ledges (and all birds abhor snow), a driving shower wets the eggs of the young, cats come and mew on the ground below, turning up longing green eyes; on one side it burns, on the other it freezes. I do not know whether it is worse in summer or in winter—in the dog-days or

on frosty nights. Verily it is no home, and on the first opportunity the Pigeons rightly decline it, with thanks, I never knew any live for any length of time in one, except Fantails, who looked miserable enough, but being the worst of fliers and, perhaps, the meekest of Pigeons, preferred to put up with present ills rather than fly, or try to fly, to others which might be worse.

If "CHANTICLEER" has no loft or room to afford for his pets, I would recommend him to build a projecting loft from the gable of an outhouse, of stout planks for the floor, and bricks for the sides, and roofed with tiles or slate, with a flat board on the top of the roof, and an open hurdle fastened on the south or sunny side for the birds to rest on. The place should be 6 feet by 4 at the least. By the way, instead of blaming the black rocks, are not the blackguards to be blamed?—in other words, were not the Pigeons stolen? though I incline to the idea if their cot were a wooden construction on a pole, that they left not finding their home comfortable.

Now that I am writing about Pigeons, let me, for the credit of poor maligned human nature, narrate a pleasing circumstance which happened to me only last week. Six years ago, and several before that date, I was accustomed to deal at a certain bird shop. Pigeon books of a former day used to end in some such way as this: "It would be absolutely impossible to enumerate the tricks that are played off to deceive the unwary by Pigeon-dealers. There is not one-tenth part so much jockeyship among horse-dealers as Pigeon-sellers"—in short, Pigeon-dealer and rogue were supposed to be synonymous. But oh! never condemn a whole class, it is harsh, it is wrong. But to return to my tale. Last Friday I called at the old shop in search of some high-flying Tumblers, I am getting up a fight, I found a son and daughter of the late proprietor now, and for long, installed in the old man's place. I chose a pair of birds. I noticed the owners whispering, when the brother came up to me, and touching his hat, said, "I did not know you at first, sir, but my sister says you are the gentleman that once did poor father a kindness, and we therefore beg you to accept the birds." I had forgotten the subject to which they referred, as indeed, it was but a very small matter. I accepted the Pigeons, for I am sure it would have hurt their feelings if I had not, and, of course, I purchased another pair.—WILTSHIRE RECTOR.

### EARTHENWARE PANS FOR NESTS.

PERMIT me to state in your Journal my experience of the use of earthenware shallow pans for laying and sitting, as recommended by Mr. Geyelin.

1st. My hens will not lay in them, but, having removed every other kind of nest, prefer the hard concrete floor, although I have varied the pans by putting in sand, turf, cocoa-nut fibre refuse, &c.

2nd. I have sat five hens in them, and in each case the eggs have been reduced to from six to eight by the hens turning the others out, owing to the turf placed on sand being nearly level with the edges of the pan. My hens (Cochins), therefore, will not take to them at all.

I may add that I have been singularly unfortunate in not having hatched a single chicken; and, in fact, out of three sittings I only found life in one egg, and that two days overdue, which I sacrificed rather than waste the time of the hen in rearing.—PERCY CROSS.

### STOCKING A DOVECOT.

IN reply to Alan Walter, as to how he is to stock his large dovecot, he has only to procure some pairs of Pigeons, confine them there for a fortnight or three weeks, but so that they can see out of the opening, or openings, which is to be their future entrance. It is only necessary to see that the Pigeons are an equal number of cocks and hens. Pairing and multiplying will then proceed without further trouble. Feed them well, and give them plenty of clean water; also, broken mortar from an old wall, and sufficient straw for building their nests, cut up into short lengths of 5 or 6 inches. Before stocking the cot it will be advisable to have it thoroughly cleaned and repaired, all the rat and mouse-

holes securely stopped, all nests well cleaned and repaired, and the whole lime-washed, mixing some flowers of sulphur in the wash. As to what sort to breed that must depend on fancy or inclination, almost any kind will do except the more tender and high-bred fancy breeds.

Blue Rocks. These would be most in keeping with the old monastic dovecot, but they are difficult to procure, troublesome to establish, and not very fast breeders.

Then come the Chequered Dove-house Pigeons of a dark slate colour (often, though improperly, called Blue Rocks). These are more prolific. Or he may choose to have all quite white. They look very pretty, though of a common kind, are equally hardy and good breeders. But if he is quite careless of appearances, then mixed breeds, or mongrels will soon people the house and fill pies. I do not, however, advise any of the before-mentioned. If the nest places are large enough, I would stock it with the largest Runts I could get. Failing these, I would have something to look at as well as eat—all Antwerp Carriers, or Dragons, or else one variety of Toys, of which there are so many to choose from. Buy a few pairs of the approved variety and let them breed until they had stocked the cot, only killing any that were badly marked and odd cocks. In this case all stray Pigeons must be killed whenever they join the flock. As to the Toys, to choose from there are Nuns, Spots, Archangels, Magpies, Spangles, as Suabians, Porcelains, Victorias, &c., all easily procured; and many others that are not so easily obtained would give satisfaction.—B. P. BRENT.

### WHARFEDALE POULTRY SHOW.

THE sixty-eighth annual Show of the above Society took place at Otley, on Friday, the 21st of April.

The show of poultry was superior to any previous one, both as regards the quality of the specimens shown, and the number of entries.

There were also several classes for Pigeons, but the entries were not numerous, though some of the birds were very good. Subjoined is the prize list:—

SPANISH.—First and Second, H. Beldon, Gilstead, Bingley.  
 DORKINGS.—First, J. White, Warlaby. Second, F. R. Pease, Darlington.  
 GAME (Black-breasted and other Reds).—H. Snowden, Bradford, and J. Sunderland, Halifax—Equal.  
 GAME (Any other variety).—First, H. Snowden. Second, H. Beldon.  
 HAMBURGS (Golden-spangled).—First, R. Tate, Leeds. Second, H. Beldon.  
 HAMBURGS (Silver-spangled).—First and Second, H. Beldon.  
 HAMBURGS (Golden-pencilled).—First, H. Beldon. Second, H. Snowden.  
 HAMBURGS (Silver-pencilled).—First, D. Illingworth, Barley, Otley. Second, H. Beldon.  
 BANTAMS (Game).—First, R. Tate, Leeds. Second, W. Taylor, Hunslet.  
 BANTAMS (Any other variety).—First, H. Beldon. Second, F. R. Pease, Darlington.  
 ANY OTHER BREED.—First, H. Beldon. Second, R. Tate.  
 GAME COCK.—First, J. Sunderland. Second, T. Dyson, Halifax.  
 DUCKS (Rouen).—First, H. Beldon. Second, J. Ward, Drighlington.  
 DUCKS (Aylesbury).—First, Suttle & Waddington, Otley. Second, H. Beldon.  
 DUCKS (Any other variety).—First, I. Todd, Clifton. Second, Suttle and Waddington.  
 PRIZES.—Tumblers (Short-faced).—Prize, C. Cole, Bradford. Tumblers (Common).—Prize, R. Ramsden, Armley. Fantails.—Prize, T. Ritchie, Otley. Pouters.—Prize, E. Ripley, Hawksworth. Barbs.—Prize, C. Cole. Owls.—Prize, I. Todd. Carriers.—Prize, C. Cole. Turbits.—Prize, H. Beldon. Jacobins.—Prize, C. Cole. Any other variety.—Prize, H. Beldon.

The Judges were Wm. Smith, Esq., Halifax, and Mr. E. Hutton, Pudsey.

### DOES WILD GARLIC IMPART AN ILL SMELL EITHER TO BEES OR THEIR PRODUCE?

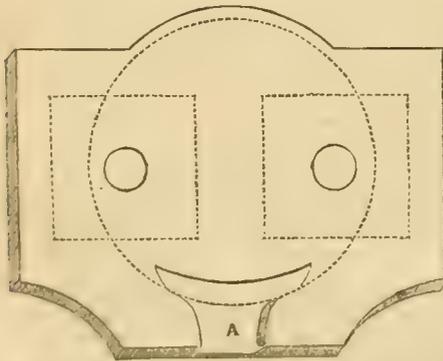

LAST year, about this time, I perceived such an offensive smell proceeding from one of my hives that I felt convinced that that much-written-about disease "foul brood" had shown itself in my apiary. Accordingly, I resolved to destroy the hive forthwith, although it was my strongest and, in every way, most thriving stock, and any others that might be similarly affected. On examination I found the same smell emanating from all my hives, and it was perceptible towards the close of the day from some distance from the apiary. This being the case it was of no use to destroy the hives, at any rate before consulting some well-experienced apiarian. I wrote to Mr. Woodbury, and also to a friend in my own neighbourhood with a request that he

would come and examine my stock. Mr. Woodbury pronounced the offensive smell to be the much-dreaded foul brood. My friend, however, on hearing that our woods abounded with wild garlic, immediately attributed it to that, of which the bees are especially fond. Mr. Woodbury, however, did not seem to think it possible when I made this suggestion to him; and as the same smell has made its appearance this year together with the wild garlic I cannot but fancy that there is some connection between the two, and wish to know the opinions of other apiarists.

The hive in which I first discovered the supposed disease last year was my strongest at the time and most prosperous afterwards, it supplying me, after the stock was filled, with about 40 lbs. of pure honey. If there is any connection between the garlic and this smell, may not other apiarists in neighbourhoods where garlic abounds have been often misled by the smell to think that there was foul brood, and destroyed their hives without any just cause?—A MAN OF KENT.

### HIVES WITH ENTRANCES AT THE TOP.

In answer to your request to furnish you with an outline of my hive, I send a miniature sketch of the wooden top of one of my straw hives. There is no difference whatever in the make of the other part, except in size, from the ordinary straw hive with flat top. If of straw, I make the hives round, about 15 inches inside diameter (not less), by 9½ deep; if of wood, 12 inches by 12 inches square inside, and the same depth. In general, I attach a piece of comb as a guide in the centre, so that the bees may make the ends of their combs come opposite the entrance. The top is securely and permanently fixed to the hive, but the bottom board I never fasten. The latter is made with an entrance to be used if required, but which I keep closed by fitting a piece of wood into it, which is soon made fast by the bees; but if at any time I find them becoming too hot for work, I extract it, and they are soon thoroughly ventilated. Over the doorway in the top board a piece of glass is let flush into the wood, or a bit of zinc may be tacked down upon it. The dotted circle represents the interior circumference of the hive, and the squares show where the supers are placed.

A Passage sunk in the top permitting entrance into the super.

You will observe that I keep the holes in the top for placing the supers over as near the sides of the stock-hive as possible (and a little further back from the entrance than in the sketch), in order to prevent the queen ascending as in large hives, for she rarely troubles the outskirts of her kingdom or colonies with her presence if she has plenty of room in the capital. My greatest difficulty has been to prevent the storing of farina in the supers; but last season I was more fortunate than I had ever been, as I had several supers without any, and one glass with 20 lbs. of pure white honey, with only five cells containing pollen. It was a beautiful sight, but last season was the best that has been in this part for some years.

At first I placed the holes for supers in or near the centre; but whether the bees entered at top or bottom of the old hive, I always had brood in them. Since reading of hives with moveable bars for the bees to construct their combs upon, I have determined to try them. Of course, I shall

make them with entrances at the top; and I cannot help sighing when I think of the many experiments I might have made and the information I might have gained had this plan come under my notice sooner. I fancy my feelings are akin to those of Gordon Cumming, Esq., when he returned from his sporting tour in Africa, where he had been obliged to use the old-fashioned rifle and ball, and found that the Minié had been invented during his absence.

It will be seen that the top is made to support two supers side by side, about 9 inches square by 7½ deep; but I am not very particular as to size or shape, as I use my judgment according to the strength of the stock and the season. The advantage of placing two supers side by side is, that it enables me to work them on the storified system, which I have found to be the best, and by so doing I avoid what your Renfrewshire correspondent seems to be so much afraid of—*i. e.*, the bees taking fright when a full super is raised and an empty one placed under it, and employing their time in undoing their former work instead of being more profitably engaged. The supers are never both filled to the day, and consequently if I raise one there is still one left for the bees to work at.

I imagine if your Renfrewshire correspondent would not practice so much upon his stocks, but leave well alone, he would not have to begin the world so often with beat-outs, as the very greatest enemies the bees have are their own inexperienced masters (myself included); and many young apiarists that I have been acquainted with have at first led me to fancy they were going to do wonders with their management, and have as often lamented the loss of all their stocks, and given up bee-keeping in despair. Upon inquiry I generally found that when the bees were busiest at work their masters were just as busy interfering with them; whilst just at the time when the bees wanted their assistance they took very little if any notice of them.

In my first letter I stated that I had kept the same stock eighteen years. I have no doubt I should have had it now had I not been obliged to remove and scatter my apiary to the four winds, and even since then I have had to dispose of all my stocks but one, after wintering them all safely, and this one I am determined, if possible, to keep under every disadvantage.

I have given the best description in my power, but as there are details which are difficult to describe in writing, I may add that I am able to supply these hives to those who may wish to try them, at 12s. 6d. each.—HENRY STATTLE, Kingsland, Shrewsbury.

### AN ANCIENT BEE-BOOK.

I AM indebted to the Rev. F. de Soyres for the perusal of an old bee-book printed in 1655, entitled, "The Reformed Commonwealth of Bees, presented in several Letters and Observations, to Samuël Hartlibb, Esq.,"\* and said to contain "Many Excellent and Choice Secrets, Experiments, and Discoveries." Among these we find Virgil's blunder repeated, and even professedly verified by,

"An Experiment on the Generation of Bees, practised by that great Husbandman of Cornwall, Old Mr. Carew, of Anthony.—Take a Calf, or rather a Sturk (or Steer), of a year old, about the latter end of Aprill, bury it eight or ten dayes, till it begin to putrefie and corrupt; then take it forth of the earth, and opening it, lay it under some hedge, or wall, where it may be most subject to the Sun, by the heat whereof it will (a great part of it) turn into Maggets, which (without any other care) will live upon the remainder of the corruption. After a while, when they begin to have wings, the whole putrefied carcase would be carried to a place prepared, where the Hives stand ready, to which, being perfumed with honey and sweet herbs, the Maggets (after they have received their wings) will resort."

Next follows a description of a "New Bee-Hive," which is of a circular form, made of wood and to "contain a just bushell within the work." Three of these appear to constitute a set, and the first, when filled, is raised on an empty one, with a circular aperture in the top, and this in its turn

\* Although apparently not very learned on the subject of bees, Mr. Hartlibb seems to have been a man of some literary eminence, and was a friend of the illustrious Milton, who dedicated a work on education to him.

is raised on a third, the top one being ultimately removed full of honey. Access is obtained to the hive through a row of fifteen holes, "three in the midst for the great Bees, and six smaller on each side for the lesser." The drones are, I suppose, meant by "the great Bees;" but the whole arrangement is worthy of that celebrated genius who, having made a hole in the barn door to admit his cat, afterwards cut a smaller one for the accommodation of her kitten!

We next have "a new kind of excellent food for Bees," which is said to be "a notable secret," had from "an old German Captain," and consists of "the planting of Anise near them." This is "proved the best means for multiplying and keeping of them, as also for their breeding of great store of honey." "The Herb being taken and the inside of the Hives rubbed therewith, causeth great multitudes of Bees to enter and become close retainers to those Hives." "That the feeding upon this plant will cause each Stock to engender and thrust out three young ones in one year, within which space they doe else not use to doe so above once. That against the time of their thrusting forth, other Hives ought to be placed next to those from whence they thrust forth, which, as well as also the way leading to the Orifices, are to be rubbed with the Anise in such sort, that the juyce of the Herb may come forth and stick thereunto, and the young Stocks that come forth from the old, will certainly enter into those, and not repair any where else. But in case that upon the neglect any be swarved forth and settled unto some tree, the fault may be amended by rubbing the inside of the new Hive with Anise, and holding it on the top of a long peach unto the bees, who will enter thereinto of themselves as soon as they scent the sweetness of the Anise." We are informed, moreover, that "a Baron in Austria so thrived by this secret that he furnished many Countries with Honey and Wax, and thereby abundantly increaseth his wealth and revenue!"

Then we have "A Translate of a Letter written in High-Dutch," which recommends the prevention of swarming and describes a round straw hive made in sections and very nearly identical with a German "lager" hive shown in the International Exhibition of 1862. I may explain that by "High-Dutch" is meant high-Deutsch or German, so that the fashion of the hives appears to have varied but little during the last two hundred years.

"Tostes of bread sopped in strong Ale" would probably suit Dr. Cumming, and when put into a bee-hive are stated to be "very good and cheap food for bees, of which they will not leave one crum remaining." Flour or meal as a substitute for pollen would also appear to be no new idea, since we are told, that "It will be fit some time to lay some dry Meal or flower of beanes, which dry Meal is given them sometimes as Hey or Corn is to Conies, or upland pasture to Sheep in times of great rain to prevent the rott, and such diseases, as will necessarily follow from continual moist food."

We can, however, only exclaim *credat Judæus!* in respect of the following "notable and approved experiment for improving of Bees.—Take an handful of Melissa (that is a herb which we commonly call Baume). One drachm of Camphire. Half a drachm of Musk dissolved in Rose water. As much yellow Bees-wax as is sufficient. Oil of Roses as much. Stamp the Baume and Camphire very well, and put them into the Wax melted with the Oyle of Roses, scud to make it up into a masse; let it cool before you put in the Musk, for otherwise the heat will fume away most of the scent of it. Take of this masse as much as a haselnut, and cleave it within your Bee-hive. It will much increase the number of your Bees, not only by provoking them to multiplication, but also by enticing many strange Bees to come thither, and abide there. You shall also find, both in Honey and Wax, three times more profit than otherwise you should have had!"

The letters of "Mr. William Mewe, Minister at Eastlington, in Gloucestershire" are, however, remarkable as proving that gentleman to have been much in advance of his age in bee management. Not only had he "transparent Hives" whereby he could show his friends "the Queens Cells and sometimes her person, with her retinue," but he placed stocks of bees in his "bay windowes," of which he declares "their company very harmonious, especially for those that lodge in their Chambers, whether they would wake or sleep,

in so much as I have heard some say (that there have lodged) they would give twenty pound to have and here the like at home."

There is also a letter "written by that much accomplish'd and very ingenious Gentleman, Fellow of All-Soules Colledge in Oxford, Mr. Christ. Wren\* with the figure and description of the Transparent Bee-hive." This so-called transparent bee-hive consists of a set of three octagonal boxes placed one on the other, and is scarcely to be distinguished from the modern Stewarton hive, except in respect to the means of intercommunication between each, which consists of a central aperture instead of bars. There is a window 6 inches by 4 inches at the back of each box, and, what is not a little curious, every box is lined with "rush matt," a plan which I tried some few years ago, believing it to be quite original, and having no idea that I was merely resuscitating a contrivance more than two hundred years old.

Such is a brief transcript of those passages in this ancient bee-book which appear to me the most remarkable, and which may not be without interest to the apiarian readers of "our Journal."—A DEVONSHIRE BEE-KEEPER.

### AN APIARIAN REVIVAL.

THAT the old adage, "Where there's life there's hope," may, in apiarian matters, be pushed a little further, even to the extent, that where there's no seeming life there may yet be a ray of hope, was once well illustrated by an incident in my apiary, a narration of which at this particular season may prove useful as well as interesting.

On a very cold day in the month of March, some few springs ago, towards the close of a three-weeks tuck of withering easterly wind, putting all apiarian operations out of the question, I was mounted on a pruning-ladder, giving some finishing touches to a fruit tree on the garden wall behind the hives, yet could not resist casting an approving sidelong glance at the daring little foragers, who had braved the blast, and now and again were going in with their yellow loads. The extreme quiescence of one stock arrested my attention, causing me to descend from my eminence and administer a sharp tap or two at the entrance; but, alas! no answering, sleepy buzz. The hackle was quickly removed, and then the binding cords securing it to the board, and the stock raised. Ah! how light; its inversion realised my worst fears, causing that pang of regret known only to the bee-keeper, who finds a fine, healthy, well-peopled colony dead, solely from his inadvertence in not administering, possibly, but a few ounces of sugar.

The history of the colony was this. A 3 lbs. 14 ozs. prime swarm hived on the third day of the preceding July in a Stewarton-box, subsequently eked with the intention of its being wrought on my "adapter plan," it was the most liberally fed of all my hives; but the food, as was now too apparent, had been applied at the end of the season to other purposes than winter store. The hive as well as eke were completely combed to the board, while the abundance had so stimulated the breeding of one of the most fertile queens I ever met with, as to cause an addition of late brood seldom seen; besides the little mound of dead on the board, the spaces betwixt the combs were filled to a surprising extent. These loose bees were swept off and the hive replaced. What mattered it, though the foot of my ladder should be entangled with the binding-cord and bring the hive down with a thud on its side, prostrate, on a bed of arabis—the bees were dead. It was only in consonance with its ruined condition that the east wind should for the remainder of the day whistle in its accustomed melancholy strains a requiem through the silent streets of this little city of the dead, varied only by the sharp chirping chuckle of one Titmouse after another hopping triumphantly over the combs, pausing merely to regale himself now and then on all that remained of the once active little workers.

Late in the evening passing with a mat to protect a peach from the keen frost rapidly descending, my eye rested on the fallen hive. I set it on a board and carried it in, placing it in an out-of-the-way corner of the parlour, with the intention of picking out at leisure the dead bees from the vacant cells, so as to put it away prepared for future use.

\* Afterwards Sir Christopher Wren, the great architect.

Before retiring for the night and again in the morning, I took a cursory look at the formation of the combs, the silence of death reigning. During the forenoon while raising the hive with the view of commencing operations, did my eyes deceive me? Could that be a slight quiver of vitality that passed through that beeclosest to the window? Again repeated, there was no mistake. I at once ran in-doors and carried the hive to snug quarters just outside the hearth-rug. Called away, on my return in half an hour how delighted was I to hear a sweet little hum speaking unmistakeably of life, and with it hope. The bung was withdrawn and a soda-water bottle of food took its place; with the increasing heat and increasing vacant space above the food did the hum rise louder, and yet more loud. With what delight I watched the resuscitated separate themselves from the hopelessly defunct mass on the board, and crawl slowly up out of sight among the combs. How anxiously did I subsequently go over this mass, and how relieved was I to find no queen. I next cut off the eke with the suspended comb firmly attached to the cross stick. On the following day the east wind was gone; and the weather being now mild and genial, I set out the hive on its board, carefully wrapped up, and fed on cautiously. A few days more and I was delighted to see pollen carried in. By-and-by the box became crowded and the combed eke was restored, and ultimately my defunct hive happily became one of the best storified colonies I ever possessed.

The narration of the above old story was prompted by hearing the other day of a bee-keeper in this neighbourhood, who at the end of the season had set a fine hive, of which he was not a little proud, in the window of a spare room, there to work under his immediate observation. Chancing to look at it one day during the recent severe weather he found it, as he supposed, quite dead. He carried it into his sitting-room, and chagrined as he was, he hastily broke it up, consigning the bees and empty comb to the dunghill. Some two or three workers that had dropped on the floor during the demolition he afterwards picked up and threw upon the hearth. He was more than astonished in a short time afterwards, to hear them give unmistakable evidence of being "all alive," causing him to conclude that the work of destruction had, to say the least of it, been premature, thereby depriving himself of the accidental good fortune that once befel—A RENFREWSHIRE BEE-KEEPER.

HONEY REMAINING FLUID.

CAN you give a reason why our honey will not harden? It is well-tasted, but as liquid as on the day when it was taken from the super, in June, 1864.—ISA.

[Honey that has been clarified by heat will not again solidify. If, therefore, yours has been exposed to a very high temperature it will always remain fluid. Heath honey has also, to some extent, the same property under any circumstances.]

ANTS IN A BEE-HOUSE.

I AM much troubled with black ants, which are swarming up my bee-house, an open one, and I have failed to discover their nest. I have tied rotten yarn round the legs of the house or stand, but it does not stop them. Is there any danger of these insects making a lodgment within the hive?—B. B.

[Try smearing the woollen yarn with tar. If this does not do nail a bit of sheepskin with the wool outwards round every leg and smear the wool with tar. Ants are not likely to effect a permanent lodgment in a bee-hive.]

OUR LETTER BOX.

FOWLS TREPPARING (F. G.).—Let your solicitor write to your neighbour, giving him notice that if he does not keep his fowls at home you will sue him for damages in the county court. If he does not attend to that notice sue him, as you gave him notice. Prove a sixpenny damage done, and that will render him liable to all the costs. You cannot legally shoot the fowls.

MALFORMED EGG (G. H.).—There is nothing uncommon in such malformations. Keep the hen on rather lower diet for a time.

FLOWERING CURRANT (Birmingham).—The shade of the bush will be grateful to your poultry, and certainly will not be injurious to them in any way.

PIGEON'S EYES WATERING (A. W.).—Bathe the Pigeon's eyes with some cooling lotion. Give the bird a rubarb pill for two or three successive mornings, and avoid hempseed.—B. P. B.

PRESERVING BIRDS' EGGS (C. Hughes).—In selecting eggs for your cabinet always choose those which are newly laid. Make a medium-sized hole at the sharp end with a pointed instrument. Having made the hole at the sharp end make one at the blunt, and let this last hole be as small as possible. This done, apply your mouth to the blunt end, and blow the contents through the sharp end. If the yolk will not come freely run a pin or wire up into the egg, and stir the yolk well about. Now get a cupful of water, and, immersing the sharp end of the shell into it, apply your mouth to the blunt end, and suck up some of the water into the empty shell; then put your finger and thumb upon the two holes, shake the water well within, and after this blow it out. The water will clear your egg of any remains of yolk or of white which may stay in after blowing. If one suck-up of water will not suffice make a second or third. An egg immediately after it is produced is very clear and fine, but by staying in the nest, and coming in contact with the feet of the bird, it soon assumes a dirty appearance. To remedy this wash it well in soap and water, and use a nail-brush to get the dirt off. Your egg-shell is now as it ought to be, and nothing remains to be done but to prevent the thin white membrane (which is still inside) from corrupting. Take a wine-glass, and fill it with the solution of corrosive sublimate of alcohol; then immerse the sharp end of the egg shell into it, keeping your finger and thumb, as you hold it, just clear of the solution, apply your mouth to the little hole at the blunt end and suck up some of the solution into the shell. You need not be fearful of getting the liquor into your mouth, for, as soon as it rises in the shell, the cold will strike your finger and thumb, and then you should cease sucking. Shake the shell just as you did when the water was in it, and then blow the solution back into the glass. If you wish your egg to appear extremely brilliant give it a coat of mastic varnish, put on very sparingly with a camel-hair pencil. Green or blue eggs must be varnished with gum arabic—the mastic varnish is apt to injure the colour.

IS ROUP INFECTIOUS? (H. S.).—It is a disputed point. If the fowls were in robust health they might escape, though put into a roupy yard; but if they were at all out of condition they would catch it. We advise you to have it thoroughly lime-whited, and the floor picked up, and fresh-covered with gravel and earth. We know no means of making a red deaf-ear white. If shown against birds with white ones he would be beaten. Eggs, chopped meat, beer, and white peas are all good for feeding-up Game fowls.

GLASS IN A HEN'S CROP (J. R. G.).—We have never seen so much glass taken from the crop of a fowl, but we have often seen pieces of tobacco pipe and of crockery taken from the crop. Their size and length prevented them from passing into the gizzard, if you mean that as the stomach. The object is the same in every instance: the gizzard requires stones or equally hard substances to grind the food which passes into it from the crop. The birds pick up stones if they can find them—failing that, they take anything they can get to set as stones for the mill. An overloaded stomach, or the presence in it of food they cannot digest, leads them to pick up every and anything. In this instance there is no doubt the presence of the glass in the delicate passages causes exquisite pain. Her reeling backwards was an effort to escape from it. The crop may be opened easily in this way—pick off the feathers down the front about half an inch wide, with a sharp knife cut it open 1 1/2 inch in length; introduce the finger and withdraw all it contains. As soon as it is empty sew it up, and when that is done rub the stitches with plain healing ointment; then sew up the outer skin. This is the part of the operation that requires the most care. The crop is quite distinct from the outward skin, and if the operator is nervous, or the fowl fidgety, it sometimes happens the two are sewn up together. It is a fatal mistake—the outer suture should be sewn closely, and then rubbed with pure grease or ointment, so that every opening is filled up. The bird should then be put in a quiet and darkish place, and fed only on gruel for a few days. If the patient goes on well, ten days, or at most a fortnight, generally make a cure.

SALVIA NEMOROSA SEED (J. W. J.).—This bee-flower is a native of Germany, and not of sufficient beauty to be cultivated as a garden ornament. Perhaps Messrs. Carter, Holborn, or some other of the large seedsmen of London could obtain it.

PAINTING HIVES (J. A.).—Either wooden or straw hives, if otherwise efficiently protected, are, we believe, decidedly the worse for being painted on the outside.

CHLOROFORM FOR BEE-STUPEFYING (Jersey).—Your correction is incorrect, the number of each Journal is at the bottom of its first page, and is not removed with the advertisements when the volume is bound. Several of our correspondents have tried chloroform for stupefying bees, and all agree in declaring the results very unsatisfactory.

TRANSFERRING BEES (Simon).—Transferring a stock is, under any circumstances, far too difficult an operation for a novice, and can only be satisfactorily performed when the new domicile is fitted with either bars or frames, conveniences which are entirely unknown in Nutt's hives. Messrs. Neighbour, 149, Regent Street, and 127, Holborn, publish such a catalogue as you require.

SUPERRING A STOCK (Bert).—Putting on a small glass will not prevent an early swarm. After swarming the remaining bees will rarely work in a super during the same season. If you obtain a strong and early swarm you may super it with every prospect of success. Should the season turn out a good one you may reasonably expect it to leave you in possession of two colonies of bees and a moderate honey harvest.

BUYING BEES (Yorkshire Subscriber).—The best time for purchasing stocks of bees is in the spring, as soon as the dangers of winter are past. Swarms may be agreed for beforehand, hived in your own hives, and should be brought home in the evening of the day on which they issue. Swarms vary in price from 10s. to 20s.; stocks from 20s. to 40s., according to the locality and other circumstances.

LONDON MARKETS.—MAY 1.

POULTRY.

We have but a poor supply, and poultry is consequently dear.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 63.0°, and its night temperature 40.3°. The greatest heat was 86° on the 15th, 1833; and the lowest cold, 25°, on the 15th, 1850. The greatest fall of rain was 1.14 inch.

MISCELLANEOUS NOTES MADE IN HOLLAND AND BELGIUM.

HY does the farming of Belgium so far excel that of both its neighbours, France and Holland? Let a stranger go to sleep in the railway train whilst in either of these countries, and awaking so soon as he has crossed the frontier into Belgium, he will exclaim on looking out of the window, "What an improvement in the agriculture!" In all the three countries the farms are usually very small—from five to twenty acres—but in Belgium alone are they intelligently cultivated; in fact, the farming is gardening on a large scale—every crop is weedless; every watercourse is neatly opened. Spade-culture prevails, and in digging you see that trenching is usually practised to bring fresh soil to the surface. Manure is applied very abundantly both in a solid and liquid state. In the liquid form it is distributed to the growing crops from a tub by a man standing in the cart and delivering it right and left by the aid of a jet.

In the window of a dog-fancier's in St. Martin's Lane may be seen a mild notice that "Puppies' tails are regulated," and if it be true that shepherds' dogs' tails are "regulated" in the west of England through so many generations that at last the puppies come into the world tail-less, then may we not be surprised to hear of young Dutchlings being born with cigars in their mouths. Smoking a cigar is a Dutchman's normal state—he smokes all day—he smokes going to bed—some smoke *in* bed—he smokes first thing when he wakes—and a spittoon filled with sand is in each bed-room to save the carpets from salivary deposits. Fumigation in the plant-houses can rarely be needed—the gardeners fumigate them naturally.

The present Botanic Garden at Amsterdam has been established about two centuries, and is memorable as having had among its curators the two Commelins, and being the first in Europe to cultivate the Coffee tree. There is now there a *Taxodium distichum* which must be about the first of the species introduced from North America; for it is certainly more than two hundred years old—the gardener said three hundred. It must be fully 60 feet high, and its stem 2½ feet in diameter. This is in the open garden, and in the greenhouse are noble specimens of *Encephalartos caffer*, *Sabal mexicana*, *Cycas revoluta*, and *Livingstonia chinensis*; they are from 20 to 30 feet high. But to the garden generally no praise can be given.

In a nursery at Amsterdam we saw a specimen of *Salvia argentea*, a silvery, woolly-leaved plant very different from the silvery plants usually employed for edging by our bedders-out. It is a native of Crete, and introduced more than a century since. It will bear our climate, and deserves to be more frequently employed for that purpose.

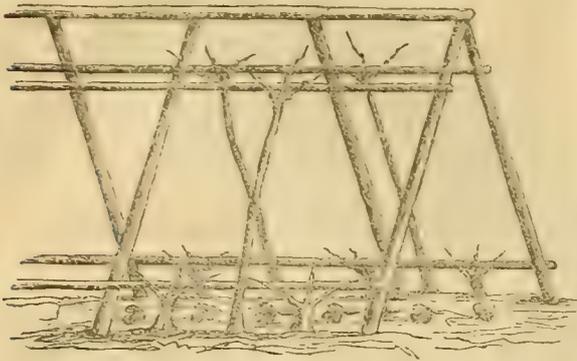

The Zoological Garden at Amsterdam is well supplied with specimens, and is well kept up. Pisciculture has

roused even Dutchmen, and we saw there troughs rearing various species of *Salmo*—*Salmo salar*, *trutta lacustris*, *umbla*, and *fario*. There we also saw excellent specimens of the Breda fowl. They deserve to be introduced into this country. The grey variety, with its dark-laced plumage, is especially handsome. They are of full average size, the adult cock weighing 7 or 8 lbs. We think our Zoological Society would act usefully if they had a poultry department, and kept separately model specimens of all the varieties of our domestic poultry—Turkeys among the rest, which we mention to enable us to say that the servant is represented bringing in that bird—cooked, yet in its plumage—in that wonderful picture of civic portraits by Vander Helst, which would fully recompense any one voyaging to Amsterdam to see—and that "Evening School," by Gerard Dow, for which more than £6000 have been offered—and that candle-illuminated portrait of our William the Third, by Schalken—and that Hare, by Weenix. That picture by Vander Helst abides upon the memory. There are more than twenty life-sized, full-length portraits, each marvelously real, even to the wrinkles of the silk stockings. One cannot but regret that they are all effigies of plain burghers—"The Civic Guard celebrating in 1648 the anniversary of the Treaty of Munster"—not a man among them celebrated for more than being a wholesaler of Schiedam. Perhaps, however, there are some of the great Tulip-speculators among them, so that restores us to our legitimate position; and we may now with restored equanimity journey on to Antwerp, and more comfortable by having relieved our minds by that enumeration, though it has nothing to do with gardening. Let us remark, also, that in a room of one of the railway stations, between Amsterdam and Antwerp, we saw in a hanging-basket one of the trailing plants best adapted for that mode of culture, yet seldom seen in England—*Senecio platanifolius* (?).

Well, we once more pass among those never-changing straight roads and dykes, sentinelled on each side by Willows, monotonous in form and at monotonous distances. We acquired a scrap of knowledge about those trees from Mr. Van Geert. When they are planted their stems are about 2 inches in diameter, and all their roots are cut off at the time of planting, as they emit fresh roots very readily, and these enable the trees to acquire a more rapid growth than those trees from which the roots are unremoved. Each tree is expected to increase a franc in value every year—that is, when felled at forty years old, that they shall each sell for 40 francs.

Mr. Van Geert's nursery is fully worthy of a visit, and if at the same time an introduction is gained to that gentleman, an acquaintance will be made with one who will be called to remembrance when suavity of manner combined with unobtrusive knowledge is named. He vends trained fruit trees extensively, and his mode of training enables him to grow a larger number than usual on a given space. He manages it after the fashion represented on the next page.

The poles of which the trellis is made are about 2 inches in diameter, 6 feet high, and that distance apart. The side

laths to which the trees are tied are, of course, smaller. A rider tree is grown between each pair of dwarfs. Mr. Van Geert has the wood of which these trellises are constructed impregnated with creosote. This is done by pressure by the process employed to impregnate the railway sleepers. Trellises made of wood thus impregnated, and erected in 1858, are now quite sound, whilst others constructed of unimpregnated wood have had to be renewed twice, and in some instances thrice. The creosoting only doubles the cost of the wood, but it more than quadruples the durability. Instead of laths at the sides Mr. Van Geert has recently substituted wide-meshed galvanised wire net, which much facilitates the training. Between the trellises Mr. Van Geert grows a row of Strawberry plants.

On the panels of the entrance hall of his residence are painted large maps, detailing the railroads of Europe. Similar maps are also depicted upon the panels of the rooms at the railroad station, being much more useful and much more ornamental than the usual occupants of these spaces. Antwerp in this as well as in more pretentious works of art is indeed a city of pictures. No one knows what Rubens could do until he has seen the "Descent from the Cross" in this city's cathedral. It is most justly considered the second of the three great pictures of the world. Even his "Elevation of the Cross," which is its near neighbour, looks, when compared with it, coarse, vulgar, and exaggerated.

We may be excused for referring to those pictures, because we have to notice that we have been shown three fragments of the real cross discovered by the Empress Helena. We marvelled that they were each of a different species of wood, and we expected to be told that they only seemed so to our heretical eyes, but the reply was, "the cross of Calvary was formed of three kinds of wood." We certainly were heretical then, but we find tradition bears out the assertion, and alleges that the upright shaft was of Cedar, the cross beam of Cypress, and the inscription was written on a plate of Olive wood. Whether there be any truth in the tradition we know not, but we do know that Rubens's chair, preserved in the Antwerp Museum, is of sturdy Oak, and quaintly fashioned. There were half a dozen chairs closely similar to be sold by auction in the market-place, and we wished that that market-place was Covent Garden, for then purchase would not have been forbidden by difficulty of transport.

Ah! that market-place and many others are thus resumed to "our mind's eye." Whence came all the eggs we saw in those places of merchandise puzzles us—long rows of women in black cloaks and white caps, each two baskets strong, and each basket with at least a hundred eggs in it, layered alternately with straw, were ever present. We did not see many faces spread over the face of the country, and those we did see did not look as if they would help supply to all such baskets as we saw all.

There are a multitude of pots of Mignonette in those markets; but they are apparently for the use of only citizens' wives, but women from the country are intent on taking pots of the "Little Darling" to perfume their homes on the great festival. We have a great mind therefore we shall not,

for when one has a great mind to do a thing one never does it), to relate the legend why the Count of Saxony had a spray of Mignonette in his coat-armour with the motto, "Your qualities surpass your charms;" but we will make the more prosaic observation that the Mignonette of the Belgian markets is a more robust variety than that usual in England. Its leaves are more ovate, thicker, and bullate. One plant is grown in a pot, and its branches, mostly four in number, grow quite upright and as sturdy as minute Mullein plants. We find that we were not singular in this observation; for Mr. Reeves, nurseryman, Bayswater, noticed these peculiarities, obtained some of the seed, and finds the seedlings retain the characteristic differences.

And now let us away to Brussels, not, however, to be tempted by the lace at 200 francs per yard. Yet we will pause to observe that there is something suggestive even to the gardener in that lace. It can only be made from Flax grown in one locality—Hal. In no other place has Flax been produced having so delicate a fibre. Various trials have been made to produce it elsewhere, but they failed. Now, this may teach the owners of mansions not to be rash in concluding that their gardeners are incompetent, because they do not raise certain garden products so excellent as they are raised in some other parts of our islands. We knew a garden that would not yield a crop of Raspberries; we know another in which the Carrot has no tap root; and many of our readers must be acquainted with other illustrations of the lesson taught by the Flax of Hal.

We will at once pass on to the new drive, of two hours' duration, now completing in the forest adjoining Brussels. It is very gracefully planned, and will be a most grateful resort in summer.

With that forest is associated one of Britain's most glorious days. Through this sixty square miles of almost exclusive Hornbeam marched a chief portion of our army to the field to Waterloo.

"Soignies waves above them her green leaves,  
Dewy with nature's tear-drops as they pass,  
Grieving, if aught inanimate e'er grieves,  
Over the unreturning brave."

When our readers are perusing this, since that morning within a month of half a century will have passed. We stood upon the bright green turf that environs the farm of Mont St. Jean, and all was so undisturbed, and the sun shone so bright, and the air was so balmy and so still, that we scarce could realise the fact that even fifty years ago that farm-house was crowded with the lacerated and the dying, and that beneath our feet, wherever we trod, were the bones of the dead of that day.

On we went, and on a grassy bank we picked from a multitude a few Daisies "for remembrance;" and on that bank stands the trunk of a White Thorn, gnarled and scathed by the vicissitudes of many years. By that White Thorn fell the brave old Welshman Sir Thomas Picton, who, with a foreshadowing of what was at hand, wrote home "When you hear of my fall you will hear of a bloody day." The traveller in passing that bank has by his other hand the monument raised by a sister and five brothers to record the high and loveable characteristics of Colonel Gordon.

Near that grew what was called "The Wellington Tree," but it was removed when the soil had to be upheaved to form the lion-surmounted mound raised by the Belgians commemorative of the victory. Nor does the tree deserve regret, for its notoriety was founded on falsehood. Our great commander took a position far away to the right of that tree nearer to Hougoumont, being too old a campaigner to place himself needlessly near the most prominent object on the field, and which would not fail to attract the notice of the French artillerymen.

Here, too, stands the monument recording how bravely fought, and how many were slaughtered of the gallant German Legion—slaughtered comparatively unresistingly from an oversight, for their commander had not secured a sufficient supply of ammunition; and here, with its now trimly enclosed garden, is the little farm homestead, La Haye Sainte, where they fought and fell. The loopholes in its walls through which they fired, and the perforations made by the bullets of their assailants are still visible. By that garden side, too, died, and was buried where he died, that hero of our cavalry—Slaw, the Life-Guardsman, he, who single-

handed, slew so many of the Cuirassiers. Ay! and there is the slope along which they swept to attack our Infantry squares—

“On came the whirlwind—steel-gleams broke,  
Like lightning through the rolling smoke.”

but that steel could carve no entrance into those living quadrilaterals.

“Shaw was a warrior stout and keen,  
And had in many a battle been.”

But they were battles in the prize-ring, for he had been a pugilist, one of the heavy weights, and Viseur, one of the Belgians employed in burying the dead, told that he and his helpmate had to exert all their strength to lift Shaw to his grave. Nor is he without some title to a remembrance in our pages, for he was either the son or nephew of a gardener.

Yonder, in the vale between the two ridges on which the opposed armies were positioned, is another château and garden, of more pretensions, for it has a chapel, and an orchard, and is within a walled enclosure; that château is Hougomont; under that row of trees beyond was the artillery of Jerome Buonaparte, from those cannon was the first fire delivered on the day of Waterloo, and the ball was directed against Hougomont. It was the key of the British position, and was prepared for defence, and was assailed proportionately to its importance. Its orchard trees were shattered to splinters by the French artillery; its roof was battered in; the trunks of the trees around are literally tessellated with the scars where bullets pierced them; the chapel was in a blaze from the French shells, and the flames burnt off the feet of the figure on the Cross, and there, we were assured, they arrested their course. Predatory insects are less reverential, for we never saw a wooden image more worm-eaten. Again and again the French infantry penetrated to the gates of the château, and as often they recoiled before the fire poured upon them by our Guards. The loop-holes in the orchard-walls remain as they were on that day of slaughter, and beneath one, where he fell, is the grave of Captain Lane Blackman, of the Coldstreams. How did that grave contrast with the old Cornus mas which was its neighbour! That tree was a contemporary of the battle, and its shattered trunk is now crowned by but one branch, yet that was profusely covered with its yellow flowers. Nor was that the only contrast—a hundred anecdotes of the sanguinary strife within and around those walls recurred to our memory, and seemed incompatible with the quietude, and the bright sunshine. The songster instead of having suggested to him deeds of “The British Grenadiers,” might have written

“If there’s peace in this world to be found,  
A heart that is humble might hope for it here.”

Yet even on that bright sunny day, a little domestic warfare was only concluding. The present lady of Hougomont is “passing fair,” and the lord of Hougomont is pugnacious when homage is paid to that fairness, and the lady’s father had intervened that day, and peace was being effected, and the lady looked, not penitent, but as if she thought she had the best of it, as she chatted whilst we wrote our names in the album, made obeisance, cut a twig from the Cornus and departed.

Slowly we turned back towards Mont St. Jean, and reaching the high ground again, rested upon a bank that crowned its summit. That bank should never be removed, for from behind it rose our Foot Guards, poured in a volley, gave one hurrah! and finished with the bayonet, the last charge of the French at Waterloo. The decisive moment had arrived, the whole line was formed three deep, dashed down the declivity, and swept the enemy before them.

The Prussians had come up and were assailing the left flank of the French. They debouched from the Forest of Frischermont, guided by a Belgian, whose name deserves preservation. Dumortier was a gamekeeper, who knew every road and path of the forest, and when called upon to act as guide, he led the troops on the high ground so as to come out in the rear of the French—“Then,” as he said, “we shall take them all!”

And, now, warning our readers not to buy walking-sticks of the Waterloo vendors, for no such sticks grow in that locality; bidding them look, but not stop, at the Hotel des

Colonnes, at Mont St. Jean, for there Victor Hugo resided for months whilst he wrote “Les Misérables;” and advising them to have Martin Viseur as their guide, we bid good-bye to Waterloo, and depart for Ghent.—G.

(To be continued).

## AURICULAS IN 1865.

THERE is some wise and cynical philosopher who says that people are never so happy as when contemplating the misfortunes of others—a maxim which I should be very sorry that any of the readers of THE JOURNAL OF HORTICULTURE should either think that I hold, or should themselves maintain; but there is a grain of truth in it, which I conceive to be this, that it does somewhat tend to lessen the depth of one’s own misfortunes when we find that others are sharers in the same calamity. I do not know, but I suppose if the table at an exhibition gave way, and Jones found that his plants were the only ones that had suffered, it would considerably add to his indignation: whereas if Brown and Robinson met a similar fate I am afraid it would considerably lessen the severity of the blow.

Before I left home for a very hurried visit to Ireland I had been horribly disgusted at the appearance of my Auriculas. I had not only lost a considerable number, but I had a very indifferent bloom, plants that looked well only throwing up a truss of three or four pips, and I began to think there must be something very wrong in my treatment, and yet I had managed them as usual. The compost I knew was good, and the plants did not look unhealthy. I was cogitating as to what could possibly be the reason, and proposing to myself some alterations, when I derived a grain of comfort from seeing that at the exhibition of the Royal Horticultural Society on the 15th April only one prize was awarded, and that a second. Oh! oh! I began to think I am not singular, and this long and severe winter has had something to do with it; and when I received from the best Auricula-grower in the kingdom, Dr. Plant of Monkstown, in answer to my intimation that I hoped to pay him a visit, a letter saying that his had never been so bad, I took heart of grace, and began to think I was not alone in my misfortunes. However, as I knew what his Auriculas generally are, I did not quite take in what he told me—that he had nothing to show me, and thought that what he called nothing I should consider a great deal; and so, very soon after my arrival in Dublin, I found my way out to Plantation, and saw with my own eyes the state of his far-famed collection. So far he was right, that I never saw them so poor, while, as I rightly judged, there was still a good deal to see. I found that he had himself been indisposed during the winter, that he had lost the services of his old gardener, and that hence the plants had not been so well cared for as usual, so that he had lost upwards of two hundred plants (this will give some idea of the extent of his collection), while he complained of the very same thing that I had found—the smallness of the trusses. Need I say that while I was really sorry for it, it did give me some little comfort to find that I was in the same plight as one of the very oldest, and certainly the best of growers? There were none of those wonderful trusses of Booth’s Freedom and Hey’s Apollo that I had seen before—the wonder and astonishment of all who ever saw them; but still, as I have said, there were some fine blooms.

George Lightbody. Dr. Plant agrees with our estimate on the other side of the Channel, that it is the very king of Auriculas, combining more really good properties than any other Auricula known, and of this I saw one very fine bloom, and do not wonder that it still maintains its very high price.

Parker’s Metropolitan, self, is a favourite flower of Dr. Plant’s. It does indeed throw a fine truss of bloom, but it has the defect of very soon flying—that is, the colour becomes mottled; and I have known a plant put into a box in fine condition and the next morning to be totally unfit for exhibition.

Fletcher’s Mary Ann is another excellent show flower despite the defect which makes it so distinct amongst all others of its class—namely, the smallness of the eye.

Fletcher’s Ne Plus Ultra was fine, but there were no trusses equal to what I have frequently seen here. It is no

doubt a striking flower, but it has a tendency under high cultivation to become coarse, a fault of a grave character in an *Auricula*—no more to be tolerated in it than in one of the gentle sex.

Campbell's Lord Palmerston was a good green edge, but it has a tendency to throw off offsets—a good plant for a nurseryman therefore, but at the same time preventing it from having a good truss. When it is so caught, notwithstanding being slightly thrum-eyed, it is a nice flower, apparently a seedling from Beeston's Apollo.

Booth's Freedom was the very finest of green edges, even although the trusses were not equal to what I have seen before under Dr. Plant's care.

Colonel Taylor, notwithstanding the high price it still commands, is mainly to be valued for the intense beauty and purity of the edge, for the shape of the flower is starry, and the paste is thin, but nothing can be more pure than the bright green of the edge.

Blackbird. Dr. Plant was loud in his praise of this, which is certainly a most beautiful self and a free grower. It is not, however, I think, equal to Lightbody's Lord Clyde, which was not, however, in this collection, where I fancy the favourite still is Hey's Apollo, than which nothing can be more beautiful. The colour is something like that of Spalding's Metropolitan, but it is a larger trusser than that variety.

Popplewell's Conqueror, albeit the edge has somewhat of a greyish tint in the white, is largely grown here, and is always a commanding flower, but it is not equal to Taylor's Glory, which, despite new additions to the class, I must still regard as the best of white edges.

Heap's Smiling Beauty, it is true, is fine, but it is somewhat cropped, and has not that beautiful flatness and smoothness that marks Glory. I had a good opportunity of comparing all three, and must still hold to the opinion I have mentioned, and yet Glory is scarce, one can with difficulty procure it. Whether this arises from the demand or from a difficulty of growth I know not, but I do know that I have found it very hard to keep.

These were amongst the most remarkable flowers I noticed here, and I should say that while Dr. Plant's collection is very large, it is also very select, and comprises, comparatively speaking, but few varieties. And now, as I sit in early morn jotting down these few notes, in the house of a dear and valued friend, and my eye rests on one of the finest scenes it could well behold, where a rising and prosperous city lies beneath one's feet, embosomed in the midst of verdant hills, and nestling on the banks of a wide and world-renowned river, for the maiden city of Derry is before me with all its historic recollections, so dear to every lover of freedom and of truth, while the past comes with all its powerful recollections of happy days, my thoughts wander off to my own wee lot, and I wonder what I shall have to record of them, whether they have felt the loss of my care, or whether I shall find them full of vigour and life; and as the gathering clouds in the west portend that the long-looked-for rain is coming at last, I (for we all think of ourselves) wonder whether my own little plot is getting the refreshment it needs. Here, too, let me add that *THE JOURNAL OF HORTICULTURE* is making itself heard in this far northern part of the island, and floriculture is making its way. Amidst the signs of progress in "ould Ireland" let not this be unnoticed, for amongst those things that tend to soften and to elevate floriculture must take a prominent place. It cannot take the place of higher and holier things, but it can do much in its own peculiar way, and I am sure all who wish well to old Ireland will say, May the taste for floriculture take the place of the snipe-shooting, the jockeying, and the revelry of the good (?) old times.—D., *Deal*.

#### SOFTENING HARD WATER.

IN reply to Mr. Robson's inquiry in your No. 213, as to the best mode of softening chalky water, I beg to inform him that lime exists in hard water in two different states. Sometimes it exists as a bicarbonate—that is to say, as chalk rendered soluble by carbonic acid. Such is the water of the Thames. In this case there are two remedies—the first is

boiling, which liberates the carbonic acid, and thus precipitates the chalk; the second, which is applicable to large quantities, is the addition of lime water, which, uniting with the acid, becomes itself chalk, and is precipitated with the chalk originally contained in the water. The mixture should remain undisturbed for twenty-four hours, and then be poured off.

But lime often exists in water either as a muriate or sulphate. In this case there is no absolute and perfect remedy, but the best thing is to add kitchen soda to the water; this precipitates the lime as chalk, but the water is not left pure, as it will contain either muriate or sulphate of soda. These, however, are not injurious to roots generally, though not desirable when the water is used for syringing. I believe that much of the evil of hard well water arises from its low temperature.—G. S.

#### ROYAL HORTICULTURAL SOCIETY.

MAY 2.

FLORAL COMMITTEE.—This was the most successful meeting that has been yet held. The number of entries of the plants sent for examination exceeded one hundred, and the collections so numerous sent, containing plants for comparison, were most excellent. The Orchids formed quite an exhibition of themselves. Mr. Williams, Holloway, received first-class certificates for *Phœnicophorium sechellarum*, a new and beautiful Palm, and *Asplenium alatum*, an elegant Fern; a special certificate for a fine specimen of *Cypripedium caudatum*; also a special certificate for his general collection, among which were *Smilax macrophylla*, a handsome variegated-foliaged plant, *Anthurium magnificum*, identical with *Anthurium cordifolium*, and *Maranta Van den Hecke*, too small a plant to judge of its merits. Mr. Turner received first-class certificates for two most beautiful seedling Alpine *Auriculas*, John Leech and Meridian, and a second-class for *Auricula Titian*. Such a collection of Alpines or selfs has never been exhibited in public before: the neatness of the plants, the size of the pips, and the varied tints of colour from dark brown to purplish black, from bright scarlet to pale lilac, commanded universal admiration. For this collection a special certificate was awarded to Mr. Turner, and another was given for his large and beautiful collection of grey and green-edged florists' varieties of *Auriculas*. A special certificate was likewise given for a collection of *Pelargoniums*, which were in great perfection and beauty, also one for the general collection of plants. Mr. Turner exhibited several seedling *Pelargoniums* and *Auriculas*, which were good in their way, but not equal to other varieties.

Messrs. Low, Clapton, sent a collection of very beautiful and interesting Orchids. A first-class certificate was awarded to a new and very beautiful *Phalænopsis*, *Luddemanniana*, a very distinct kind with mottled rosy flowers; and a special certificate was awarded to the collection. Dr. Pattison, St. John's Wood, had also a first-class certificate for *Phalænopsis Luddemanniana*. Mr. Stone, gardener to J. Day, Esq., exhibited an extremely interesting collection of Orchids, containing many valuable kinds. A first-class certificate was awarded to *Phalænopsis* sp. *Moulmein*, a very minute but lovely form of this genus; and a special certificate was awarded to a finely grown specimen of *Dendrobium densiflorum*, covered with its exquisite spikes of yellow flowers. Among others in this collection were *Dendrobium chlorops*, *D. Farmeri*, *D. tortile roseum* (a very fine specimen), and *Cœlogyne corniculata*. There were some of these which deserved to have been specially noticed, but not having been entered for examination did not receive certificates. A special certificate was awarded to this extremely beautiful group of Orchids. Mr. Lawrence, gardener to the Bishop of Winchester, sent an unusually fine specimen of *Epidendrum prismatocarpum*, which received a first-class certificate; and Mr. Lloyd, gardener to C. M. Caldecott, Esq., sent a seedling plant of a variegated form of the Ivy-leaf *Pelargonium*, called Silver Gem; the white variegation was very remarkable, and a second-class certificate was awarded. Mr. Wilson, gardener to W. Marshall, Esq., sent *Dendrobium tortile roseum*, which received a first-class certificate. Mr. Veitch most liberally contributed to the in-

terest of this meeting. First-class certificates were awarded to *Gymnogramma retrofracta*, *Rhododendron Henryanum*, a very promising variety, with large bold white flowers, resembling *R. Gibsoni*; *Primula cortusoides grandiflora alba*, a pure white variety; *Odontoglossum Pescatorei*, a fine specimen; and *Saccolabium curviflorum*. Many other fine Orchids were exhibited in this collection—*Lælia grandis*, *Epidendrum vitellinum*, *Cypripedium barbatum purpureum*, *Calanthe Darwiini*; plants of *Bomarea Caldasii*, *Glycine frutescens alba*, *Peperomia acuminata*, *Azalea Vesuvius*, &c., were also exhibited. A special certificate was given for the whole collection, and a similar award for a collection of *Azaleas* in great perfection.

Mr. Bull sent a large and interesting collection of plants. First-class certificates were awarded to *Aubrietia purpurea variegata*, a very pretty spring-flowering plant, and *Woodsia polystichoides Veitchiana*, a very elegant Fern. In this collection was *Rhododendron thibaudioides*, as unlike a *Rhododendron* as a *Rose*; *Primula intermedia*; *Podocarpus macrophyllus albo-variegatus*; *Aucuba longifolia variegata*, &c. Mr. Parker, Tooting, sent cut specimens of his beautiful *Rhododendron Countess of Haddington*; also an *Iberis*. Mr. Noble, Bagshot, exhibited two groups of *Clematis Fortuni*, and *C. Standishii*, consisting of plants of all sizes, from small cuttings to fine specimens, all of which were profusely covered with most attractive flowers. A special certificate was awarded to each group. Mr. Pilcher, gardener to S. Rucker, Esq., sent specimens of *Phalenopsis Luddemanniana* and *Cattleya sp. amabilis* (?), both of which were awarded first-class certificates. Messrs. Backhouse, York, sent four small plants, each a gem in itself—*Narcissus juncifolius*, *Primula ciliata*, *P. farinosa acaulis*, and *Andromeda hypnoides*—each of which received a first-class certificate. Mr. Wm. Paul sent a collection of the late Mr. Donald Beaton's superb *Nosegay Pelargoniums*, which received a special certificate. The Chairman, the Rev. J. Dix, was requested by the Committee to commend to the Council's special notice the valuable and interesting collection of plants exhibited by Mr. Veitch and Mr. Turner as worthy of the Society's medals.

**FRUIT COMMITTEE.**—Several large tubers of Pink-eyed Regent Potatoes were exhibited by Mr. W. Ingram, gardener to the Duke of Rutland, Belvoir Castle, and which were stated to have yielded at the rate of 20 tons an acre. Lady Dorothy Nevill, Dangstein, sent a pot of jelly made from the fruit of *Passiflora quadrangularis*, and which was highly approved of. The following is the receipt for its preparation: Peel and cut the fruit before it becomes over-ripe; cover with spring water, and allow the fruit to boil till quite tender. Then strain through a jelly bag, measure the juice, and to one pint of juice add half a pound of loaf sugar, the rind of four lemons, and the juice of six; then boil very quickly till stiff enough to turn out of the mould. A Queen Pine Apple of good size and well ripened, and a dish of Apples, were also exhibited.

The scientific meeting held on the same day as the above Committees, was so numerously attended that the capacious Council-room, though closely packed, was insufficient to hold all the audience, some of whom had to stand in the passage. Altogether it was the most brilliant and successful meeting which the Society has ever had, exceeding even the best of those held in its palmiest days, and as Mr. Bateman justly remarked at the conclusion, one among other signs of the returning tide of prosperity.

After the Chairman, W. Wilson Saunders, Esq., had congratulated the meeting on there never having been so fine an exhibition, nor finer things exhibited, the Rev. M. J. Berkeley adverted to some of the objects at the last meeting, and stated that the *Ardisia* then shown by Lady Dorothy Nevill was *Ardisia acuminata*, var. *decipiens* of De Candolle; also, that Dr. Hanstein had been successful in making the sporangia of the *Nardoo* plant germinate, and referred those who were curious about the matter to Fringsheim's Journal. He then passed in review the plants shown on this occasion. Among others noticed were Mr. Bull's variegated *Chrysanthemum* Sensation, the variegated *Aubrietia*, and the variegated *Podocarpus macrophyllus*, which he remarked had one of its branches perfectly white, but such a branch though

it would probably send out a green shoot, could not be propagated from. With regard to the *Clematises Fortuni* and *Standishii*, the latter was perfectly hardy (and the former, coming from the same place, would appear to be equally so), had the merit of flowering when only a few inches high, and that a flower from a plant of that size had been measured by the Committee and found to be 5 inches across. *Rhododendron Henryanum* was stated to be a hybrid of which *R. Dalhousianum* was one parent, and another hybrid of very different appearance was of the same parentage. Another *Rhododendron*, *thibaudioides*, at first sight seemed more like a *Thibaudia* than anything else, but was, nevertheless, a true *Rhododendron*. Some *Rhododendrons* were virulent poisons, *R. cinnabarinum* being one of the worst, and the nearly-related genus *Gaultheria* was also poisonous, though some of the species had edible fruit. *Kalmia latifolia*, too, was poisonous to birds, and those which fed upon it were themselves poisonous. The Alpines from Messrs. Backhouse, *Gloxinia Cordon celeste* and *Anthurium cordifolium* from the Society's garden, which was the same as *A. magnificum* from Mr. Williams, *Woodsia polystichoides Veitchiana*, *Gymnogramma retrofracta*, and other plants were also pointed out. Mr. Berkeley then drew attention to a cone of *Wellingtonia*, gathered by himself at the Marquis of Huntley's, at Orton Longueville, and stated that he had seen a seedling only three years old with cones on it. Mr. Berkeley concluded by stating that Mr. Bateman would make some observations on the Orchids.

Mr. Bateman said, that before he came to Orchids, to show that he had more than one idea in his head, he would bring under their notice a tribe of plants hitherto in obscurity. These plants, he remarked, are widely scattered over the old and new world. They are to be found in Peru, New Grenada, Central America, Japan, and the Indian Archipelago. They are not unknown to botanists, but almost entirely so to horticulturists. His attention was first drawn to them from reading a work by Dr. Poeppig, the Peruvian traveller, who ascended the Andes, and descended the Amazon to Para, with no other companion than his faithful dog; and Dr. Poeppig stated that the young shoots of a *Thibaudia* were so brilliant that they could be seen for a league and a half, wrapping the Peruvian forest in a mantle of flame. Making every allowance for the pure air of the Andes permitting objects to be visible a long way off, he (Mr. Bateman), thought that Dr. Poeppig had been drawing somewhat largely on his imagination as travellers sometimes do; but afterwards having had his attention more closely directed to tropical *Vaccinacæ*, and having procured some *Thibaudias*, he was struck with the colour of the young shoots, one of which he held up in his hand; and imagining what the appearance of a forest would be after the rains, when clothed with such young shoots, he thought it would be doing Dr. Poeppig injustice not to believe his account. The genus *Thibaudia*, continued Mr. Bateman, was named by Humboldt, he believed, after a distinguished foreign botanist, M. Thibaut, a descendant of whom was then in the room. In the north of England and in Scotland, next to the Heaths, the *Vaccinacæ* were the most prominent feature of the vegetation. The Whortleberry, the Cranberry, the Bilberry, and the Cowberry were all native *Vaccinacæ*. There was another *Vaccinaceous* plant which had the distinguished honour of being named after a former President of the Society, *Cavendishia nobilis*, which had been described by Dr. Lindley, but he believed it had not yet been introduced, and it was to be hoped that Mr. Veitch, or Messrs. Low, or Mr. Bull, or some other of our leading nurserymen would stretch out their hands and obtain it. Looking over Dr. Hooker's "Himalayan Plants," he came across two graceful species of *Vaccinacæ* (*Vaccinium serpens* and *V. salignum*), which were found growing at an elevation of from 6000 to 7000 feet, along with Indian *Rhododendrons*, and thinking that the same temperature and treatment would suit them, he planted them together with the *Rhododendrons* in a house facing the west, and one against a wall, but it as well as those in the house failed. One, however, on a bracket in an architectural corridor having the temperature of a warm greenhouse or cool stove, grew well. Tropical *Vaccinacæ* should be grown in niches in the shade, or on brackets, so that their branches might hang down like those of the Indian *Dendrobiums*. Thus treated they

afforded a new element for architectural decoration, and though the specimen of *Macleania speciosissima* which he had brought before the meeting was not so good as it was a fortnight ago, it would give an idea how ornamental the *Vaccinaceæ* were when grown with their branches hanging down; it was foolish to attempt to grow them on the ground. In this class, then, there was a newly-discovered means for the decoration of architectural brackets. At present the plants suitable for that purpose were very limited in number, and these chiefly Ferns; but here we had plants beautiful in their flowers, beautiful in their foliage, and brilliant in the colours of their young shoots, added to which the fruit of some of the species was edible. He now came to Orchids. At the meeting before last, he had called attention to *Cypripedium* as a genus suitable for cultivation by those who had not room for more than one genus, and he thought the plants before them would bear out the justice of his remarks—*Cypripedium Lowii*, from Mr. Day; the dark variety of *C. barbatum* and *C. villosum*, from Mr. Veitch; *C. Hookeriæ*, from Messrs. Low; and from another quarter, *C. caudatum*, the only one which came from the old world. The question might be asked, How could the tail-like appendages of the last be arranged in the flower-buds? but these on first opening had no tails, but after they had burst the tails began to grow. The late Mrs. Lawrence had kept a journal of the rate at which they grew, and found that they elongated from 1½ inch to 2 inches a-day till 18 inches long. W. Wentworth Buller, Esq., of Strete Raleigh, stated in a letter that it would succeed under cool treatment. He would now advert to another great section of the family of *Orchidaceæ*. He believed that if he were asked what Orchids were the most brilliant, he should say the *Dendrobiums*. They competed in numbers with the *Epidendrums* of the new world; but while among the numerous *Epidendrums* there were hardly twenty worth growing, out of nearly as many *Dendrobiums* there were not twenty not worth growing. At this meeting they had before them a group illustrating the genus. There was a magnificent plant of *D. densiflorum*, from Mr. Day; Mr. Marshall, of Enfield, had sent a rising star in the *Orchidaceous* horizon, *D. tortile roseum*; *D. albo-sanguineum*, came from some one else; *D. eburneum*, from Mr. Rucker, white exquisitely marked in the centre with red, which had he thought a great future before it, if we might judge from how other kinds had advanced. When he first saw *D. densiflorum*, of which they had so fine an example before them, it had five little starved flowers, and he thought it hardly worth looking at. Two other species, *D. Farmeri*, and *D. Devonianum*, also came from Mr. Day. *D. chlorops* was seen under disadvantageous circumstances. He would call especial attention to a new *Phalænopsis*, called *Luddemanniana*, which was now exhibited for the first time. It had been considered by Messrs. Low as identical with *Phalænopsis rosea*, but it was new and perfectly distinct. Singularly enough it had been exhibited simultaneously by Mr. Day, Mr. Rucker, and Dr. Pattison, of St. John's Wood, and though small it would probably eventually have twenty flowers on a spike, like *P. amabilis*. When he first began to grow *Dendrobiums*, *D. Pierardi* was considered the most splendid species, by degrees others were imported, till at last *D. Devonianum* was discovered by Mr. Gibson, and this Dr. Lindley called the "King of Orchids," but if it were the King of Orchids, what should be said of that which he held in his hand, *D. Wardianum*. That which he held up before the meeting was but a portion of a spike 5 feet long, bursting with flowers. There was yet one more plant which he had to notice, it was a plant introduced, or rather re-introduced, by Messrs. Low. He was present when the box containing it was opened, and Mr. Low's son stated in his letter that it was found on an old tree across a stream, and that there was nothing equal to it in Borneo. It received the name of *D. Dayanum*, in compliment to Mr. Day. Now a *Dendrobium* called *macrophyllum*, had been introduced thirty-five years ago, but it smelt like Apothecaries' Hall, on which account it was very objectionable; to another subsequently imported, Dr. Lindley had given the name of *anosmum*, because he conceived it to be without smell, but the latter smelt just as badly as *D. macrophyllum*, and he (Mr. Bateman) considered the two as identical. He felt

some doubts as to whether *D. Dayanum* was not the same as *D. macrophyllum*, till his gardener drew his attention to the figure of *anosmum* in "Faxton's Magazine of Botany," when he came to the conclusion that the so-called *Dayanum* was nothing more than *anosmum*. He regretted that this might have the effect of dissociating Mr. Day's name from the species, but as fresh Orchids were coming in by every mail, no doubt some other species would soon be found, to which Mr. Day's name could be attached. Mr. Bateman concluded by reminding the meeting that a show of Orchids would be held on the 13th, and he hoped that all who grew Orchids would contribute to its success.

The subjects brought before the Fruit Committee, and the awards of the Floral Committee, having been enumerated by Mr. G. F. Wilson and Rev. Mr. Dix, Mr. Bateman begged to be allowed to say a few words. He understood that there were three bouquets to be balloted for, and Mr. Wentworth Buller had written that he would send a supply, but from some cause this had not arrived. Whilst speaking of *Vaccinaceæ*, he had omitted to show them the fine large foliage of *Thibaudia macrophylla*, and he had no doubt that the forests of Brazil which had been first ransacked for stove plants, next for Orchids, and then for plants with ornamental foliage, would have to be again explored in search of *Vaccinaceæ*. There was an Orchid, too, which he had omitted to bring under their notice, it was Mr. Skinner's variety of *Epidendrum vitellinum*, from Central America. The flowers of *E. vitellinum* were very suitable for ladies' head dresses, and would last for half a dozen parties, but unfortunately the plants at present in cultivation flowered in autumn and winter, whilst Mr. Skinner's variety flowered in spring, or during the London season, when flowers were more required for the purpose referred to. He had no doubt that Mr. Skinner's plant was the true *Epidendrum vitellinum* of Lindley's "*Sertum Orchidaceum*."

Votes of thanks having been accorded to Mr. Day, and the other exhibitors, and to Mr. Bateman, the latter in returning thanks expressed the great pleasure which he felt at seeing the reviving popularity of the Tuesday shows, and hoped that their success was one among other signs, that the returning tide of prosperity had set in.

Seventeen new Fellows were elected on this occasion.

## TO WHAT PLANTS IS HARD WATER PREJUDICIAL?

MR. ROBSON'S letter on "Hard Water and Can it be Remedied" is one of great importance to persons who reside (as in Hants) in a chalky district, especially in so dry a season as the present. I hope his inquiry will elicit from some of your scientific readers a satisfactory remedy. His letter has raised a question with myself, and no doubt many others, all in a like position. I have lately planted *Araucarias*, *Deodars*, *Cedars of Lebanon*, *Evergreen Oaks*, &c., 10 or 12 feet high; for many weeks past we have had but little rain, which necessitated my gardener to give them spring or well water (very hard) by hydropult syringing as well as at their roots, but some of the *Cedars* are dead, and others show failing vitality.

For the good of the many as well as myself will any of your practical readers enumerate what trees, shrubs, &c., hard or chalky water is known to be prejudicial to? Mr. Robson names one class only, the *Heaths*. Probably, as lime water is a bad solvent, it is equally difficult to be absorbed by the leaves of the trees as by their roots.—J. C. H., *Andover*.

[That hard water is very injurious to a large class of plants there can be but little doubt. Mr. Robson has opened a subject which it is most important should be thoroughly ventilated. In your case, the death of your plants may possibly be attributed to several causes, and it may be that the hard water has had nothing to do with their decay. Indeed, we are strongly inclined to think that it has not. You say that you have lately planted *Araucarias*, *Deodars*, *Cedars of Lebanon*, *Evergreen Oaks*, &c., 10 or 12 feet high. In the first place you must bear in mind what an unfavourable time it has been for newly planted trees for the past six or seven weeks. If the situation in which the trees are planted is very much exposed it would be

scarcely possible to give them sufficient moisture, so that they might retain their vitality, unless some means had been adopted of shading them. As the weather has been you might have syringed them every half-hour overhead, and then found that you could not have kept them moist enough. For the purpose of causing the sap to circulate between the roots and branches in seasons like the present, it is always advisable to stick branches of Spruce or Laurel thickly round newly-planted trees, so that the trees may be protected from the direct rays of the sun. They also help to retain the moisture about the trees for a much longer time after these have been syringed. We remember seeing some years ago a large number of trees of Cedar of Lebanon, Araucaria, Deodar, Evergreen Oak, &c., planted late in the spring in a very similar season to this. They were planted in very elevated positions in the neighbourhood of Dorking, and were constantly watered with nothing but hard water, but similar precautions were taken to those mentioned above with regard to shading, and not a plant was lost. Some of the finest Grapes have been grown in the neighbourhood of Dorking, though the Vines have been watered with nothing but hard water. There is no doubt but that hard water if pumped out of the well and left for several hours exposed to the action of the air would lose a very large portion of its injurious properties. We should, therefore, mainly attribute the loss of your trees to the want of sufficient atmospheric moisture, or there may not have been proper care taken in planting them, they may have travelled a long distance by rail, or delays may have taken place in their transit, so that their roots may have perished before they reached you. All these things should be duly considered before we can arrive at any definite cause of their death.

We have often seen trees planted so carelessly that we are not surprised to hear of their not doing well. Many people will dig a deep hole for them, the tree is placed in the bottom of the hole, care is not taken to spread out the roots, the soil is thrown in carelessly, and the tree is, of course, expected to live. These are two of the rocks on which many split in planting trees. One of the very worst things that can be done is to plant trees deep; the upper or collar roots should be as nearly level with the surface as possible, so that water in any quantity may not lodge about the roots, and a little hillock should be thrown up around the collar of the tree to encourage root-action near the surface. The ripening influence of the sun and air can then have proper effect on the roots, thereby causing the tree to grow less luxuriantly, but helping it the better to mature its growth, and enabling it to withstand severe weather and strong gales of wind, and, if it is a fruit tree, to furnish itself with fruit buds instead of rank wood buds. The next evil to be avoided in planting trees is the cramping and doubling-back of their roots under the bole of the tree, and care should be always taken to have the centre of the hole the highest. When the tree is placed in the hole all the roots should be nicely straightened out, small quantities of fine soil should then be sprinkled amongst them. After the bottom layer of roots has been made fast with soil, which is done by shaking them up with a fork whilst the soil is being thrown about them, they should have a good soaking of water to consolidate the soil about them. This should be carried on until the hole is filled up, taking care that the roots shall be as nearly as possible in the same position after the tree is planted as they were in before it was moved. In giving this explanation of our mode of planting a tree we do not say that your trees were not planted properly, we are only citing instances that have come under our notice, and describing our experience for the benefit of those who may not be acquainted with these important facts.—J. WILLS.]

### GRAFTING MELONS.

ALLOW me to point out to your numerous readers a very interesting experiment which may or may not be new, that of grafting Melons on Vegetable Marrow plants, Pumpkins, or, in fact, on any strong-growing sort of Gourd.

The way and the time to do it should be as follows:—

Raise from seed some plants of a vigorous-growing sort of

Gourd, and when they have attained a growth of 12 or 15 inches cut off the head about 4 inches above the seed-leaves, then take a young shoot from a Melon plant that is approaching to a fruiting state, graft it on the Gourd in the way that is called herbaceous grafting, the most simple of all modes of grafting, as it is merely cutting off a slice from the graft and ditto from the stock, fitting the surfaces of each accurately, and binding the graft to the stock gently with a piece of worsted. When the operation is completed the grafted stock should be placed under a bell-glass in moist heat or in any confined place till a union has taken place, which ought to be in a few days. They should then be cautiously exposed to the growing atmosphere they require, and cultivated as Melons usually are. One caution I must give, the graft or scion must always be kept above the soil, so that it cannot put forth roots—all its food must come from the stock. The effects of grafting are so remarkable in fruit tree culture that I am inclined to think this simple experiment worth trying.—CUCUMIS MELO.

### PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

**BILLBERGIA OLENS** (Stinking Billbergia). *Nat. ord.*, Bromeliaceæ. *Linn.*, Hexandria Monogynia.—Probably a native of Tropical America. Floral leaves crimson; corolla purple. Only the old decaying flowers emit the stench which suggested the specific name.—(*Bot. Mag.*, t. 5502.)

**ASTELIA SOLANDRI** (Dr. Solander's Astelia). *Nat. ord.*, Liliaceæ. *Linn.*, Dicecia Hexandria.—Native of New Zealand, where it grows commonly on the trunks of trees. Flowers yellow, in a very crowded panicle.—(*Ibid.*, t. 5503.)

**CATLEYA QUADRICOLOR** (Four-coloured Cattleya). *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—Native of the banks of the Rio Magdalena, New Grenada. Lip purple, yellow, white, and lilac.—(*Ibid.*, t. 5504.)

**MASDEVALLIA TOVARENSIS** (The Tovar Masdevallia). *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—Native of Tovar, in Columbia, at an elevation of several thousand feet. One of the genus that flourishes in a lower temperature than almost any other genus of Orchids. Flowers white, partially tinged with pink.—(*Ibid.*, t. 5505.)

**MONOCHÆTUM DICRANANTHERUM** (Dicranantherous Monochætum). *Nat. ord.*, Melastomaceæ. *Linn.*, Octandria Monogynia.—Native of the lofty Andes. Flowers pink, "an excessively pretty plant, deserving a place in every warm greenhouse, where it flowers in October."—(*Ibid.*, t. 5506.)

**ARISÆMA WIGHTII** (Dr. Wight's Arisæma). *Nat. ord.*, Aroideæ. *Linn.*, Monœcia Monandria.—Native of Ceylon. Spathe and spadix uniform pale yellowish green.—(*Ibid.*, t. 5507.)

**TEA ROSE**, *Maréchal Niel*.—Raised in the south of France. Lemon-coloured.—(*Floral Mag.*, pl. 237.)

**HOVEA PUNGENS MAJOR**.—Native of Swan River. Flowers purple.—(*Ibid.*, pl. 238.)

**VARIEGATED CHRYSANTHEMUM**, *Sensation*. Flowers white, ranunculus-shaped. Leaves margined regularly with yellowish white.—(*Ibid.*, pl. 239.)

**VERBENAS**.—*George Tye*, purple with lemon-coloured eye. *Charles Turner*, French white, with rosy crimson centre. *Queen of Pinks*, bright pink with yellow eye. All raised by Mr. Perry, and on sale at Mr. Turner's.—(*Ibid.*, t. 239.)

**AUCUBA JAPONICA**.—Female plant with its ripe fruit. "The reason we have been so long ignorant of the full merit of the Aucuba japonica arises out of the fact that the plant is dioecious—producing its stamen-bearing flowers on one plant, and its pistil-bearing flowers on another. All the Aucubas we possessed in this country, till quite recently, were of the latter kind, all, doubtless, the progeny of one originally-imported individual: and hence, as we had no fertilising pollen, our poor Aucuba blossomed uselessly so far as concerned the production of its ornamental berries. To Mr. Fortune belongs the credit of giving us the first male Aucuba; and the spring of 1863 will be famous in the annals of horticulture as that in which English gardeners first saw, through the agency of these male plants of Mr. Fortune's, the first berry-laden bush produced in Europe.

"This plant is that which our plate represents, as grown by Mr. Standish, of the Ascot Nurseries. It also—that is to

say, the green-leaved female Aucuba—is a recent introduction from Japan, and is, no doubt, the typical form of the species, of which our common blotched-leaved Aucuba is one of the many varieties having variegated foliage. Handsome as the spotted Aucubas are, the green-leaved form is still handsomer, on account of the better contrast it presents with the coral-coloured fruit. Mr. Fortune himself observes:—‘The green-leaved I look upon as the most valuable of them all. It forms excellent dwarf hedges, and its glossy evergreen foliage is very ornamental, particularly during the spring months, when the rich coral-coloured berries may be seen peeping out from amongst its leaves.’ Our principal figure represents this plant in fruit, but we are unable to give the true brilliancy of colour, which is that of the finest glossy sealing-wax. In the upper corner of the plate is a small sprig of the blossoms of the male form, which has

wrought such a change in the few plants as yet brought within its influence; and which, when well established and planted out in our gardens and shrubberies, is to work similar changes on the many forms of Aucubas which henceforth—thanks to Messrs. Siebold, Fortune, and Veitch—will adorn them.

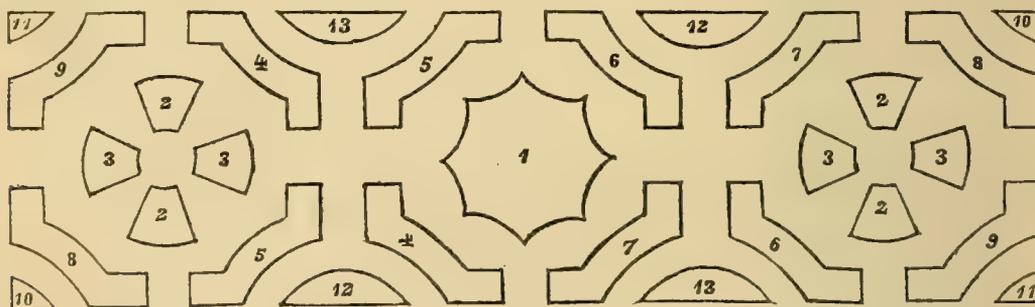

‘That the common variety will be equally ornamental so far as the production of berries is concerned, is now sufficiently evident; for it has already been exhibited in a fruiting state by Mr. Laing, of Twickenham, who produced, at the Royal Botanic Society’s Show, on the 18th of March in the present year, two or three small bushes with the bunches of glossy scarlet fruit very well developed, in which state, on account of the larger size of the berries, it is decidedly more ornamental than the Holly, and that is sufficiently high praise.—(Florist and Pomologist, iii., 65.)

### FLOWER-GARDEN PLAN.

I HAVE lately taken charge of quite a new garden, and the enclosed plan, on grass, has fallen to my lot to bed out at the proper season; and I wish to submit two methods of planting for your inspection, and to ask you to tell me which of the two would look the better, and be the more suited to the plan? As I am not very well versed in the arrangement of colours, I trust I shall not be asking too much if you will criticise the two arrangements, and let me know the result in your Journal. I may also add that I shall have to buy every plant, and that the work is entirely left to me.—T. R.

[Of your two proposed modes of planting we prefer the first, where the beds are to be edged. There is nothing wanting to make such a plan complete of its kind, except a centre bed for 2, 2, and 3, 3, on each side. Your proposed plan of planting has, no doubt, for its object making one figure as it were of the whole group. This gives a reason

for your cross-pairing throughout. No doubt such a plan would look well. Perhaps we are wrong, but we think a simpler plan would look better. The very outline gives you a centre and two wings. This is farther made apparent by the proposed mode of planting, where the centre of the two wings, 2, 2, 3, 3, and repeated, are planted to balance. The simpler plan we would propose would be—make a centre and two wings throughout. Thus, for the centre, instead of banding Christine with Stella, we would make Stella, as the strongest-growing, the centre. Then, instead of crossing 4, 4, we would cross as pairs 4 and 6 and 5 and 7. Then for the wings we would cross 5, 9, and 4, 8, 6, 8, and 7, 9. We would also like to edge 2, 2, 3, 3, repeated. We think this would do more justice to the figure, and be more simple. If you should think so, and you proposed planting, we will criticise. Your own plan will look very well, but pass the above through your mind.]

The beds are 4 feet wide, except the central bed, which is 20 feet wide, and 2, 2, 3, 3, which are 8 feet wide; the

whole is surrounded by grass, except at one end, where there is a conservatory.

No. 1 PLAN OF PROPOSED PLANTING.

- 1, Centre, Christine Geranium; band of Stella; edge, white Verbena.
- 2, 2, Purple King Verbena.
- 3, 3, Mangless Geranium.
- 4, 4, Baron Hugel Geranium; edge, white Ivy-leaf Geranium.
- 5, 5, Alma Geranium; edge, Robinson's Defiance Verbena.
- 6, 6, Prince of Orange Calceolaria; edge, Ariosto Improved Verbena.
- 7, 7, Rose of England Geranium; edge, yellow Calceolaria.
- 8, 8, Stella Geranium; edge, Alma Geranium.
- 9, 9, Heliotrope John Cattell; edge, Tom Thumb Nasturtium.
- 10, 10, Verbena Lady Cotton Shepherd.
- 11, 11, Géant des Batailles Verbena.
- 12, 12, Cloth of Gold Geranium; edge, Lobelia Paxtoniana.
- 13, 13, Mrs. Pollock Geranium; edge, Lobelia speciosa.

No. 2 PLAN OF PROPOSED PLANTING.

- 1, Same as No. 1 Plan.
- 2, 2, Same as ditto.
- 3, 3, Same as ditto.
- 4, 4, Géant des Batailles Verbena.
- 5, 5, Yellow Calceolaria.
- 6, 6, Verbena Ariosto Improved.
- 7, 7, Prince of Orange Calceolaria.
- 8, 8, Stella Geranium.
- 9, 9, Rose of England Geranium.
- 10, 10, Alma Geranium.
- 11, 11, Golden Chain Geranium.
- 12, 12, Cloth of Gold Geranium, mixed with Lobelia Paxtoniana.
- 13, 13, Mrs. Pollock Geranium, mixed with Lobelia speciosa.

### ON THE CULTURE AND CROSS-BREEDING OF STRAWBERRIES.

I STATED in an article at page 233 that if plants of La Constante Strawberry had been anywhere found to suffer from scorching it was to be attributed either to want of attention to timely and effectual watering in dry soil, or to planting or transplanting without having previously removed the ball of earth about the roots. At page 287

‘G. S.’ asks if the latter precept is correct. No one having replied Mr. Eadcliffe thinks it incumbent on me to do so, as I was the author of the proposition; and as some explanation on this point may be useful to other cultivators as well as ‘G. S.’ I gladly undertake to answer his inquiry.

Grow six Strawberry plants in pots for six months or more,

and plant them out without removing the ball of earth and disentangling the roots, which will be matted round the inside of the pots; then take up with the spade other six plants, leaving the earth more or less compact about the roots, and plant both sets of six in the same bed or quarter of the garden in which you plant a dozen Strawberries, the roots of which have been disencumbered of the smallest particle of soil, but which have been spread out in an oblique direction at planting. The latter twelve plants will soon acquire a great degree of vigour, whilst, on the other hand, the other twelve will most likely have a quite different appearance. Whether this planting out or replanting be done in autumn or spring, a month or two afterwards dig up the whole plantation, and it will be found that the plants whose roots were freed of earth will have fibrils and spongioles in abundance, that the adventitious roots from the collar will have insured the re-establishment of the plants, and that these will be in a condition favourable to their withstanding summer's drought and winter's frost. Examine, on the other hand, the plants turned out of pots, or taken up out of the ground, and even after they have been planted six months it will be found that they are not so well established as the others. The difference between the two modes of treatment will, on consideration, be readily understood, and it will be found that Strawberries not properly planted will not resist heat and cold so well as those differently treated. Any Strawberry-grower may make the experiment himself, and report the result, and in less than a year "G. S." could ascertain whether I am right or not in what I advance.

Before concluding I am induced to say a few words on another question, which has been from time to time canvassed in the pages of this Journal and elsewhere—namely, the artificial fertilisation of the Strawberry. For thirty years I have been acquainted with this theory and have carefully practised it, but never with satisfactory results. With regard to one variety making a better mother than another, before plunging into a sea of suppositions it would be far better to examine closely the constitution of the variety, and its botanical character. Does the variety intended to produce seed exhibit at the time the requisite degree of perfection? Is it sufficiently hardy in all seasons? Is the growth firm and moderate? Is the fruit of good quality, smooth-fleshed, produced in long succession, and long-keeping? Has the variety been tried in all ordinary situations and in the different climates of the temperate parts of the globe? Has it been grown for ten years? and has a sufficient amount of evidence been collected on the above points to form a judgment in conformity with the most severe standard of perfection recognised in this branch of culture? When a variety is found to possess all these qualities, that is the variety to save seed from with the view of obtaining an improved variety. It must not, however, be forgotten that perfect seed can only be obtained from healthy adult plants carefully cultivated, and under no extraordinary conditions as regards situation.

When I hear of any one having artificially fertilised a flower of any hermaphrodite Strawberry I doubt the truth of the statement. Let any one examine the flower of the Strawberry before the corolla opens, and on raising the petals he will find that the anthers covering the stigma of the pistil spring from the pits in the forming receptacle. By the time the corolla has opened fertilisation has taken place. On examining with a magnifying glass the orifice of the withered stigma it will be found that the ovary is closed, and that natural fecundation has been already effected. It is then impossible to introduce the pollen of another variety.

There is yet another principle which is pretty generally admitted by those best acquainted with the subject. It is this—The more a variety of fruit, after successive deviations, differs from its primitive type, and the further it is removed from the place of its origin and the conditions of climate which it there enjoyed, the greater is its inclination to vary still further when raised from the seed carefully selected. Placing more reliance on this principle than on the new system of artificial fertilisation, I saved the seed of a dozen plants of *La Constante*, carefully cultivated, and in a situation where it was impossible that the flowers could be impregnated by the pollen of any other variety, and the result was very convincing as to the soundness of the above principle. From these seeds were raised the new varieties

Lucas, La Fertile, Souvenir, Hero, Model, Bijou, &c., all of them differing from each other. This tends to prove that the improvement by seminal variation arises from a combination of circumstances quite distinct from artificial fecundation, and such is my conviction based on a series of facts observed by myself. If any one does not agree with me on this point, I would advise him to experiment for himself, and draw his conclusions from facts actually observed.—J. DE JONGHE, 9, Rue Coenraets, Saint-Gilles, Brussels.

### SOIL FOR RHODODENDRONS.

IN No. 206 of THE JOURNAL OF HORTICULTURE I find attention is drawn to this subject. Having a considerable extent (upwards of fifty acres), of the hardy kinds of Rhododendrons under my charge, and in very different soils, I can fully corroborate all Mr. Robson says with regard to the diversity of soils they will grow in. With regard to the sawdust, I can assure Mr. Robson that that is not the cause of failure, even though it contains that from resinous trees, for we have young seedlings growing in soil freely mixed with it.

Many of the hybrid Rhododendrons, I fear, are far too tender, except in very sheltered places; at least, I find them so here. I obtained a lot from an eminent firm in England, and was assured they were perfectly hardy. I planted them by the side of common kinds, but they would not do; they scarcely kept alive, though the soil was all that could be wished. I removed them to another spot, and they are doing well, but many of them open too early, and are spoiled by late spring frosts. As they are now planted they are surrounded by common kinds that do well, so that there can be no difference as to soil and situation, and the very common Rhododendrons will not succeed well unless they are sheltered considerably from the prevailing winds, especially in spring.

The nature of the soil under Rhododendrons is here very variable, and the most numerous and best seedlings for transplanting are on a gravelly loam, and in the shade. There might be more seedlings at the mountain glens but for the Heath and Moss; where they do take is chiefly by the side of drains.

In my humble opinion the three essentials for the successful growth of the Rhododendron are shelter, shade, and moisture while growing, with a spongy black turf freely mixed with sandy gravel, and not too deep—not exceeding 2 feet. Never plant in what is termed a soapy turf; and when mountain turf is scarce, a good mixture of leaf mould may be used with the turf of a sandy loam pasture cut an inch thick, and laid by until it is half rotten, using sand and gravel freely.

In removing Rhododendrons I have used, with good success, moss wrapped around each plant, and left on when planted; the ball being kept moist the roots soon pass into the moss, and when once started they endure the presence of unsuitable substances much better. Be sure to give a good soaking at planting and again in a week or so, if the weather should set in dry.—GEORGE BECKETT, *Shanbally, Clogheen, Ireland.*

### FRENCH ASPARAGUS.

REFERRING to the correspondence in your Journal lately, "English versus French Asparagus," I requested L'Hérault, of Argenteuil, to send me a bundle, which I have received this day. Thirty-six heads weigh 10½ lbs. I send you herewith ten heads, and shall be glad if you will cook and eat them this day, and decide the question, whether all that is not green is as "tough as the roots of an old Elm tree," as our friend Mr. George Abbey asserted.—H. S. WATSON, *The Cottage, Old Charlton.*

[We obeyed our correspondent's injunction. The ten heads were 9 inches long, 4 inches in circumference in their largest part, and weighed rather over 2½ lbs. Their upper 3 inches were perfectly tender, and the interior of the remaining 6 inches was scarcely less so, but the flavour of the top 3 inches was much weaker than that of our well-grown full-coloured Asparagus.]

## WORK FOR THE WEEK.

## KITCHEN GARDEN.

The hoe should be employed vigorously in eradicating weeds and loosening the soil about young plants where it is hardened by the sun. *Basil* and *Marjoram*, if forwarded in pots, or boxes, may be transplanted on a rich border after a shower of rain. *Beans*, make another sowing of Long-pod, Green Windsor, or any other approved sort. Earth-up the early crops, but if the weather continue dry give them a good watering previous to doing so. *Broccoli*, the seed-beds should be frequently sprinkled with soot, wood ashes, or dust of some kind to preserve the young plants from what is commonly called the fly. The young seedlings sometimes disappear without any apparent cause, but if they were examined about 10 o'clock at night with a lighted candle, the slugs then visible would remove all doubts as to the cause; to destroy them, sprinkle them with quicklime. *Carrots*, thin and water those required for early use. If the first main crops have failed, sow seed of the Early Horn immediately. *Cucumbers*, when the linings of the beds are renewed care must be taken that the heat is not great immediately round the sides of the frame; as a large portion of the roots of the plants will be formed there, water should be given more frequently there than at any other part of the bed. As soon as the ridges are ready for the plants, these may be planted out beneath the hand-glasses, they will require to be covered with mats during the night. *Parsley*, thin the early sowing as soon as it is up. Select some old plants for seed. *Peas*, earth-up and stick the advancing crops, but before doing so they should be watered if the soil is dry. Make another sowing. *Scarlet Runners*, make a sowing in the open ground to succeed those that may have been forwarded in boxes, and which will be ready to plant out about the end of the week. *Tomatoes*, if the plants were raised at the time recommended, they will now be strong and fit to plant out in the end of the week, to be planted singly, and kept well watered until they obtain root-hold. *Turnips*, thin the advancing crops and make another sowing of the Stone to come in in July and August. Where any main crops have failed, no time should be lost in getting in more seed; if the soil is moderately moistened by rain so much the better for sowing the seed, but do not wait for it, for if the seed is sown when the ground is dry and warm, the first shower will be of more service to it than if sown after it.

## FRUIT GARDEN.

Wall trees now require especial attention. Disbudding should be performed at an early stage of growth, and continued at intervals during their season of active growth. Inspect all grafts, removing wild shoots and insects.

## FLOWER GARDEN.

We shall suppose that all the bedding-out plants are in a fine healthy state, the next consideration will then be the arrangement of the colours in the beds, and that arrangement must be left to the taste of the planter, who, if attention has been given to the subject so frequently adverted to in the pages of THE JOURNAL OF HORTICULTURE, will be the best judge of the sins of omission, or commission, on former occasions. As showery weather generally occurs about the middle of the month, advantage should be taken of it to plant the bedding-out stock, beginning with the hardier kinds—such as *Calceolarias*, *Verbenas*, *Scarlet Geraniums*, &c., leaving *Heliotropes*, *Petunias*, *Anagallis*, *Nierembergia*, and such plants as are more susceptible of injury from even slight frosts, until the latter part of the month. All shoots which are long and that are likely to be injured by being blown about by the wind should be pegged down and some small branches stuck amongst the plants to shade them from bright sunshine, and protect them in some degree from the effects of such slight frosts as may occur at this time. Many of the coniferous trees of modern introduction are well worthy of a place on the lawn or in pleasure grounds. If it were in contemplation to add such a noble feature to the home grounds, we would advise, from some experience on the subject, this as the most favourable season for planting them on slightly raised mounds of loamy soil, and to water and stake after planting. The leading shoot of the *Deodar Cedar*, and other naturally drooping shoots, should be allowed free play, for if tied-up straight they are apt to die. *Auriculas* to be potted immediately after their

flowering season. Good turfy loam well rotted, mixed with one-fourth leaf or vegetable mould, one-fourth rotten dung, a small portion of river sand, and a little bone dust if it can be procured, are all the ingredients necessary to grow them to the greatest perfection. Such as are intended to produce seed must not be potted until the seed is gathered.

## GREENHOUSE AND CONSERVATORY.

It will be well to bear in mind during the summer that the shape and sturdiness of every plant will depend in a great measure upon frequent attention to pinching out the point of every strong-growing shoot before it gets too long. A liberal supply of clear liquid manure to be given occasionally—that is, about once or twice a-week, according to the state of the weather or the healthy or luxuriant growth of the plants. Plants in a sickly state, or such as have been recently potted, will not require it; indeed, to such it would be positive injury. *Cinerarias* should receive plenty of air to keep the plants in a healthy state without drawing the foliage; green fly must be kept down by tobacco smoke. The Chinese *Azaleas* going out of bloom should have the seed-vessels picked off, and such as require more pot-room to be shifted, using rich fibry peat with a good sprinkling of silver sand. The *Epacris* that are done blooming, and are now commencing their growth, should be potted; they delight in heath soil like the Indian *Azaleas*. The young stock of hardwooded plants should be growing freely, and will now require careful attention to supply them with a warm and moist atmosphere, with sufficient air at favourable opportunities to secure short-jointed and compact growth. *Balsams* to be frequently shifted into larger-sized pots, and placed in a gentle bottom heat near the glass with sufficient air to prevent them from being drawn.—W. KEANE.

## DOINGS OF THE LAST WEEK.

## KITCHEN GARDEN.

VERY much the same as last week—ground-stirring, weed-killing, Pea and Bean sowing, and watering where absolutely necessary, as in the case of two successions of Cauliflower. After watering the first lot turned out, removed the Laurel twigs which surrounded them, forked over the ground which had become a little hard, and then threw all over the ground, as the forking proceeded, a little half-rotten stubble and litter which had been used for protection in winter. This will secure the plants from the drought, and a little nutriment will be washed out of it if we have a good rain, as the clouds, the dust, the wind, and a falling barometer seem to indicate.

*Mulching*.—Much of the usefulness of mulching depends on the time it is used. For tender and newly-planted trees in winter it is useful for keeping frost and extreme cold from the roots. In spring it is also useful at night for the same purpose, but it acts injuriously in proportion to its openness during fine days in keeping the heat of the sun out of the ground. If kept on during summer it prevents the ground being sufficiently heated, and a clammy, unhealthy, marshy state of the soil is apt to be the consequence. Mulching, then, applied in winter should be moved in warm days in spring. Even scarce as we have been of water in summer we should derive little benefit from mulching before the soil was sufficiently warmed to grow healthily the plants committed to it. We mulch these Cauliflowers because the soil is now warm enough for them. If the rain, notwithstanding the prognostics, do not come, we will mulch about Peas, Beans, and, if possible, Cabbage, Asparagus, &c., with short grass from the mowings of the lawn. It is a mistake, however, to use any such mulching too thick, or, as said above, too soon. Thus in a continuous dry season in the flower garden we would, if we could, mulch *Calceolarias* a month or six weeks before we should think of thus helping *Scarlet Geraniums*. The *Calceolarias*, from being denizens of the hill sides of Chili and Peru, will often have their roots refreshed by the liquid from melted snow, whilst their tops are exposed to a fierce unshaded sun. A cool bottom and a bright warm atmosphere above them just suit the *Calceolaria*, whilst with a moderate supply of moisture at the roots the soil can never be too warm for *Scarlet Geraniums*. Ours were never better than last season,

though for three months they scarcely received water in any form.

Even in cases of mulching in summer to keep the soil moist after it is warm enough, the mulching should never be so thick as to prevent the soil being easily broken by the hoe or fork, as anything like a caked surface would prevent the free action of the atmosphere. Some failures with mulching last season, with an account of which we were privileged, we have no doubt were owing to two causes—mulching too soon and mulching too deeply. One enthusiast covered the surface of the ground so thickly with cocoa-nut refuse in the middle of May that the ground was like Greenland in August. Another used a good coating of half-decomposed hotbed manure, some 6 inches thick, for Broad Beans and Dwarf Kidney Beans in the middle of June, and the garden Beans did tolerably well, whilst the Dwarf Kidney Beans thus coddled became sickly, and did not do half so well. The want of heat in the soil and keeping heat out was the cause of the failure. An inch or two would have been better than such a dressing.

Another friend writes, and wishes to know why we do not say a good word for cocoa-nut refuse for mulching, especially in hot dry summers. We have not done so, not because we undervalue the material, but because we have used it but little out of doors, and are old-fashioned enough to believe in just a moiety of the wonders it is said to accomplish. If he would send us a ton or two for larger experiments we might be induced to change our opinions. We must say, however, that some correspondents proved its admirable adaptation last summer for keeping their flower and other beds moist with little or no watering. They did not put it on too early, and the thickest we were told of was only from 1½ to 2 inches.

Sowed Gherkins, Vegetable Marrow, &c., as we prefer the plants should go out without being stunted. Potted Chilis, Tomatoes, &c. Pricked up the surface soil in Cucumber-beds; made more beds for frames, as detailed the other week. Thinned-out Carrots and Turnips in frames, and exposed Potatoes that had been covered with glass to the sun and air during the day, giving them still a little protection at night. Earthed-up some of the most forward Potatoes in the open garden, and in some frosty mornings scattered a little litter over the tops, which kept them all right.

#### FRUIT GARDEN.

Did a little shortening, nipping, and fastening out of doors, as we have been rather behind this season. Thinned and shortened shoots in orchard-house. Tied-in shoots in Peach-house. Regulated in Fig-pit. Thinned Grapes at all convenient opportunities. Planted-out more Melons, and removed exhausted Strawberry plants, and replaced with fresh. Potted about a hundred young plants, in case we should run out, and plunged them out of doors in a bed of leaves that will yield a nice regular bottom heat. In about three weeks we expect the pots will be full of fresh roots, and then, if the end of May and the beginning of June should be dull and cold, we may make sure of a continuous supply before we have plenty out of doors. In potting these we used rather stiff loam, and rammed it firmly about the roots with a round blunt-ended stick. Not to speak of very early Strawberries, a good supply in April and May is always very creditable to the gardener. Grapes should be thinned with clean dry hands and a covered head. If the hands are naturally clammy it is best to hold the bunch in position with a small pointed stick, and not to touch it. The operator may be certain he does not touch a bunch with his head, whilst the on-looker is horrified at seeing the bunches driven about as if tossed from side to side with a broom.

#### ORNAMENTAL DEPARTMENT.

For general matters see previous weeks' notices and Mr. Keane's directions. Our chief work out of doors has been rolling, digging, planting hardy plants, Gladiolus, &c., and mowing where most wanted, the weather being very unsuitable for the scythe, as we have scarcely had any dew for a week. Prepared beds for bedding-out plants, but we shall be in no hurry with these, as they are growing where they are, and a few things exposed were injured by the late frosts. We think success is more to be secured by well preparing the ground than by too early planting.

Watered some trees and shrubs that were lately planted,

and syringed the tops in hot days. The duller weather will give them a great advantage, as the bright sun was rather trying for them. Mere deluging at the roots with cold water does little good, or rather harm. A syringing of the tops and a little shading would often be more effectual.

*Calceolarias*.—Ours this season are later than usual, and, the cause of which we cannot explain, are lighter in colour than usual, though they have never had an insect on them, and the roots have been all right. They were shut up a long time in winter, and perhaps they may have had too bright sun when exposed. Even now, though greatly improved in the earth pits where they are growing, there are a number of plants not quite so green as we wish to see them, but they seem rooting into nice balls.

*Potting*.—A great deal has been done with the later bedding plants, and also with ornamental-foliaged plants, as Begonias, Coleus, Hydrangea variegata, for the conservatory in the warm months; and as soon as possible we shall overhaul Ferns, &c., in pots. Meanwhile we shall conclude with three notes to oblige inquirers.

1. *A slight hotbed in which at once to insert cuttings of bedding plants*.—The depth of the bed should be proportioned to the time of the spring. This is how our last was made. One foot of long litter mixed with some horse-droppings, so as to raise a little heat, 9 inches of rather warm tree leaves, all trodden, then 2 inches of rotten tree leaves beaten level, then from 2 to 3 inches of sandy loam, and a little leaf mould passed through a half-inch sieve, the riddings being placed over the rough leaf mould. This sandy soil was beaten gently and watered with warm water, and when set on the surface from a quarter to a half inch of road-drift sand was placed over it, and Verbena and other cuttings were dibbled in at about 2 inches apart. In from a fortnight to three weeks they were all struck, and when properly hardened by giving more and more air and then removing the glass altogether, the plants will rise with nice little balls, the rootlets keeping fast hold of the leaf mould at bottom.

2. *Balsams*.—"Many of these after I have grown them to a large size come single. I have but little room. I should like to have only good double ones." Prove them thus before you grow them so large: Pot off all your seedlings in three or four-inch pots. Keep them in these pots, giving them, when the pot is full of roots, a little manure water until they show a bloom or two. Set aside all those that show single flowers, throwing them away, or plant them out of doors; take all the flower-buds off the double ones, give them successional potting, and grow as large as you like, and when you let them bloom you will be sure to have flowers like the first specimens.

3. *Cockscombs*.—"After careful culture many combs are not regular in their growth." To have only good ones in large pots, proceed much the same as with Balsams. Either prick out the Cockscombs 2 or 3 inches apart in shallow pans, or pot them separately in three-inch pots. Keep them in either case until the combs show. If only half an inch in size, you will be able to judge at once of what their shape will be. Then carefully select those with well-shapen combs, shift and reshift and grow on, giving them bottom heat and plenty of top heat and air, until the combs are about large enough to please you. Hardly a comb will disappoint you if you thus start fair. We think they may be had larger by continuous growing without this check at first, but you cannot be so sure of the quality.—R. F.

**BIRMINGHAM ROSE SHOW.**—This great Midland Exhibition of the "queen of flowers" is fixed to take place on Thursday and Friday, July 6th and 7th. Several new features are included in it.

**TO HORTICULTURISTS.**—The fruits of breaking a pane of glass are mostly currents of air.

#### TRADE CATALOGUE RECEIVED.

B. S. Williams, Paradise and Victoria Nurseries, Holloway, London.—*Spring Catalogue of New, Choice, and Rare Plants.*

## COVENT GARDEN MARKET.—MAY 6.

The general supply is good. Pines and Grapes are more plentiful, and forced Strawberries are sent in in large quantities. Pears may now be said to be over, though a few are still to be had. Green Gooseberries have made their appearance in quantity, and are bringing 4s. per gallon. For Lettuces and other salading there is a brisk demand, Cos Lettuces commanding a ready sale at 1s. 6d. per score. The Potato market is still well supplied. New Potatoes from Lisbon are sold at from 3d. to 6d. per lb. English frame Potatoes, at from 1s. 6d. to 2s. the pound.

## TO CORRESPONDENTS.

\*\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

**ROSE LEAVES** (*A Lady Subscriber*).—One of the leaves has been eaten by some one of the leaf-mining grubs. There is no remedy for this but picking off and crushing the leaves attacked. The other leaves exhibit symptoms of starvation. Liquid manure, given twice a-week, and mulching over the roots, would soon remove those symptoms.

**CAPE WATTLE** (*F.*).—"Wattle" is the Australian name for any *Acacia*, but which is the "Cape Wattle" we do not know. Having no information as to the culture adopted by you, we cannot advise.

**ORCHIDS** (*K., of P.*).—Your specimen is *Oncidium luridum* var. *gottatum*. The tint of the green of the buds of *Phalænopsis* vary in colour, but we never saw them absolutely yellow.

**RHODODENDRON SEEDLING** (*C. E.*).—There are many better in the same style, but to form a definite judgment the plant must be seen. Send it to the Floral Committee of the Royal Horticultural Society.

**GUANO LIQUID MANURE** (*Woodbank*).—Two ounces of guano to each gallon of water will make a liquid manure quite strong enough for Roses, &c.

**MANAGEMENT OF BULBS** (*Emily Cook*).—We think you will gain all the information you require for the present by applying to Messrs. E. G. Henderson & Son, of the Wellington Nursery, St. John's Wood, for a copy of their "Bulb Guide." It was published in 1860. Its only fault is its being too concise. We quite agree with you in thinking that a work similar to the one you have described would be very useful to many lovers of bulbs, but it would take a considerable time in framing. We hope, however, to produce a work of this description at some future time. There is a series of essays on bulbs and their culture, by the late Mr. Beaton, in one of our earlier volumes.

**MOWING MACHINE** (*M. H.*).—We know one called "Boyd's;" but we cannot give or publish any opinions as to relative merits. That which you mention is now antiquated; there have been great improvements since that first invention.

**BEETLE DESTROYING PEA PLANTS** (*A Subscriber, Rearsley*).—You must endeavour to render the Pea leaves as nauseous as possible to the Pea Weevil (*Sitona lineata*), by dusting them repeatedly with soot or lime. Increasing the rapid growth of the plants by liquid manure would help to save the crop. The long dry weather has been very favourable to these insects, but rain will greatly thin their numbers.—W.

**WATER CRESS CULTURE** (*Cress*).—As you can have a gentle current of water through the bed every day for a few hours, you will be able to grow Water Cresses as they do in Herts and elsewhere to supply the London market. The trenches in which they are grown are so prepared that, as nearly as possible, a regular depth of 3 or 4 inches can be kept up; and when to be planted the bottom is made quite firm, and slightly sloping, so that the water which flows in at one end may run out at the other. If the bottom of the trench is not sufficiently moist, a small body of water is allowed to enter to soften it. The Cresses are then divided into small sets or cuttings, with roots attached to them; and these are placed at the distance of 3 or 4 inches from each other. At the end of five or six days a slight dressing of well-decomposed cowdung is spread over all the plants, and this is pressed down by means of a heavy board, to which a long handle is obliquely fixed. The water is then raised to the depth of 2 or 3 inches, and never higher. Each trench is thus replanted annually, and furnishes twelve crops during the season. In the summer the Cresses are gathered every fifteen or twenty days, but less frequently during winter. Care is taken that at each gathering at least a third part of the bed is left untouched, so that neither the roots may be exhausted, nor the succeeding gathering delayed. After every cutting a little decayed cowdung is spread over the naked plants, and this is beaten down by means of the rammer above mentioned. After the Water Cresses have been thus treated for a twelve-month, the manure forms a tolerably thick layer at the bottom of the trench, and tends to raise its level. To restore it to its original level, all the refuse should be thrown out.

**VEGETABLE MARROW** (*T. Gillaird*).—Look at p. 31 of our "Kitchen Gardening for the Many," as you say you have our Manuals.

**COVENT GARDEN MARKET PRICES** (*D. P. J.*).—Our quotations are the wholesale and retail prices, and we should think, considering the uncertainty of sale, and the perishable nature of fruits, that the retailer could not give more than half these prices to the growers.

**RESTORING A WATERPROOF TARPULING** (*W.*).—If the tarpauling has been painted, it would be better to paint it again. The best paint is yellow ochre and linseed oil, for it does not crack and become so hard as lead colours. Most varnishes, gums, and mixtures of resin, and similar substances, though waterproof at first, invariably crack and let the wet through.

**BEATON'S GOOD GRACIOUS POLYANTHUS** (*W. W.*).—Messrs. Henderson, Wellington Road, St. John's Wood, bought the stock.

**CATERPILLARS ON APPLE TREES** (*H. H. P.*).—We remember that the late Mr. Curtis, of Glazen Wood, Essex, when his orchard Apple trees were infested by caterpillars, had them dusted thoroughly with the powder of slacked lime. He had a large tin vessel, like the rose of a large watering-pot, perforated with small holes at the top and sides, and with a socket to fit on to a long pole. Only a little lime was put into the vessel at a time, otherwise it was not given out freely. Applied early in the morning, whilst the dew was on the leaves, it adhered readily, and Mr. Curtis told us that it was effectual.

**CUTTING DOWN AN OLD YEW HEDGE** (*R. R.*).—Perhaps it would be best to cut out two-thirds or more of the stems of your Yew hedge, and slash or lay the others in the same way as Thorn hedges are done, adding, at the same time, some manure to the roots. This would at least fill up the gaps and vacancies, and a portion of the green being left, the plants would grow away again. We never like to cut any evergreen down entirely, without leaving some foliage, and Yew is no exception to the rule. We hope the situation is dry, and if stony and porous so much the better.

**SEEDLING WHITE CURRANTS** (*C. Ellis*).—It is possible, but not probable, that you may obtain a better variety of White Currant amongst the seedlings which, we presume, are self-sown, and have come up amongst your trees; at the same time you may have many very indifferent ones. They will bear removal in moist weather, and might be planted in rows 18 inches apart, and the plants half that distance in the row. It is possible some of the strongest may make a shoot strong enough to bear next year, but the greatest number will require another season's growth.

**CUTTING THE SHOOTS OF PINUS EXCELSA** (*Idem*).—Unless the tree is very irregular in growth, we would hardly advise much cutting to be done, as we certainly prefer a little extra growth on one or two sides to a clipped-looking specimen. If, however, any of the side branches point upwards, as if disposed to compete with the proper leader, the tips of these might be cut off at once; or, what is better, as we sometimes treat *Thuja*, and similar plants, bend the shoots downwards, and secure them in that position with a string.

**PRUNING APPLE TREES LATE IN THE SPRING** (*P. Bull*).—It would certainly have been better had you pruned your young Apple trees before they commenced growing, but you may do so yet to a limited degree, so as to give them the shape you wish them to take; but if your trees were only planted in the past winter, it is quite as well to let them alone for the first year, and next winter to prune-in rather severely. It is considered bad practice to closely prune-in a young tree newly planted, as it tends to encourage suckers from the stock; but an old tree, with its roots necessarily much reduced by transplanting, may have its head cut-in in proportion. If, therefore, your trees are young, you had better let them alone for the present summer, and cut-in as you like when the leaves have fallen in autumn.

**BOOK** (*G. R.*).—The book required is called "Arbres Fruitières," par M. A. Dubreuil (fifth edition), at Victor Masson & Sons, Place de l'École de Médecine, Paris. Price about 3s. in London.

**NAMES OF PLANTS** (*J. McG.*).—1, *Asplenium viride*; 2, *Blechnum occidentale*; 3 and 17, vars. of *Asplenium bulbiferum*; 4, 10, 13, *Lastrea Filix-mas*; 6, 7, *Lastrea dilatata collina*; 11, *Athyrium Filix-foemina rhodionum*; 14, *Asplenium adiantum-nigrum*; 16, 19, *Pteris hastata macrophylla*; 15, *Blechnum pectinatum*; 18, *Pteris hastata*; 20, *Cytidium falcatum*; 21, *Polyetichum aculeatum lobatum*; 8, *Lastrea omula*; 6, 9, 12, very imperfect. The Grape was smashed. The roots of the Vine are probably too cold. (*A. R.*).—*Lonicera alpicana*. (*T. Edwards*).—1, *Amygdalus nana*; 2, *Anemone apennina*; 3, *Corydalis leuca*; 6, *Epidemium alpinum*. Nos. 4 and 5 cannot be satisfactorily named from such scraps. They are most likely 4, *Epidemium violaceum*, and, 5, *E. macranthum*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending May 6th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

APPRECIATING CHICKENS' MERITS.

It is among the great charms of our pursuit that it brings us in contact with many very amiable and excellent men—members of the clergy. We were lately talking to one who said he has certain sermons he always preaches at certain times of the year, and when some of his hearers tell him the sermon is an old acquaintance he asks them if they have acted up to its requirements, or if they have derived all possible benefit from it. We are somewhat in a similar position: there are subjects that belong to seasons, and this is one of them. Letters come in upon us, asking how soon an accurate judgment may be formed as to the merits of chickens, and suggesting the obligation that would be conferred by us on amateurs if we published some papers on the subject. We have done so every year and we do so again.

It is of no use to look for perfection, and if all faulty chickens are to be drafted you may make a clean sweep, but there are deformities and deficiencies that say plainly the subjects of them are fit only for the market and table. Have no mercy upon them. That which is sickly or deformed always seems to have a claim on the sympathy of those who are in a position to protect it, and the crooked chicken, or the poor little darling of the brood, are sure to have protectors among the ladies of the family. We have known a crooked tail to save the life of a chicken, and the greatest favourite we ever saw was one that had a habit of carrying its head as though it were continually looking round a corner. It is useless to save such animals. Chickens sell well at this time of the year—fatten them and send them to market, or, if you prefer, eat them. Nothing is nicer than a spring chicken. It is of no earthly use to suppose they will die. Such creatures seem to be endowed with longevity. Rats won't kill them; if there is an incursion of these pests into the poultry-house they always take the best. Thieves won't steal them—in fact the only use these poor "creturs" can be is to prove a robbery. They form a link in evidence. It is hard to swear to a fowl picked and trussed with the head cut off, but easy when there is a particular foot, or a crossed bill, or a crooked tail. The pest of the neighbourhood in a lonely parish was brought to justice by one of these "cripples." He was the planner of all the roost robberies, and the receiver of the goods. His instructions were never to bring away a pet or a cripple, but they did once; they brought away a screaming, flying, very hump-backed Hamburg hen. Every one knows how they scream. She was taken with a lot of choice Dorkings that were in the house. The receiver broke out into a passion when he saw her, and while abusing the thieves and trying to kill her let her get away. She became a second edition of Bill Sykes's dog in more senses than one; she was a means of conviction and recognition, and she would neither be caught nor killed. No amount of food would tempt her down, but, like a feathered Cassandra, she sat on high and prophesied woe, which most assuredly came. Through her the man was taken, and is now enjoying penal servitude. As the thief and the receiver were leaving the dock, the latter soothed his wounded spirit by saying, "This comes of people saving pets."

Four-toed Dorkings, five-toed Hamburgs, crooked-combed

Cochins, eccentric chickens of every kind should now pass into food or market. "Well, but," says one, "they are such little things." Granted. Then it becomes a matter of calculation whether they will pay for the food they consume. If that is not likely, eat them. "But they are so small;" then make four do the duty of two. Eschew the curse of ordinary English cookery, the plain roast and boil, and make what some people call "a mess." Many who, in what we Hampshire people call "pig-killing time," when like "Romford Facey," "we live well," can enter into the merits of "liver and crow," or fried "griskin," or "lean meats," at other times eat veal and bacon, and never dream of frying these little chickens. They hate cookery. Well, let us teach them a little of it. It is of no use to try to fry them whole. Let them form part of a dish; but how to cut them up, they are all joints and bones. A very clever writer on cookery says, "If you do not please the eye, you will not please the palate." He is right. We dare say some of our readers know the feeling when reading of a terrible surgical operation, or an accident, or something of the sort, there is a shudder begins at the extremities, and runs chilling up to the head. We felt something of the sort, when in our poultry experiences we visited a kitchen to view the operation we are advising. Our evening's conversation had been pretty much in the style of our present writing, and our fair hostess, while listening to our instructions, constantly repeated to her "other moiety," "Now, mind you recollect, Frank." After breakfast the good lady left the room, and "signalled her consort," who directly asked to be excused, and followed, we fancied, rather reluctantly. We make it a rule to go away from loud voices, but we are attracted by a merry, cheery, and ringing laugh. We heard such, and after a time we went to it, and found an unhappy chicken on the board. It had suffered we know not how many incisions in the endeavour to carry out our instructions. The lady very wisely had given up the task to her husband, who after vainly endeavouring to cut crosswise through the breast gave an awful chop just as we entered and certainly divided it, but in such a style as justified his wife's laughter, and gave us the chilling shudder we were speaking of. We do not believe a husband ever likes to be laughed at by his wife, and, therefore, it was with something of vexation he said, "There, that looks tempting, certainly." His wife said something about being cut to pieces by a railway train, and to prevent a continuance, we volunteered again to describe the whole process, as follows:—First, draw the chicken, take a sharp knife and divide the merrythought in the centre, then cut from the point of the breastbone straight along towards the neck, keeping the edge of the knife against the bone that no meat remain on it. When it has reached the end of the breast let the knife keep along the bone till it reaches the joint of the wing, which must be divided. Detach the under part of the breast by cutting it from the bone with the point of the knife, and you will have that which is termed a "fillet." There is one, of course, on each side of the breast. Cut the legs off at the knuckle; then take off thigh and drumstick, which you will divide. You have now the side bones to remove. Then cut the carcass in half lengthways; divide the back just below the oyster-pieces, and with a broad heavy knife or chopper flatten both pieces. Try two or three little chickens fried in this way, with some thin slices of cherry-coloured bacon, and we promise you a good dish. Some good judges, who like flavour, fry a few aromatic herbs with them. Do not forget the neck, gizzard, liver,

heart, legs, and breastbones—they considerably help the gravy to serve with it. We have wandered till we must defer future remarks and advice.

### REARING POULTRY IN A CONFINED SPACE.

HAVING read the several papers upon "Poultry-keeping from a Commercial Point of View," and finding they have ceased, I beg to submit a few hints for the benefit of your readers, prompted by the perfectly theoretical style of those papers.

Before our friends go too deeply into the speculation, let us question the most reasonable plan for keeping poultry from a "truly commercial point of view," and I think we shall come to the conclusion that poultry may be kept with a much more commercial and business-like aspect in every home than is generally believed, and the enormous quantity of a million eggs per day would not have to be imported into this country. We need but to make it more universally known that poultry can be kept with profit in very limited spaces, and in London as well as the country, and show the public that by judicious care and feeding fowls will positively thrive well and lay just as many eggs as the very best yards in the country can boast of, and by so doing induce a thousand persons to keep fowls where only one person has hitherto done so. This, I maintain, is one way, and a certain, practical way, of keeping poultry from a commercial point of view, and by which the whole community would benefit.

There are very few houses in or out of London but what have tolerable-sized yards, or pieces of ground sometimes called gardens. If the sunny side of the smallest of these plots were parted off, and a neat but inexpensive dry roost and run made for only a few birds—that is to say, no more kept than would be required for eggs, and no cock allowed if there were only one house and run, as breeding would be of course quite out of character in such a case—further, if the family were taught to feed, but not fatten, the fowls thrice each day (and less if they did not pick up every grain thrown to them, one meal being saved from the house scraps properly cooked, and that meal prepared overnight, so that the scrap-meals might be all used up before any thing which had to be purchased were given to them), this, I say and maintain, would be the surest way to procure a poultry company upon a truly commercial system in every home, with but very limited liabilities and very limited expenses. I am sorry to say I have found numbers of persons commence keeping poultry and give up very quickly in disgust, declaring that each egg cost something like 1s.; but I am happy to be able to add, that I have prevented several from giving up who were about doing so. I always found the causes as nearly as possible alike—that the birds were not looked after often enough by the family themselves. They were left to servants to feed them, who threw down bowlful of food, which became trodden under foot and wasted. The fowls either became so fat that they seldom, if ever, laid an egg, or else they sickened; and as for cleaning, this seldom or never occurred until the filth accumulated to such an extent as to become a nuisance. As for dust, gravel, old mortar rubbish, the fine-ash siftings from the cinders—these sanitary additions were never thought of, and often not understood. Of course, if some of these people had an egg it was generally without a shell; an occasional sudden death occurred amongst the hens through over-feeding, and, of course, all helped to deter families from more generally keeping them. Then, again, with their feeding, the green meat was not attended to. To economise the greens, which every family can obtain more or less plentifully, the proper plan is to pull off the leafy portions from the stems or thick parts, and give the fowls as much as they will eat; the remainder, together with the stems and edible portions of the stumps, should be chopped up to about the size of peas, and mixed with their prepared scrap-meal. By scraps I mean refuse pieces of meat (after the bones have been well scraped, give them to the fowls to polish, which they will do most cleverly), every crumb of bread, and potato-peelings, which must be cooked. The meat, whether fat, skin, gistle, or lean, may be either raw or cooked, no matter which. The whole of these being mixed

will form their best meal, most nutritious, most economical, and most conducive to egg-producing; and if these materials should happen to mix a little too thin, add some barley meal, but this expense all must try to avoid. The consistence should be such as, when thrusting the hand in, the mixture will not moisten and stick to the fingers. All egg-shells and other shells should be burnt in the fire, and when the ashes are sifted and the refuse thrown to the fowls they will pick out every minute particle of shell. This will assist them in the formation of egg-shells, and materially help, with other limey particles which must be mixed in the dust, in keeping them in good condition.

There is a small point in this method which should not be overlooked—I mean the sifting of cinders. In every house there is a considerable quantity of ash made, and some coals make much more than others, but it is not in every house that you find a cinder-sifting box. If it is insisted on, as an important duty on the part of the servants, always to sift the cinders collected every morning when clearing out the fireplaces, to throw the dust to the fowls, for which they will show signs of thankfulness, and take back to the house the large cinders for use, a visible reduction in the coal account will be perceptible in many families, which must be placed to the credit of the fowls' account. By adopting such a practice a dust-bin will not be required; a refuse corner may, for the purpose of storing the manure for the flowers, if there is a garden; or if a yard, a corner is required also for broken crockery, &c., and for hiding the manure.

How often has the question been put, and answered by people themselves in the same breath, "My fowls used to do well; now they seem sickened, degenerate in size, weak in productive powers. Is it," they ask, "because the ground is tainted by them?" This, I assure my friends, is one of the principal answers to my queries why fowls should not thrive in large numbers. The earth becomes tainted by them; they sicken of their runs; they sicken amongst themselves, disease surely creeps in, and they droop and die; and poultry will not thrive well upon that plot for at least two years. It is proved beyond all doubt that no such a farm as M. Sora's or any other man's poultry establishment ever existed, or does now exist, where chickens are hatched by thousands and tens of thousands, and thousands of hens are kept for laying eggs in one or on one estate only; and the horse-feeding system was no greater ruse than any other part of the plan once set forth. My opinion of it was that the whole production was a mere idea which the promoter thought a novel one, and he would just startle the nations with it, and put it down as a *bonâ fide* affair in black and white. I should say he was most likely one of the members of the Society of Horse-eaters (Hippophagist), not very well pleased with his meal, so he entertained a new idea of disposing of the remnants of their feasts.

In conclusion, I must add that I believe the plan adopted in France for producing such large quantities is similar to the plan I have proposed to a certain extent—that there and in other countries greater numbers of separate families keep poultry; and that which tends to their success is, that as they find the poultry help them to live, they attend to them systematically; and those persons we call bigglers go round regularly and collect the eggs from them; these, again, frequently sell the eggs to a factor, who is the exporter. This I can fully believe is the truly great poultry principle adopted in France and other countries.

With regard to the accounts of the hatching and rearing of chickens by millions in Egypt by the Bermeans, I believe fully in those accounts, but we are not in full possession of all the facts in connection with their proceedings. I cannot believe any one, nor one hundred, farms ever reared chickens artificially in any such quantities; so that I satisfy myself, and I think many of your readers will do the same, by believing that as the hatching of them by millions cannot be disputed, we must conclude that numbers of farmers and families came to these "mamals," as they were termed, and purchased them, and brought them up as best they could with the means they had at their disposal. Their climate was pure, and in every way calculated to assist them in rearing their birds artificially. They were good

growers of grain, and no doubt paid great individual attention to their feeding.—OLD FOX.

[We have omitted all you wrote about the proposed Company. There is no need "thrice to slay the slain."]

#### PIGEON BREATHING WITH DIFFICULTY.

FIRSTLY. Spanish liquorice dissolved in their drinking water I have found to cure cage birds, and no doubt it would assist the Tumbler cock.

Secondly. I had a red mottled Air-Tumbler cock which was taken very ill last year, being affected with a sort of asthma and sore throat. I gave him pills containing 1 grain calomel and 1-12th of a grain tartar emetic—one daily for two or three days—after which boluses of cod-liver oil and flour, and he speedily recovered.

Lastly. I read lately in the German poultry papers that bacon cut in small worm-like shreds and rolled in antimony was a sure cure for such diseases in chickens, no water to be given for three hours afterwards.

The above is all the information I can give; it is only necessary for me to say that antimony is a poison, and I believe Canaries have died from drinking water in which 3 grains were dissolved in a quart of the water.—B. P. BRENT.

#### THE DERBY CANARY AND ORNITHOLOGICAL SOCIETY.

We have been favoured with a copy of the "Handbook of the Rules and Regulations of the Derby Canary and Ornithological Society, for Promoting Improvement in the Breeds of Canaries and other Fancy Cage Birds," and which also contains the standard properties by which the choice breeds of Canaries and Mule birds are there judged.

Mr. G. J. Barnesby, of Abbey Street, Derby, in his preface gives a cheering account of the rise and progress of this Society, which appears to be now in a flourishing state. The book contains a long list of rules and regulations, forty-one in number; but as Rule 8 declares, that "No person is admitted as a member of this Society unless residing in the county or borough of Derby," these rules can have little interest for the general reader. We can only express a regret at this exclusiveness in these days of railroads and the general diffusion of the Canary fancy. We cannot help expressing a regret that the Derby committee should consider it necessary to be so strict with their members, since the London Fancy Canary Club have found it obligatory to go with the times, and adopt a more liberal code.

The standard of properties, which is of much more interest to the general breeder, is on the whole good; yet the arrangement of the points, as 1, 2, or 3, is not in accordance with the value of these points as set forth in their accompanying explanation.

The properties for Belgian Canaries are exclusively for the Hooped or Bowed fancy, a variety which strikes the novice by its ugliness; indeed, this fancy, like many others, is one of cultivation. We do not perceive the necessity of distinct classes for Marked, or Ticked, and Variegated Belgians. Would it not be better to have one standard for the best-marked Pied Belgians? It must also be regretted that no class or standard of properties is given for that magnificent breed the Erect Belgian or, as some call them, Dutch birds. We think the same may be said of dividing the Marked and Variegated Norwich birds as of the Belgians, but we conclude these are local fancies and distinctions not recognised by fanciers in other parts, though we have seen the same division of colour at other shows, but could not regard it with favour.

The rules for London Fancy birds are the same as those of the London Club, and they will do well to adhere to Rules 8 and 9, "Legs for blackness," "Flue for blackness." The points for Lizards are well given. The Copy or Crested Belgians have, as stated, "considerable grace." Mongrels we have no liking for, they are never satisfactory to the true fancier, though Cinnamon, Grass Green, and regular Pies are often very handsome and worthy of more attention.

We think Goldfinch Mules should be divided into Clear

birds and Pied, the one valued for their near resemblance to the Canary, the other for the regularity of their marking. Linnet Mules are also noticed, but other mules and sundry other breeds are not, we gather from a concluding note, because "they do not appear to find much favour" in Derby.

This Society holds a yearly exhibition, but it seems to be confined to the town and county of Derby.

"No appeals from the decisions of the judges shall be entertained upon any grounds whatever."

Prizes are also awarded for other British and Foreign birds.

The book concludes with a few good hints, but we cannot quite coincide with the last, that cats are not to be trusted; we can only say for ours that we can trust them, and though constantly among the birds they have never betrayed their trust. They are valuable in destroying mice, and also in keeping off stray cats which have not received a good education. We hope that this Society will take a more liberal view of the fancy generally and relax a few of their stringent laws.

#### REGICIDE AMONG BEES—HIVES DESERTED.

SINCE I last wrote in reference to bees killing queens of other hives, I have met with several instances of it, which I will relate.

The first was a hive to which some bees were presented that were benumbed with cold, they went in readily, but next morning the queen was thrown out, not dead but quite lively and able to fly. The commotion shewed distinctly to which hive she belonged, and when returned she was gladly received. While holding the hive in my hands in order to witness the result, I could distinctly see the motions of the bees, and while most of them paid homage to her, who was by this time a mother, there was one bee more restless than the rest which showed signs of great uneasiness, and it at one moment darted at her and would have killed her had I not prevented it. I am pretty certain that it was one of the bees I had presented to the hive the evening before.

The second case was that of a stock which lost its queen under the following circumstances. While manipulating a hive and taking some bees from it to add to a weak Ligurian colony, I saw two of the bees enter another hive, and in half an hour these two bees and the queen were thrown out dead.

The third case was similar to one which I mentioned some time since, and was that of a strong black hive from which I took some bees to add to another weak artificial hive of Ligurians. Although I saw the queen when the crown-board was removed, yet ere I laid it down she had disappeared, and after examining every comb I failed to find her. The day was warm, and by reason of the delay the smell was attracting robbers. At length I found her in a corner of the hive surrounded by a few bees. At the moment I was about to seize her a strange bee darted furiously at her when I had just caught her, and so intent was it on getting at her that it followed my hand, attempted an entrance, and nearly effected it, having hold of the queen by the wing, and actually stung my hand instead of her. I would, therefore, caution all apiarians while manipulating with bees which have a queen to try and prevent their entering other hives, as I am perfectly satisfied that strange bees will kill queens. Still while advancing this doctrine, I do not deny the fact of regicidal attacks, although I have never witnessed them; but this I know, that I have seen queens imprisoned by their own subjects when strange bees were admitted into their hives.

On the 5th of April, I noticed a commotion at one of my Ligurian hives, and found the queen lying before the hive; I raised her and placed her at the mouth, when she entered reluctantly, and in a few seconds I was astonished at the great number of bees entering; they had deserted and were returning. I thought the cause was their being few in numbers; and knowing the value of a Ligurian queen I did not wish to lose her, I therefore took about 5000 bees from a strong swarm of blacks and added to them. The Sunday following being a fine day they took wing again, and I was just in time to see the queen depart, but was too late to catch her, although she was the last to come out. They

entered a hive at some distance and were all killed. There were upwards of 15 lbs. of honey, and all in new combs. The only remarkable feature was the confused manner in which the eggs were deposited in the cells, there being from two to four in each cell.

Another case of partial desertion was a Ligurian hive which was strengthened with black bees four weeks previously. Sunday the 16th of April being another fine day, the whole of the Ligurians fled and left their fertile queen with her black subjects. The Ligurians tried to enter a very strong colony of black bees a quarter of a mile off, but were all killed. It appears to me that whenever the bees are unable to meet the demands of the queen they fly off, as I never knew a strong colony desert its hive, whilst I have seen a weak one with a barren queen remain till the bees had dwindled away and only the queen was left; but whether this partial desertion was from that cause or for the purpose of robbing I know not, but, perhaps, Mr. Woodbury will say to what extent the Ligurians are inclined to rob or change hives, as I remember his mentioning something of the kind. By so doing he will favour more than—A LANARKSHIRE BEE-KEEPER.

[The occurrence referred to by my Lanarkshire contemporary took place on the 2nd of April, 1863, and was related by me in "our Journal" of the 12th of the following month (May), in that year. It consisted of the entire desertion of the bees of a Ligurian stock, attracted by what the Germans call the "swarm-tune," set up by a very powerful colony of black bees when released from confinement after a long journey, and placed in too close proximity to the Ligurians. This desertion was, however, speedily and completely remedied by causing the two stocks to change places. It is true that the Italians share the pilfering propensity, at least equally with their dark brethren, but I have never found them at all prone to desert their hives. In fact, most of the circumstances above related are quite unparalleled in my experience, and I trust my Lanarkshire friend will forgive me for hinting, that they seem to me almost to labour the suspicion of what may be termed over-manipulation on his part. I hope ere long to have the opportunity of redeeming my promise of considering what has been advanced by others on the subject of regicide among bees.—A DEVONSHIRE BEE-KEEPER.]

### MAKING AN ARTIFICIAL SWARM.

I WISH to make an artificial swarm from a common straw stock hive which is very full of bees, many clustered on the outside. Under these circumstances I would perform the operation at once, but for the condition laid down by Mr. Woodbury, that drones should have made their appearance prior to the swarm being driven.

May I ask, if it is intended that it is only advisable that there should be drones in the swarm, or whether it is absolutely essential? After the swarm shall have been driven, would it be a favourable opportunity to introduce a fertile Ligurian queen, and can you tell me where I can purchase one?

I weighed my six stocks on the 4th ult., the weight was 126 lbs. gross, or about 90 lbs. for the contents of the hives. The loss in weight since the 3rd of December, 1864, a period of four months, averaged only 6½ lbs. per hive.—M. S.

[The presence of drones in an artificial swarm is not essential to its success, but it is absolutely necessary for the fecundation of the young queen that drones should exist in considerable numbers either in the parent stock or in some of the neighbouring colonies within, say, a fortnight after the operation. There would, we think, be a better chance of success if the introduction of a Ligurian queen were delayed two or three days after the formation of the swarm, but we do not know where you can procure one.]

EARLY SWARMS.—A fine top swarm of healthy bees was thrown off a last season's swarm at Tollamill, Inverkeithing, on the 16th of April. It belonged to Mr. Henry Marr of that place. A hive at Westhall Gardens, Oyne, threw off a fine swarm on Saturday, April 22nd.—(Banffshire Journal.)

### VERY WEAK STOCKS.

Two hives, Nos. 1 and 9 are both extremely weak. From No. 9 are thrown out numbers of dead drones, and no increase of the other bees. Would you unite them? I do not think there is half a pint of bees in either.

[No. 9 has probably a drone-breeding queen, which should be got rid of before uniting. If this cannot be done we should dispose of the drone-breeder and the remaining bees together by means of sulphur, appropriating the combs and their contents to such purpose as they may prove best adapted for. No. 1 may in this case be best restored to prosperity by the addition of a small swarm.]

### OUR LETTER BOX.

POULTRY SHOWS.—"A Hamburg Shower" complains that he did not know of the Wharfedale Exhibition, or he would certainly have exhibited there. This is not the first letter upon such omissions; but if Committees will not advertise in our columns, and send the necessary statements, we cannot save our readers from such disappointments.

DUCKS (*Constant Reader, Nantwich*).—If by saying the "Ducks per<sup>ca</sup> in a large pond," you mean that they sleep there at night, it will do them no harm.

GOOSE EGGS UNFERTILE (*W. C.*).—We do not know how you account for the three fertile eggs, but your gardener is right. If the tub is deep it may answer the purpose.

VARIOUS (*Old Subscriber*).—Your hens may sit in the cellars, but the chickens must be removed to a drier and better atmosphere directly they are hatched. Hens become egg-bound from a fevered state of body. The remedy is to dip a wing feather in oil, and to lubricate the passage with it. It affords immediate relief. The symptoms are—the hen walks with her tail on the ground. Many Bantams are uncertain breeders; the eggs you mention are not impregnated. We cannot believe any one would purposely spoil the eggs he sells for sitting. Leaving higher considerations out of the question, it would be against his interests. Game cocks' combs require no preparation.

REARING YOUNG PHEASANTS (*Notice*).—You must put your young Pheasants on a dry and dusty spot, where they will have plenty of sun. Feed them on curd, chopped egg, bread and milk, cooked meat, chopped fine. Buy "Pheasants and Pheasantries," by Bailly, 113, Mount Street. It costs by post, 1s. 1d.

SWELLING IN HEN'S ABDOMEN (*F. G.*).—If the swelling in question is fat, the frequent doses of castor oil will remove it. If it is not, it is a fatal case, and a mere question of time. It often results from over-feeding, especially with meat. If it does not decrease, we advise you to kill her. You will find the hard substance made up of cheesy stuff, such as would be produced by a mixture of white and yolk of eggs. Let her diet be barley-meal and mashed potatoes, with plenty of green food, especially lettuce leaves.

SPANISH HENS WITH BREAST SWELLINGS (*B. B.*).—The swelling is a dropping of the crop. It is generally caused by a rupture or a relaxation of the skin; at other times by a fevered state of body, which causes intense thirst, and they drink till the crop is unduly filled and distended. The latter case can be cured by confining the birds, and giving them a small allowance of water; if mixed with vinegar or wormwood so much the better. In the former case it is incurable. The hen will go on laying, but you must make up your mind to submit to the eyesore, or the pendant in front.

SPANISH HENS BALD (*H. S. C.*).—Rub the bare places with sulphur ointment. All this is sometimes the work of one hen; if that be the case, remove her. The knife is not necessary. The feathers will all grow again speedily.

GIDDINESS IN A PIGEON (*J. L. J.*).—Your Pigeon seems to have met with rather rough usage. The twisting round of the head would seem to indicate that the brain was affected; and not being able to fly may arise from the same cause or from injury to the back. If the scalp is much torn it may be softened by bathing with warm water. The edges may then be drawn together by a needle and thread, and the wound anointed with unsalted butter or lard. Place her in a quiet pen by herself; give a pill containing one grain calomel, followed by a teaspoonful of castor oil: avoid hempseed or stimulating seeds; and put down her throat daily three or four pieces of mortar about the size of peas. If the twisting of the head increases repeat the calomel and oil, and pull out the tail; this in growing will draw the blood from the head.—B. P. BRENT.

RABBITS (*C. S.*).—Ivy leaves will not injure them.

ERRATUM.—In the article at p. 352, "Hives with Entrances at the Top," the explanatory line under the woodcut should read—"A Passage sunk in the top, permitting entrance to the stock-hive."

### LONDON MARKETS.—MAY 8.

#### POULTRY.

Our supply remains very small, and, but for the unprecedentedly small demand of the present season, prices would be very high.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 65.9°, and its night temperature 43.1°. The greatest heat was 89° on the 22nd, 1847; and the lowest cold, 30°, on the 18th and 19th, 1854; 20th, 1853; and 19th and 20th, 1856. The greatest fall of rain was 0.58 inch.

MISCELLANEOUS NOTES MADE IN HOLLAND AND BELGIUM.

(Concluded from page 357.)

ALEY has maintained that every defect has its compensation, and certainly deafness had one on the 12th of April, for there were two Frenchmen in the carriage with us on that day who never ceased chattering nonsense during the two hours of travelling between Brussels and Ghent. And, then, what clever fellows have been deaf!—Kitto and Sir Joshua Reynolds among the past, and Professor Naudin among the living. It is almost

worth being deaf to be represented as Reynolds was at the Royal Academy last year with his trumpet to his ear listening to the reconciliations of the dying Gainsborough. Then the various uses that the hearing-trumpet can be applied to! Among others, we remember, an old lady who delivered seeds into drills through its small end. So even deafness may be connected with horticulture, and this brought us to Ghent, for we had long desired to make notes on its two most celebrated nurseries—Van Houtte's and Verschaffelt's.

M. Van Houtte is one of the men of mark of our generation—he has led in more than one successful struggle for freedom; for twenty years has he lectured gratuitously on horticulture to the young gardeners of Belgium, and during those years nearly 88,000 of them have been his auditors. The government wisely facilitate their resort to his lectures, for having the railways under its own control the government gives a free pass over them. He must be a capital lecturer, for he is full of knowledge, is a man of merriment, and one of the best talkers in Belgium. Besides, he is the editor of the "Flore des Serres," one of the best of floricultural journals. The illustrations of the journal are entirely prepared within his garden's enclosure. We saw the artist engaged on the original drawing; the lithographers and the colourists at work, and Van Houtte himself supervising all, and answering the most important of the letters received. This is no light task, for we saw the letter register, in which between January 1st and April 13th were noted and epitomised 2394 letters, which, deducting the Sundays, is more than 26 *per diem*. These, of course, for the most part enclosed orders for plants, and the extent of the business may be estimated from there being fourteen men and women at work in the packing-house, and we counted fifty packages ready for the van which had arrived to convey them to the railway station.

To meet such a demand there are thirty-nine propagating-houses, each about 100 feet long and 18 feet wide. To supply these and the hardy out-door plants there are

eighty tanks distributed about the garden; for the soil is very sandy, and requires a large supply of water, and this is pumped up chiefly from the Scheldt by an engine working all day. This engine does other work, grinds corn, cuts laths for the shades, and other wood, &c.

The nursery includes thirty-eight acres, and, of all grades and employments, two hundred workmen have to be paid every Saturday. We estimated that there were two acres of Hyacinths in bloom and five acres of pyramidal Pear trees. Beside the buildings and offices we have enumerated, there is a large seed shop, potting-houses, carpenter's shop, and a boiler-maker's forge, with engineers and carpenters constantly employed; and a pot-store, with one man entirely occupied by cleaning and sorting the pots.

All the houses are heated by one boiler on Weeks's system, but there are two additional boilers provided, to be ready against accident, and as there is a gas-work also on the premises, our readers will appreciate what a microcosm it is of all that pertains to a nursery.

It would far exceed our limits to enter into minute details, but we may state one more fact to aid to an estimate of the extent of the business—one house 216 feet long and two other houses each 100 feet long are filled with Camellias alone.

Among the tree Ferns are some noble specimens, and it may prove a useful suggestion to some of our readers to notice that each Fern which had grown so tall as to be ready to thrust its head through the glass roof at once had the ground cut from beneath its feet—that is, a well was sunk, bricked round, and the tub in which the Fern was growing lowered into it.

We have mentioned that the engine cuts the wood for the shades. These are formed of half-inch square laths, and these are fastened one-third of an inch apart to ropes. The ropes are a foot apart, and these, of course, are the whole length of the shade. It forms a kind of Venetian blind, rolling up, and is far more durable than any kind of cloth. Each shade is 7 feet wide. The spaces between the laths admit a subdued light.

We lingered for hours in the proprietor's study, and could fill pages with notes of "Excursions among Van Houtte's books and pictures of plants," but we must only pause to remark that, as usual among the Belgian lovers of botany, there was more than one memorial of Dodoens; and well does he merit their veneration, for he was not only the botanist of Belgium but of the sixteenth century. His portrait, "Etat 35," is prefixed to the "Herbal" "first set fourth in the Douteche or Almaigne tongue by that learned D. Rembert Dodoens, Physitian to the Emperour; and nowe first translated out of the French into English by Henry Lyte Esquier. At London by me Gerard Dewes, dwelling in Pawles Church-yard at the signe of the Swanne, 1578." There is a better portrait and a full memoir of Dodoens in the first volume of Morren's "Belgique Horticole." Even in the door of one of M. Verschaffelt's hothouses was a portrait of Dodoens in stained glass.

This leads to our notes on the second great nursery of

Ghent, and indeed of Belgium—but we will not plunge among its vegetable treasures at once, but record collectively our obligations to all the Dutch and Belgian cultivators of plants with whom we held conference, for their uniform courtesy. M. Verschaffelt is a representative man—genial, replete with information, communicative, and talking English fluently, with no more of a foreign accent than is sufficient to render it racy.

His nursery is scarcely less extensive and his business scarcely less large than M. Van Houtte's. We counted thirty propagating-houses. Of Camellias 28,000 are grafted annually, besides the thousands raised from cuttings. M. Verschaffelt exhibits far and near at the continental shows, and the possession of 1000 medals, of which we saw 250, are unmistakable evidences of the richness of his stock, and the skill devoted successfully to its cultivation. In every department there was a neatness in details, and a healthiness without exception, which was very striking.

In noticing at page 343, Palms used as Room Plants, and to the propagation of which M. Verschaffelt addresses much attention, we omitted to particularise *Latania rubra*. It is a most agreeable addition to their groups, its red leaves in some measure compensating for the absence of flowers.

Among the most striking of profusely-flowering climbers is *Clerodendron Thomsonæ*. Two years since, M. Verschaffelt placed a plant of it at each end of a house, 45 feet long, and when we saw them in April, trained to a wire along the apex of the roof, they had met and presented an uninterrupted wreath of 45 feet long densely covered with the plants' lovely white, crimson-tipped flowers. It was a natural beauty not to be forgotten.

The Ferns throughout were gratifying specimens of careful and able cultivation, whether we turned our attention to the liliputian species, or to the Brobdignag specimens of such genera as *Cyathea*. Many of them had resisted all attempts to induce them to grow vigorously—and this well deserves attention—until they were grown in a house sunk 5 feet below the surface. The stems of the tree Ferns never matured when grown in a house, the floor of which was on the ground level. In the house sunk below that level the natural moisture of the air sufficed to induce the desired maturity, and the descent of rootlets in a kind of network on the exterior is very remarkable. Tree Ferns which had refused to thrive have in this house made rapid growth, though only removed to it in last November. Even *Cyathea Smithii* is there growing vigorously. The pots for even the largest specimens are only 15 and 20 inches in diameter.

With that note we must conclude, and hasten back to

"This other Eden, demi-Paradise;  
This fortress, built by Nature for herself."

Thus John of Ghent, or Gaunt, as we English persist in calling him, described England, as Shakespere tells us, and, let us add, if ever business, or even sterner need, take us again to Belgium, we shall readily adopt old Gaunt's advice, for we shall remember how much of gratification we there enjoyed, and again

"Call it a travel that we take for pleasure."  
certain of not being disappointed—G.

## ROCK PLANTS.

Success in the cultivation of rock plants depends in a great measure on providing them with a suitable soil and position. No hollow space should exist beneath them; but it is a very common practice to form the rockwork and fill in the crevices with soil, and the soil becoming too dry in summer the plants perish in consequence of their not being deeply rooted, for the hollow space beneath prevents this being the case. The rockwork, if properly formed, will have the lower and inner parts efficiently drained by filling up, as the work proceeds, with rubble or materials that will allow of the water escaping, without leaving any vacancy that will interfere with the well-being of the plants. In rocks that are carried to a great height the inner parts need not be composed of substances that will allow of the superfluous water escaping in that direction, but may consist of any kind of materials. The portion immediately below the rocks, however, should be loose and open, in order that water may drain from the surface, and should communicate with a

part laid lower and filled with rougher materials so as to carry off the water. I have known a large mound formed and covered with rock so as to have a fine effect, but though several times planted it still remained barren, except the upper parts where the plants were more healthy. This mound proved to have been formed of what was little better than a mass of clay and mud, water would not percolate through it, and this so deluged the lower parts of the rockwork that the plants nearly all perished in winter, especially the more choice kinds, which were planted at the lower parts so as to be more under the eye.

Rocks, then, should be so formed that the lower parts may not be deluged with water, for though many rock plants like cool situations and moisture they will never thrive grown as if in a bog. The majority of Alpines are found on moist soil on rock, the under strata being rock or gravel, through which the surface water finds its way. Whether plants delight in moisture, sunshine, or shade, the draining away of water by the under strata is necessary to their existence, for none flourish in a wet and sour soil except aquatics. With plants peculiarly adapted for growing on dry rocks, moisture if at all excessive in winter is their certain destruction, and not less detrimental to their well-being is planting them in unsuitable positions. It is in a great measure owing to the bad construction of rockwork that the majority of Alpines are grown in pots. In forming rockwork not only should effect be studied, but the health of the plants to be grown upon it. It should be formed so as to permit of superfluous water being drained away, and there should be ledges and crevices between the surface stones which may be filled with soil.

As regards soil the majority of Alpines do well in a compost of turfy yellow, or hazel, loam, the top spit taken from a pasture and laid in a heap for twelve months, and turned over occasionally. To this may be added one-third of leaf mould, or where it can be had sandy peat would be preferable because more lasting. Some require peat soil alone, or mixed with a smaller proportion of loam; others a free open soil, which may be obtained by mixing small pieces of stone with the soil, sandstone being best; but brick rubbish will do if stone cannot be had.

The crevices and ledges being furnished with soil of the suitable kind (but without covering the stones to any great extent, and leaving some quite naked, otherwise the natural rock-like appearance will be destroyed), planting may be proceeded with. In doing so take advantage of a hollow in the upper part of a stone to introduce soil and a plant of a kind that will cover it in time. Guard against crowding; leave room for all the plants to grow into large patches, unless, indeed, they are not of a spreading nature, when they may be planted much more closely, but never so as to smother the non-spreading, but all so that they can grow and unfold their beauties without requiring much and frequent attention in order to keep them within bounds. In planting bear in mind that rockwork is expected to be interesting not at one particular period, but at all seasons, and do not put all the spring-blooming species in one place, and the summer-blooming in another, nor should those of which the merit mainly consists in their foliage be all collected in one place, but plant for effect at all seasons. In a word, mass them as you would bedding plants, and they will then form a fine feature in the distance, being beds of white, blue, red, and yellow, interspersed with green and rocky crags. It is astonishing what splendid masses some Alpines, usually so insignificant in pots, make when planted in nooks and corners of rockwork where, small as they are, they often become too large for the places assigned them. No one who has not seen them in masses in their native wilds, or in large clumps on rockwork, can form an idea of their beauty from the cultivation of them in pots or small patches.

Whilst providing for rendering the rockwork effective at a distance, these masses should not be seen all at once when close at hand. Another great charm of rockwork is to find some plant where no one would think of looking for it. Some of the more diminutive species should be apparently hidden by the masses of the spreading kinds, and though not productive of effect at a distance, will be very interesting at a near view. Alpines are best planted in spring, but those which are evergreen may be successfully removed after flowering. It is advisable to have them established in pots;

they can then be planted out at any time, either that, or transplanting with a ball, being necessary to the success of many kinds. A few will succeed without this care, but the majority require attention in planting and watering until established.

After blooming the dead flower-stems and those seeding should be cut away, the clumps or patches reduced if too large, thinned out, and weeded. In spring a little fresh soil may be placed around those which from want of soil do not spread so much as desired. The whole should be gone over twice a-year—in spring to add a little fresh soil to such as require it, to see that none are suffering from want of room, and to replace the dead with fresh plants; and again in autumn to remove all decayed foliage and give the whole a tidy appearance. At other times rock plants require but little attention beyond an occasional weeding in summer, watering in dry weather, and now and then a little regulation to prevent those of less luxuriant growth being smothered by their more vigorous neighbours. Want of attention, however, to these simple matters will seriously affect them in time, and a goodly selection will dwindle down to a very few kinds, and these, the commoner and more hardy. Rock plants, are a very numerous class; and to give an account of all that we have at present in cultivation would be extremely tedious. I can only, therefore, note on a future occasion some of the more conspicuous.—G. ABBEY.

#### IMPORTANCE OF AN ABUNDANT WATER SUPPLY.

We cannot command the sun—the fire queen; but water we can supply. We can, in some measure, obtain artificial heat. I fancy that in time we shall geothermalise our gardens with hot-water pipes, and also lay down tramways for the easier transport of water. When we get an excess of sun, vegetation languishes, and when we have an excess of rain in a sunless summer, for want of heat and an equivalent evaporation, plants in our gardens put on sere and yellow leaves. Our gardeners often fail, and are blamed for faults not their own. How often do we see in large gardens only one pump, and that one in an inconvenient place to make the most of it.

Three of the most necessary things to look to, in selecting ground for a garden, are the capacity for free drainage, access to the sun's rays, and an adequate supply of water. A garden should be flat, and in the case of one pump, tramways should be laid down, and the water should be conveyed by water-carts drawn by a donkey or by a man. In either case much water may be conveyed with proportionately little effort. There is, however, another way still easier. Water-tanks on raised brickwork may be established near the pump. By a forcing-pump the water from the pump may be lifted into the tanks, hose of sufficient length to reach all parts of the garden, may be attached to the tanks and without further effort, by turning the screw, a man may "stand at ease," and water copiously the languishing plants. At a large establishment near here this is done. By machinery turned by a horse the water is forced up to the reservoir on the top of the stables, which are above the garden. It descends thence by a pipe, to which a hose is attached. I have myself watered with it the bedding plants effectually on a broiling summer's day. Nor is water less essential for culinary plants in such a summer as the last. There is, however, one plant to which I am more attached than to any other, which needs for the cleansing of its foliage, and also for other purposes, a deal of water in a burning summer—namely, the Rose.

The sun's power of exhausting moisture is beyond conception. Strong lands for a while supply the plant with moisture by capillary attraction; but as soon as the moisture is exhausted the sun bakes the land into a concrete, and burns up the rootlets. The plant, of course, will do no more that year, even if it do not die. Nor is this the case with Roses only. Were Beans and Peas invested with a voice, they would tell you of the necessity last summer for rain, or "*aqua pumpaginis*." What multitudes of things are burned up, or so checked before rain comes, that they are spoiled every torrid summer.

To show how much we owe to Providence for the supply

of rain, I copied (when I wrote this article, some months back), the following from the *Evening Mail*:—

"The deficiency of rainfall." "Few people have an adequate idea of what is really implied, when the Registrar-General reports, that the deficiency of rainfall at Greenwich in the last two years has amounted to nearly 14 inches. If that is an average instance, respecting deficiency in the country generally, then the quantity of rain in England and Wales in 1863 and 1864, has been below the usual quantity by at least 52,000,000 tons of weight of water, or 500,000,000 tons per week."

In my small place I have three pumps. Nothing that I care for ever lacks water. I love a dry summer and a West Indian sun. As the sun burns so I pump. Owing to this, last summer I had fruits in perfection, and a daily exhibition of Roses. The earth was as hot as a frying-pan. For lack of water no doubt many people's Roses suffered in their roots, and have been finished up by zero; but I have lost hardly any, and from summer-watering and winter-strawing I never had them in such splendid condition as they are now. The same may be said of the Strawberry plants and other things, all of which were kept well supplied with water.

It is to be hoped that proprietors of gardens, especially of large ones, will place at the head gardener's disposal sufficient water power. Without this, in such a summer as the last, he must be signally defeated. When the gardeners of England read this attempt to aid them, I have no doubt they will cry loudly, "hear, hear!"—W. F. RADCLIFFE, *Tarrant Rushton, Blandford.*

#### FRUIT TREES IN CULTIVATED AND OTHER GROUND.

Some time ago Mr. Fish called attention to the fact that fruit trees are occasionally to be met with in a highly productive condition, although, so far as tillage of the ground is concerned, their roots are sealed up from the external air. Examples of this often present themselves, and now and then cases of an extreme character appear. It is not unusual to see a Pear tree occupying, perhaps, 400 or 500 square feet of wall, although its roots are under a stone or brick pavement, or, it may be, a macadamised road, and yet the health and fruit-bearing properties of the tree are all that can be desired. And why should it not be so? Nature presents us with examples of other kinds: an old Oak, around whose venerable stem the children of several generations may have gathered acorns, continues to put forth green leaves, and to bear its accustomed crop, with no more breaking up of the soil than that which arises from the action of frost; and probably Nature requires no more—at all events we see her work effectually performed without our assistance in the case of the Oak. The Hawthorn, Yew, and, in fact, timber trees of all kinds, carry on their growth in a manner which we cannot well improve upon—and all without the spade. Hence it becomes necessary to pause ere we too confidently affirm its utility in the case of fruit trees that have attained a fair bearing size. At the same time there are some considerations which ought to have due weight in arriving at a decision in their case.

In general great rapidity of growth is rarely wanted in any fruit tree except it be the Vine, or when, in some special case, a tree is wanted to occupy a given space as quickly as possible. More generally, however, a moderate growth and firm well-ripened shoots are desirable, and to obtain the latter, deep rich soil is, perhaps, not the best medium, unless it should happen that the summer, more especially the latter part of it, be dry and warm, so as to ripen instead of prolonging the growth of the young shoots. Mr. Fish justly observes, that ground having a hard firm surface is somewhat warmer than it would be if it had the loose texture given it by tillage, and we may give the warmer and drier medium the credit of ripening instead of prolonging the growth of whatever it may be cropped with. Now, in the case of fruit trees, early growth and its proper ripening are of the greatest importance, while with kitchen-garden crops, especially of certain kinds, the reverse state of things is wanted; and to combine the culture of the two, as is often done, must, of course, entail a somewhat intermediate course,

not the best possible for each individually, but unquestionably the best for the two united. Let us see how these considerations affect the class of fruits whose cultivation involves most uncertainty, and, commencing with the Peach, let us examine the general conditions under which it is grown.

I believe in a former article I have stated my belief that the Peach thrives best in a soil containing more than the average amount of saline matter, and in this view I was confirmed by a correspondent who had seen the rapid growth the trees make in South America, where the ground was almost crusted with salt. There is also some reason to believe that the soil of the districts in Australia where the Peach thrives so luxuriantly, is also more or less impregnated with salt, and in our own country some of the best Peach trees that I know of are to be found near the coast, where the influences of the sea air as well as the salt spray have given the required seasoning to the soil and atmosphere. In inland districts the prosperity or otherwise of the trees may also be in some measure attributed to the presence or absence of salt in the composition of the soil of the district in which they are grown, coupled, of course, with other favourable circumstances. This, however, is a digression from the object in view, which was to determine whether a surface rendered open and porous by tillage or one that was firm and hard was the better medium for the roots. On this point the evidence is naturally conflicting, as there are comparatively few Peach-borders which are not dug more or less, and the question of the utility of digging is as often answered in the negative as in the affirmative, by the trees not prospering in a cultivated border; nevertheless there are a few cases in which Peach trees on a border in a great measure exempt from cultivation thrive and produce good crops, and one of these cases of an extreme character may be adduced in support of the plan of non-cultivation.

About thirty years ago a gentleman who had a very good wall of Peach trees, which up to that time had produced good crops, and were by good management kept in tolerable health, thinking they showed signs of declining vigour, conceived that it arose from the border being cropped. The border, 10 or 12 feet wide, was not heavily cropped with early Peas, &c., as is too often the case, but was devoted to the growth of the best herbaceous plants, with now and then some from the greenhouse intermixed with them in summer. Of course, a certain amount of digging was performed in winter, and the gentleman thought there was an apparent falling off in the health of the trees, and as he was a keen horticulturist, he conceived the idea of having the flowers all removed, and the border covered with turf, which was done much to the chagrin of many who admired the choice collection of plants carefully arranged on that border of some 500 feet in length, as well as on one on the opposite side of a ten-foot-wide walk. However the turfing was accomplished, and the spade laid aside, and I was told with good result. Unfortunately, my acquaintance with the place ceased soon after the change alluded to, but from the evidence of a friend the trees prospered for several years afterwards. This, no doubt, is an unusual case, but it confirms Mr. Fish's views, in so far that tillage is not always an essential feature in the culture of healthy trees. I may add, that although the place in question was in the far north, and on an elevated position, it was nevertheless a dry one, a sandstone shatter forming the subsoil, with a great depth of sandstone underneath. Doubtless the free percolation of water through the soil had much to do with hastening the ripening of the wood. I believe that other plants not usually met with so far north withstood the winter very well in that garden, and one of the largest plants of Hydrangea I ever saw was in it, and some standard Figs had stood some years in a sheltered corner, but I do not think that they bore much, unless it was in the hot summer of 1826. To add to the favourable position of the Peach trees, the wall was flued, and for a month or more in spring, and the like time in autumn, fires were kept on to protect the blossom, and ripen the wood. These advantages, however, would seem to be wanted to counterbalance the bleakness of a situation at least 600 feet above the sea, and only twenty miles from it, in a latitude north of Carlisle. Here, then, the trees thrived with a cultivated border; they also prospered when the spade was laid aside, and

though their being either better or worse afterwards, was doubtless in some degree dependant on the seasons, and other circumstances, yet the fact of their doing well when grown with their roots under the turf is a point worth noticing, and in its way an unusual state of things. Now, let us turn to another case, and see how trees of other kinds thrive in a soil unmoved by the spade, or other cultural implement.

In districts where the hardy fruits are grown extensively there are various modes of managing orchards; but the most general one is to plant the trees on ground that has either been subjected to tillage or been dug or trenched for the express purpose; and usually tillage is continued for a number of years, depending, of course, on the character of the under crop, which may either be bush fruit, vegetables, or farming crops; but as the trees attain a greater size, tillage is given up, the bush fruit removed by degrees, and the ground sown with grass seeds. The last operation, I may remark, is done earlier in a Cherry orchard than where other fruits are under cultivation, as experience has proved the Cherry to suffer more from the spade than any other tree. Cherry trees on grass very often attain a patriarchal age; I believe there are instances of trees upwards of two hundred years old, though such ancient specimens are long past their best. Apple and Pear trees also thrive well on grass, and some very old specimens are now and then met with in such a position. At no great distance from where I write are some venerable trees of a bygone age. Their boles are in no place of less circumference than 4 feet; and though every winter destroys, or partly destroys, one or two of these ancient trees, those remaining produce very fair fruit in favourable seasons, and put forth leaves with the vigour of younger members of the vegetable community. They have existed on a piece of pasture land from a time beyond the recollection of the oldest person in the neighbourhood. Returning, however, to the case of Cherries, there is little doubt but that they benefit more by being let alone than when their roots are mutilated by the spade or plough, as is done in some cases.

It would be idle to point out instances in which trees have maintained a healthy and fruit-bearing condition for so many years with a turfed surface, and beneath an impenetrable roadway the roots of good fruit-bearing trees likewise very often exist. There is one thing, however, that ought always to be borne in mind—good tillage in the first instance promotes rapid growth, and therefore it is advisable to bestow some pains in the first formation of a plantation when the trees to be planted are required to grow rapidly. This recommendation is not confined to fruit trees, but is also applicable to forest trees and shrubs. Indeed as regards these, even when the ground presents some expensive obstacles to cultivation, the more rapid growth often pays for the outlay. At no great distance from here is a Chestnut coppice, one portion of which was planted on the ground unprepared in any way, whilst for the other the ground was trenched, and a considerable quantity of stones removed. It was exceedingly stony, with very little surface soil, and that composed of two-thirds stones embedded in a hard impenetrable soil resembling an old road more than anything else, and even when in cultivation it had anything but an inviting appearance; nevertheless, on such a soil many kinds of trees thrive well, and quickset hedges particularly so, but all are the better of the ground having received a good grubbing-up. I am not certain whether trees receive so much benefit from ground of this description being afterwards laid down in grass as in some other cases; at all events it is not so often done, for the reason that grass is by no means a productive crop on such soils. The above, however, is an exceptional case; let us now endeavour to find a reason for the advantages which middle-aged fruit trees unquestionably derive from being left to themselves in a great measure, especially at the root.

Trees, like men, have their period of youth, maturity, and old age, and when due encouragement has been given in the first period of life, the succeeding stages derive the benefit. Now, in a fruit tree destined to attain great dimensions, the earlier period of its existence is devoted to growth rather than to its producing fruit, and if let alone or judiciously managed its period of bearing comes on by degrees, and in

just proportion its growth is less rapid. Though its growth and bearing vary according to the seasons and other circumstances, its maturity approaches sooner or later, and the aim of the cultivator is to retain it in a healthy state as long as possible; nevertheless, there is a time beyond which his utmost skill is insufficient to do this; probably some natural cause, as an adverse season or other misfortune, may bring on the tendency to decay, and though the tree may have all the attention and assistance that can be given, it must in time succumb. I need hardly mention, that most trees become more prolific in blossom as they become older and decay sets in; but the lack of vigour in most of those blossoms is such that a great proportion of them fall off abortive. This, however, is a well-known state of things, but whether the decay of a tree is hastened by that cause, or retarded by cultivation, is a matter now left for our consideration, and from what observations I have been able to make, I should be inclined to say that the spade is an enemy to old trees, and, coupled with that, I am strongly disposed to add, that the knife is so also. Of course, I am speaking of old full-grown standard trees past their best, for, like ourselves, old trees are unable to bear violent changes when they no longer possess the vigour requisite to enable them to recover from any injury we may have done them. I certainly have never seen a fruit tree in a cultivated orchard so old as those in some that have been long laid down in grass, neither do our walls present us with such old specimens.

In classing both the knife and spade as enemies to great age, I expect many will except the latter, and, perhaps, adduce some good reason for doing so, but let us take an ordinary but somewhat severe example and mark the result. Take two aged Apple trees that are still in fair bearing condition, and supposing both to be alike in health, &c., let one of them be headed down to a dozen or twenty branches, and grafted in the usual way. The scions we shall suppose to take pretty well (as they generally do if well managed), and a good growth ensues, which is followed by a certain amount of cutting and pruning in the succeeding winter to give the proper shape. This is repeated for two or three seasons, when, probably, it is discovered some spring that a large limb involving quite one-third of the tree has died, and, probably, next year the remainder follows. The other tree on the contrary never having been mutilated in any way will remain in much the same condition as before, a little older-looking, certainly, but still likely to live for many years. This picture is by no means overstrained, it being, in fact, of so frequent occurrence that the heading down of old trees is very little practised now, and many whose experience is worthy of much attention, have expressed their disapprobation of meddling with old trees in any other way than by entirely removing them, affirming that extreme measures only tend to hasten their dissolution. I could point out many examples where old trees that had become crowded with mossy-covered branches, did not seem to produce any more or any better fruit by having their branches thinned, and cut into better form. Nature seemed to rebel against the proceeding, and refused to make amends in any way for the injury done. That there are exceptions to this I admit, but as the present article was intended to relate more particularly to the roots and their action in solid or disturbed ground, the subject of pruning may be left until another opportunity.—J. ROBSON.

#### CROSS-BREEDING STRAWBERRIES.

As a hybridiser of flowers and fruits I cannot let pass in silence the article inserted in your Journal at page 362, written by M. de Jonghe, of Brussels, in which he says all Strawberry flowers are fertilised before the blooms expand. If so, why have many thousands of forced plants gone blind this year? and, in fact, why do thousands go blind every year?

If M. de Jonghe could get a good Strawberry that would set its flowers as he says, he would make a large sum of money by it. The fact is nothing is so easy to fertilise as Strawberry blooms, but, to make sure of them, the plants should be forced a little in order to flower before the very hot weather commences. In dull weather I have found in Strawberry flowers it would be sometimes three days after

they expanded before the pollen made its appearance: consequently, as I have proved, nothing is more simple to effect than their fertilisation.—JOHN STANDISH, *Royal Nursery, Ascot.*

#### ROYAL HORTICULTURAL SOCIETY'S ORCHID SHOW.

This was held on Saturday last, the 13th, and though none of the great exhibitors of this beautiful order of plants put in an appearance, there was a tolerably good bank chiefly contributed by Messrs. Maule & Son, of Bristol, and Messrs. Lee, who also sent an extensive collection of stove and greenhouse plants.

In Class 1, *Aërides*, *Vanda*, and *Saccolabium*, Messrs. Maule were the only exhibitors, and had a first prize for the beautiful white and pink *Aërides crispum*; a fine example of the Foxbrush, with a spike nearly 2 feet in length, Veitch's *Vanda suavis*, and a good variety of *Saccolabium guttatum*, with eight spikes, grown, as well as several others of Messrs. Maule's specimens, in pottery-ware imitations of stumps of trees, varying from 16 inches to 3½ feet in height, having snags here and there with holes in them, and the interior stuffed with pieces of cork.

In Classes 2, 3, 5, and 8, for *Cattleyas*, *Lælias*, *Oncidiums*, *Miltonias*, *Odontoglossums*, *Anætochils*, and miscellaneous nine, there was no competition.

Class 4 was for three *Cypripediums*, and here Messrs. Maule took the first prize with pans of *C. barbatum purpuratum*, and *multiflorum*, each upwards of 2 feet across, and containing about forty flowers. The plants, it may be remarked, were divided and planted out at equal distances apart, and each bore a flower. The third species was *C. calycinum*, with small greenish yellow flowers, having short tail-like appendages, after the manner of *caudatum*. The second prize was awarded to Mr. Cullen, gardener to W. Wentworth Buller, Esq., *Strete Raleigh*, Devon, for *C. multiflorum*, a large-flowered variety of *C. barbatum*, and the curious South American *C. caudatum*, with two remarkably fine, highly coloured flowers with each of the tails 20 inches in length.

Class 6, was for Nurserymen's miscellaneous collections of twelve, in which Messrs. Maule were first with a fine pan, 28 or 30 inches across, containing divided plants of *Cypripedium barbatum nigrum*, bearing some forty-five blooms, *Vandas*, *Foxbrush Aërides*, *Saccolabiums retusum* and *ampullaceum*, *Dendrobium nobile*, and a good example of *D. Devonianum*, of which the cream, orange, and purple flowers render it so splendid an object for exhibition; *Aërides crispum* and the useful and the free-flowering *Oncidium divaricatum*, completed the number of this collection. Messrs. Lee came second with a small plant of *Cypripedium hirsutissimum*, a good specimen of *Dendrobium nobile*, *D. Dayanum*, and *D. Wallichianum*, *Oncidium altissimum*, *Phalænopsis grandiflora* and *amabilis*, each with three spikes of bloom, *Cypripedium barbatum* and its variety *nigrum*, *C. Hookeriæ*, with the flowers very bright in colour, and *Cattleyas* in good bloom. Mr. Parker, Tooting, was third with a collection containing several good *Vandas*, and varieties of *Cattleya*, *Lycaste Harrisoniæ*, a very good plant with fifteen flowers, *Trichopilia coccinea*, *Phalænopsis grandiflora*, and a variety of this called *aurea*, in which the yellow eye was larger and of a more golden colour than the plant usually presents.

A miscellaneous collection of six from Mr. Robson, gardener to G. Cooper, Esq., had a first-prize. It contained the pretty *Cattleya amethystina*, the beautiful and free-flowering *Lycaste Skinneri*, one of the best of winter-flowering Orchids, *Oncidium sphacelatum*, with two good spikes and a small one, *Phalænopsis grandiflora*, *Vanda tricolor superba*, and *Cattleya Mossiæ*. Another collection also came from the same exhibitor; and one of three from Messrs. Maule, for which a first prize was awarded, it being the only exhibition in the class for that number.

In single specimens by far the finest was a magnificent plant of *Vanda suavis* (Veitch's variety), from Mr. Hill, gardener to R. Hanbury, Esq., *The Poles*, Ware, standing at least 4 feet high, and bearing twelve fine spikes of its gorgeous cream-white and crimson blooms. It received a first prize, also Mr. Wilson Saunders' prize for the finest

single specimen. A second prize was awarded to Mr. Sherratt, gardener to J. Bateman, Esq., Biddulph Grange, for the Bornean *Cœlogyne pandurata*, bearing three fine spikes of its large flowers, green, conspicuously marked with black in the lip, and which differ so much in colour from those of the other species of this showy genus. A similar award was made to Mr. Smith, gardener to S. Norris, Esq., Altrincham, for a fine spike of *Renanthera coccinea*, a plant which of late years has but very rarely found a place on the exhibition tables. In this case the panicles were more compact, and the flowers of a brighter colour, than usually seen. The new *Phalaenopsis Luddemanniana* was shown by several exhibitors, but in greatest perfection by Mr. Charles, gardener to R. Barnett, Esq., Blackheath Park, his plant having two spikes, bearing in all seven of its beautiful amethyst-coloured flowers, conspicuously barred with brown. For this a first prize was awarded; and second prizes went to Messrs. Low, who introduced it into this country, and to Mr. Robson, gardener to G. Cooper, Esq., for smaller plants of the same *Phalaenopsis*. Other Orchids consisted of a fine specimen of *Trichopilia crispa*, shown by Mr. Pilcher, gardener to S. Rucker, Esq.; some good *Cattleyas* from Mr. Wilson, Dulwich; and *Cypripedium Hookerianum* from the Society's Garden, from which came also a new *Physurus* with beautiful olive green leaves and white markings, *Anthurium cordifolium*, Ferns, *Lycopods*, &c.

Although the special object of the Show was Orchids, there were, nevertheless, many excellent specimens of stove and greenhouse plants furnished by Messrs. Lee, which contributed much to the interest of the exhibition. Among them were large plants of *Rhopala magnifica*, *corcovadense*, and *De Jonghi*, the metallic green *Alcascia Lowii*, *Cyathea Smithii*, relieved by flowering plants, such as *Azaleas*, *Heaths*, *Pimeleas*, *Chorozemas*, *Boronia tetrandra*, the orange-scarlet-flowered *Leschenaultia intermedia*, *Adenandra fragrans*, &c. For these Messrs. Lee had an extra prize; and a like award was made to Mr. W. Paul for his collection of Beaton's *Geraniums*, which have been favourably noticed on more than one occasion in these pages. From Mr. Bull, too, came an interesting collection of novelties, conspicuous among which were the beautiful *Bertolonia margaritacea*, *Asplenium myriophyllum*, with finely-divided and very elegant fronds; *Sauraja sarapigiensis*, with ample foliage, having red midribs and veins, and his curious *Hose-in-hose Mimulus*. A variegated *Sedum* or *Sempervivum*; *Podocarpus macrophyllum*, with some of its shoots entirely white, others simply variegated; *Dracæna stricta*, *Anthurium cordifolium*, a noble specimen of *Cibotium princeps*, *Zonate Geraniums*, and various other plants were also shown by Mr. Bull.

Mr. Gardiner, gardener to E. P. Shirley, Esq., Stratford-on-Avon, exhibited, in addition, dishes of *Reinette du Canada* and *Hanwell Souring Apples*, of good size, and in excellent condition.

#### PROPAGATING AND AFTER-MANAGEMENT OF BEDDING AND OTHER PLANTS.

THIS is a subject possessing a large amount of interest to those who are fond of plants, and of great commercial importance to those who gain their living by their cultivation and sale. What an amount of pleasure does the amateur experience in watching the little cuttings day after day, until he sees by their inclination to grow, that they have formed roots, and are to a certain extent independent of his care and watchfulness. By the gardener who requires a large stock of bedding-out plants, whose space is limited, and who has not the convenience of a propagating-house, the following simple plan of making a propagating-bed will be found useful. In the first place procure four stout oak posts, these are to be let into the ground one in each corner, at distances varying according to the size of the frame and bed for propagating. The two back posts should be left about 2 feet 6 inches out of the ground, and the two front posts about 18 inches above it. When the four posts are firmly fixed in the ground nail on the top of them four good pieces of wood, about 4 inches by 4 inches, to form the sides or bed on which the frame is to rest. Care should be taken to measure the bottom of the frame before the

cross-pieces are nailed to the posts, so as to have them of the exact size of the frame. Cross-pieces should then be put on to form the bottom of the bed, space being left between the cross-bars so that the heat may come through the bottom. After the pieces have all been put in the proper place, and the whole nailed together securely, the frame should be placed on the top. About 2 inches of broken bricks is then put in the bottom, and above this another layer of finer broken bricks or charcoal; but there must be no dust or dirt amongst it, the object being to keep the bottom as porous as possible, so that the heat may pass freely through, and be regularly distributed over the bottom of the bed. Next place 4 or 5 inches of some light, porous material in the frame for plunging the pots in; this completes the internal arrangement of the bed. A lining should then be built about 3 feet wide on all sides of the frame, leaving the space under the frame open—*i.e.*, there must be no manure or leaves pushed under the bed. The lining should be built up square with the four posts on which the frame rests. The materials best suited for this purpose are two parts leaves, and one part good stable manure. The lining should be built up to within 6 inches of the top of the frame, plenty of water being used as the work proceeds, and well trodden to consolidate it as much as possible. As the lining sinks, which it will do in a day or two after it has been made, more leaves, &c., should be placed on the top, and this should be continued till it has become firmly set. In about five days from the time the linings are finished the bed will be ready for receiving the cuttings.

The object in leaving the open space below the bed, is—First, to cause the heat to be regularly distributed all over the bottom of the bed. Secondly, by these means the whole of the plunging material becomes warmed alike, or nearly so, and the centre of the bed is nearly as warm as the outsides. Thirdly, there is no fear of burning, nor of any rank steam getting into the bed. The hot steam is confined in the chamber below the bed, and comes regularly through all over the bottom. Another great advantage is gained by a propagating-bed in this way—namely, no worms, nor any other insects can get in. I find the best material for plunging in is the cocoa-nut refuse sifted through a fine sieve. It is very free from smell, is very light, and keeps the pots nice and moist, and never becomes soddened. To keep them sweet and clean the lights and the woodwork of the frame inside should be washed about once a fortnight. Much depends on this. Before this washing is commenced the cutting-pans should all be taken out and put into another frame, to prevent injury, and after the frame is cleared of all the pots and pans, the fine plunging material should be scraped back from the sides of the frame all round to let the water pass freely through the bottom without wetting the cocoa-nut refuse. After the sides have been washed this may be put in its place again, and the cuttings brought back. Once a-week the linings, will want stirring up, and fresh water, manure, leaves, &c. should be added, but care must be taken in doing this not to let the cold air into the chamber. If this is done much heat is lost, and the cuttings that are in the frame at the time receive a check which will cause many of them to damp off. Cuttings of *Verbenas* will readily strike in a frame of this sort in four or five days. Cuttings of these are put in, struck, and boxed off, and make good plants in less than a fortnight. In a two-light frame, 8 feet by 5 feet, mounted on four posts, and managed as above described, since the second week in March I have struck about 15,000 plants of *Verbenas*, *Lobelias*, &c.—J. WILLS.

(To be continued.)

#### EFFECTIVE COMBINATION OF COLOURS.

I HAVE now a combination of colours coming out at the same time, and that a time when the newness and freshness of colour is cordially appreciated, which may be worth recording. Two large plants of *Berberis Darwinii*, one mass of golden flower, crown the summit of a small piece of rock-work; between them the perennial white *Candytuft* forms a mass of pure white, and below is a sheet of the *Aubrietia grandiflora*. The tender green of *Griselinia littoralis* flanks one of the *Berberis*, and in the full sun the effect is very

striking. We often lose by not placing near each other the plants which not only harmonise in colour, but come into flower at the same time, so that perhaps this hint as to the effect of one accidental combination may be of use.—C.

### DOUBLE AND TREBLE CROPPING.

I THINK it would not be amiss if some of our practical men were to give us a few articles on kitchen-gardening, and we were to compare notes. If each gave his own experience it would be very beneficial to young gardeners, particularly in these go-a-head days, and I have no doubt but that you will give us your assistance.

In the first place I am not writing to or for our more fortunate brethren who have their two or three acres of kitchen garden, and a good staff of men to work it, but to those who are situated like myself, with about half an acre of ground on which to grow fruit, vegetables, and salads for a large establishment, and living within an easy distance of Covent Garden market, which I consider makes a great difference in the wants of the kitchen department.

Now, suppose we take a piece of ground intended for early Peas. After having it dug deeply and well manured the Peas are sown on the 1st of January, and are cleared off by the middle of July; the ground is then dug again and planted with Coleworts, not forgetting to put plenty of manure in with them. The Coleworts come in nicely for early autumn use, after which the ground is ridged, and Endive planted in the furrows, making three crops in one year, and leaving the ground in good order for the next.

Again, by sowing the Scarlet Runners and tall-growing Peas 5 or 6 feet apart, I can plant two rows of winter stuff between the rows, so that when the Peas, &c., are done with, and the sticks and haulm cleared off, I have a good coat of manure forked in, and the earth worked towards the stems of the plants, leaving all neat and clean for the winter; or, if appearances are not an object, the pea rods being left form a capital protection for the more tender kinds of winter crops, as Broccoli, Savoys, &c.

Then, again, as regards the ground upon which the spring Cabbages are growing. Between the rows of Cabbage I plant Potatoes, so that when the Cabbages are cut the Potatoes are ready for earthing up. After the Potatoes are taken up, and the ground well manured, I generally sow my winter Spinach on that piece. For early Potatoes I select a piece of ground lying under the south aspect wall. When the Potatoes are planted I sow Radishes and Lettuces on the top, so that when the Radishes are all pulled, and the Lettuces pricked out elsewhere, the Potatoes are ready to flat-hoe. When the Potatoes are dug the ground is planted with the first batch of Savoys, which are generally off in time to allow of the ground being trenched ready for the next season's work. Between the rows of second early Peas I generally throw out my Celery trenches, and before the Celery is ready to plant I work my Cauliflowers off in the same trenches, and by the time the Cauliflowers are cut, and the Celery just established, the Peas are ready to come off, leaving plenty of room for the Celery, earthing-up, &c. Thus by deep digging, frequent flat-hoeing, changing the crops, and last, though not least, an unlimited supply of manure, I generally manage to have two or three crops a-year off the same ground, and seldom or never fail to have a good supply of vegetables and salads—in fact the past summer and winter would soon convince one whether his system were right or not in that respect, and though I must confess it is hard work for the land, yet in my opinion the land is better every year.

I do not know that there is anything new in my system, but the desire to impart information as far as the preceding random hints will do so, has induced me to pen the above with the hope that some one more capable than myself will take the matter up, and give us a few good articles on kitchen-gardening in general, and one of the first to profit by them will be—BURNWOOD, P. D.

LIVERPOOL FLORAL AND HORTICULTURAL EXHIBITION SOCIETY.—The meetings of this Society will be held in the Botanic Garden on the 25th of May, the 29th of June, and

31st of August. Liberal prizes are offered for Azaleas, Pelargoniums, and other flowering plants, also for fruit and vegetables.

### THE POLES NEAR WARE.

ABOUT a mile and a half from the Ware Station of the Great Eastern Railway, is The Poles, the seat of R. Hanbury, Esq., one of those gentlemen, who, possessed of an ample fortune, delight in gardening and rural pursuits. Entering from the road leading to Wade's Mill by a modest lodge, the visitor passes along a winding drive through a pleasantly undulating park of about a hundred acres, dotted with Oaks and Elms, and old Thorns, and through a belt of newly-planted Rhododendrons, which when they shall have attained a larger size, will, doubtless, in their flowering season have a very ornamental effect. In front of the mansion is a well-kept lawn, with here and there Wellingtonias, Abies Douglasii, and Cedars of Lebanon, and further off the pinetum. Turning, however, to the right we come to the conservatory on the south side of the house. It opens into the drawing-room and library, and at the time of our visit was filled with Camellias, and various other flowering plants, together with a noble specimen of *Cyathea medullaris*.

In front of the conservatory and this side of the mansion runs a terrace, overlooking a roseroy, which is planted with a good collection, consisting of Hybrid Perpetuals, whilst Tea Roses are trained against the six-feet-high terrace wall. The centre of the roseroy is formed by a pedestal and vase encircled by four quadrant beds, then a circular walk, and exterior to this twelve other beds converging towards the centre, the whole being surrounded by four borders separated from each other by the four principal walks, which meet at right angles at the vase in the centre. Above, on the terrace, there are twelve beds on each side of the walk, six oblongs with the corners swept out alternating with the same number of circles, and the whole planted with standard Roses. Continuing onwards we come to a ribbon border planted with—first row, next the edge, Hyacinth Maid of Perth, blush; second, Rex Rubrorum Tulips; third, Dr. Lindley Hyacinth, purple; fourth, Rex Rubrorum Tulips; fifth, double Roman Narcissus. This border had still a cheerful effect, although the bright sun had somewhat told on the flowers. To reach this ribbon border, however, we have passed on our left the greenhouse, fernery, and Orchid-houses, forming three sides of a square in which was a small garden devoted to sweet-scented plants. In the stove were three fine plants of *Musa Cavendishii*, which is here fruited every year; and Mr. Hill, the persevering and very intelligent gardener, cut forty fruit at Christmas off one plant. A *Bougainvillea* trained on the roof contributed by its rosy bracts, along with Begonias, Francisceas, and other flowering plants, to give this house a gay appearance. The fernery contained a well-selected and healthy collection of Adiantums, Aspleniums, Davallias, Lastræas, &c., and remarkably fine plants of *Cibotium princeps* and *Schiedei*, *Lonchitis pubescens*, *Gleichenias*, and *Marattias*. A plant of *Thunbergia Harrisii* extends for 15 feet along the roof, and in the course of the season produces thousands of its beautiful blue and yellow flowers. In the Orchid-houses, three in number, Veitch's variety of *Vanda suavis* had three splendid spikes of bloom, and several more were coming; the lovely *Cattleya Skinneri* was also in fine bloom, besides which there were fine examples of *Aërides*, *Ansellia africana*, *Vanda teres* and tricolor, and numerous plants of *Phalænopsis grandiflora*, which is much in demand for cutting; the new and beautiful *P. Schilleriana*, which had been in bloom for the last three months; *Brassavola Digbyana*, *Chysis Limminghi*, *Dendrobiums*, *Cattleyas*, *Lycastes*, *Cypripediums*, &c.

In these houses *Alocasia metallica*, pot plants of *Bougainvillea glabra*, Ferns, and *Amaryllids*, also found a place, whilst on the roofs were trained *Lapagerias*, *Mandevilla suaveolens*, and *Hoya imperialis*, which had been in bloom all the winter, and was so still. In the greenhouse, too, a good show of flower was kept up with *Calceolarias*, that valuable winter and spring flowering plant, *Imantophyllum miniatum*, *Eriostemons*, *Chorozemas*, *Heaths*, &c.

Quitting the houses, on passing the west side of the fernery we observed two small beds filled with Tea Roses,

pegged down, and which when in bloom, besides scenting the air with their delightful fragrance, are stated to be very effective. In very severe weather these are protected with mats. Adjoining these beds is a bank of rockwork planted with Alpines to the number of 400 or 500. A winding walk leads to the north front of the mansion, and on the opposite side of the walk beyond a belt of the different kinds of Hollies, and surrounded on the other sides by Berberies, lies the pinetum, about an acre in extent. This was planted only ten years ago, but already some of the specimens have attained a considerable size. A *Picea Nordmanniana*, certainly one of the finest in the country, perfectly erect, and well furnished throughout, was from 24 to 25 feet high, and *Picea pinsapo*, 15 feet high, and 10 feet through. The largest *Wellingtonia* was 13½ feet high; one only 6 feet high had three cones on it, but as stated at p. 359, this tree produces cones at a very early age. Cedars of Lebanon had also attained a good size, one was estimated to be nearly 40 feet high, and there were several from 25 to 30 feet. Of other species there were good thriving specimens of *Thujaopsis borealis*, *Cryptomeria japonica*, *Picea nobilis*, *Abies Douglasii*, *A. orientalis*, *Juniperus chinensis*, *thurifera*, *Taxodium sinense* or *Glyptostrobus pendulus*, a very elegant tree 6 feet high; the *Dovaston Yew*, deserving more general cultivation, on account of its prostrate habit; and several pretty pygmies, such as *A. excelsa Clanbrasiliana*, and *excelsa elegans*, ranging from a foot to 1½ foot high. One great feature of this pinetum, and indeed of the garden generally, is that every tree is legibly named, adding much to the pleasure and instruction which such a garden is capable of affording. We mention this more particularly because in some public gardens plants are not unfrequently unnamed, and consequently lose much of their interest to the many.

The kitchen and fruit garden covers a space of five acres, of which two acres are enclosed by walls 15 feet high, built hollow on the same plan as those at Chiswick, which, unlike other forms of hollow walls, have exactly the same appearance as a solid one. The wall on the south side is 300 feet long, giving of course 300 feet of south aspect and a corresponding extent of north aspect, and at right angles to this wall run two others, and one dividing the enclosed space up the centre. Each of these is 240 feet in length, and the whole, consequently, give 720 feet of west aspect and a like extent of east aspect. The borders are 15 feet wide, and variously cropped to within 4 feet of the wall. The south aspect is covered with Peaches and Nectarines now rapidly covering the wall, and when this is effected all riders will be removed. The trees were chiefly *Grosse Mignonne* and *Barrington Peaches*, and *Violette Hâtive Nectarines*, and were all in excellent bearing condition. But it was on entering the walled-in garden that we were more especially struck with the appearance of the trees. The walls were literally covered with blossom, and the trees in a healthy bearing state from top to bottom. The north aspect is chiefly occupied with fan-trained Plums and Cherries, the former consisting of *Coe's Golden Drop*, *Magnum Bonums*, *Angelina Burdett*, *Kirke's Orleans*, and *Victoria*; the latter of *Elton*, *Black Tartarian*, and *Morello*, one tree of which alone extends over a width of 25 feet. The east and west aspect walls are covered with excellent horizontal-trained Pear trees of the best varieties, as *Duchesse d'Angoulême*, *Louise Bonne* of *Jersey*, *Glou Morceau*, *Thompson's*, *Althorp Crasanne*, *Josephine de Malines*, *Easter Beurré*, &c., *Plums*, and *Cherries*. Along that side of the walks farthest from the wall, at 6 feet from the edge, are planted about 200 pyramid Pears, from 12 to 18 feet apart. These were all root-pruned two years ago, and were, like those on the walls, white with blossom. The interior was variously cropped with Peas, Carrots, Cauliflowers, Asparagus, and other vegetables, and the supply is supplemented by the produce of the outside slips, in which there are standard Apples, Plums, and other fruit trees.

We now come to the south-aspect wall on the north side of this garden. Here there are four vineries each 30 feet by 15 feet, and a Peach-house 40 feet long by the same width. In the first house heated by five rows of four-inch pipe were fine crops of *Black Hamburg*, *Trentham Black*, *Muscat Hamburg*, and *Frontignans*, and in a succession-house *Black Hamburgs*, *Lady Downe's*, and *Muscats* in

pots, the two former having set a good crop, and the last being just started. We also noticed good crops of *Strawberries* on the shelves of these houses. The fourth vinery was a *Muscat-house*, in which fresh Vines had been planted to replace the old. The most pleasing sight, however, was the *Peach-house*, the roof being covered with two fine trees bearing a profusion of fruit which had stoned, the foliage very healthy and free from all appearance of insects, and not a fallen fruit to be seen.

A span-roofed *Peach-house* formerly an orchard-house, but now heated, 36 feet long, 18 feet wide, and 10 feet high to the ridge, was also planted with *Black Hamburgs* and *Buckland Sweetwater Vines*, trained along the ridge, whilst on shelves were numerous pots of *Sir C. Napier* and *President Strawberries*, bearing very freely. A second span-roof was devoted to *Figs* well set with fruit, the kinds being chiefly *Brown Turkey*, *White Ischia*, and *Early Violet*, which produces a small sweet fruit, is a very free bearer, and excellent for forcing. Other houses contained pot Vines started to come in at Christmas, *Bowwood Muscats* just colouring, *Oranges* in pots grown chiefly for their flowers, good crops of *Strawberries*, *Kidney Beans*, and *Cucumbers*. Of the last Mr. Hill has a very prolific variety of his own, raised by him several years ago between the *Manchester Prize Cucumber* and *Black Spine*. The fruit averages 18 inches long, and is produced in twos, and sometimes three or four at a joint.

There still remain two span-roofed plant-houses to notice: the one, an *Azalea-house*, contained very good specimen plants, such as are to be seen at the London shows, new *Aucubas* and other *Japanese plants*, *Calceolarias*, and miscellaneous flowering plants; the other, a *rosery*, contained *Tea Roses*, both in pots and planted out, and trained up the pillars. Here *Gloire de Dijon*, *Madame de St. Joseph*, and several others were in fine bloom.

Various pits contained a good stock of bedding plants, herbaceous *Calceolarias*, *Cinerarias*, *Mignonette*, *Japan Lilies*, including *Lilium auratum*, and other plants for indoor decoration; and there was besides about 60 yards run of frames for forcing vegetables in winter and *Melons*, &c., in summer. At the back of the north wall of the kitchen garden were the men's rooms, not the small, low, dark, and badly-ventilated rooms too commonly met with, but 14 feet square, and 9 feet high, heated by hot water, and with ample provision for air and light. The number of hands employed is twenty-one, but only six are lodged in the grounds. In the same range is the stable, *Mushroom-house*, in good bearing, *fruit-room*, *tool shed*, and *Mr. Hill's office*. Where there is such a liberal employer as *Mr. Hanbury*, and such a zealous and well-skilled servant as *Mr. Hill*, great things may be expected, still we were not prepared to meet with such high-keeping and thorough efficiency in every department, everything that was done was well done, and it is no exaggeration to state that there was not a weed to be seen.

## LACHENALIA, OR CAPE COWSLIP:

ITS CULTURE, AND A SELECTION OF THE FINER SPECIES.

We cannot but regret that those singularly beautiful and interesting spring-flowering bulbs the *Lachenalias*, such great favourites with our forefathers, are now so much neglected, and that they have been driven out of cultivation by many of the less-deserving novelties of the present day.

The *Lachenalias* are all spring-flowering bulbs, natives of the Cape of Good Hope and adjoining parts of South Africa; they belong to the same natural order (*Asphodeleæ*) as the *Hyacinth*, *Star of Bethlehem*, *Garlic*, and the *Musk* or *Grape Hyacinth*, and to the latter they are closely allied. This curious and interesting genus contains numerous handsome species and varieties, a great many of which have now disappeared from our collections, chiefly, no doubt, from the plants having been neglected after blooming, or placed out of doors and exposed to the heavy rains, where, owing to their being grown in pots, they frequently become sodden—a circumstance which is sure to cause the bulbs to rot, these being very succulent, scaly, and covered with a dry scaly bark very different from that of most other bulbs.

The different species of *Lachenalia* or *Cape Cowslip* are

not only valuable for the duration of their flowers, but for the varying bright tints which they assume whilst they are in bloom, for the flowers of many of them are constantly on the change, from rosy infancy to yellow maturity; the flowers also assume an elegant pendent position on the stem, expand but little at the mouth of the tube, and have the appearance of one flower partly within another—an appearance which arises from the outer or shorter parts being the sepals, and the inner or longer ones the petals. *Lachenalias* may be had in flower from January to June, if a portion of the bulbs be introduced into the forcing-pit at different times along with other early spring-flowering bulbs; for the *Lachenalias* require no more care than a *Hyacinth*, and last quite as long, if not longer, in bloom.

Most of the species have various-coloured flowers, spotted leaves, and beautifully-mottled flower-stems, which rise from 6 to 12 inches in height, and are mostly furnished with from twelve to eighteen loosely-placed, drooping, tubular-shaped flowers, which in most cases as the blossoms advance change colour from bright red and deep yellow to a pale red or yellowish-green. A few of them, however, have self-coloured flowers, which are either orange, yellow, red, pale blue, or white, changing with age to a pale blush. The leaves are mostly lance-shaped, glossy green, recurved, and beautifully spotted on the upper surface; the flower-stems are also prettily marbled, and, together with the spotted leaves, contrast well with the graceful spikes of pendent or semi-pendent flowers, the exquisite combination of whose changing hues defies every attempt of the pencil, and description or portraiture fails to do them justice.

*Lachenalias* will succeed in a warm south border, if well protected in winter by a hand-glass, and other dry covering in severe frost. What, however, is much better, and frequently more convenient, is to place half a dozen bulbs in a pot of light soil, in October, using equal parts of fresh loam, rotten leaves, and fine sand, and affording them the protection of a cold pit until the spring, when they can be planted out in the open border, and sheltered for a time with a hand-glass.

If the bulbs are intended for in-door decoration, they should be placed on the top shelf in the greenhouse near the light, and but sparingly watered during the winter; but freely so when the plants are in a growing or flowering state. When the plants have done flowering, the pots should be placed in a cold frame or pit, and the plants encouraged to complete their growth, and perfect their bulbs, for upon that all future success depends. When the bulbs have lost their foliage, they should be taken out of the soil and kept dry in as cool a place as possible, that they may not begin to grow too soon. By this mode of treatment the bulbs may be either at once planted out in the warm border in spring, and protected by a hand-glass, or be potted in the autumn (in the end of September or beginning of October) and placed in a cold pit, secure from frost, where they must be kept tolerably dry until wanted for forcing, placing in the greenhouse, or planting out in the spring. The different kinds of *Lachenalia* increase freely by offsets from the old bulbs. Even the leaves under certain circumstances produce bulbs, and beautifully illustrate the analogy between bulbs and buds, the affinity of which is more perfect than many persons probably imagine. Of this the *Lachenalias* present a pretty example, bulbs being produced from the leaf and flower-stem. Of this curious phenomenon Sir James Edward Smith relates that he had scaly bulbs from flower-stalks of the *Lachenalia tricolor*, whilst laid for many weeks between paper to dry, and which on being put into the ground became perfect plants. Mr. John Rogers also relates another instance which occurred in his garden near Sevenoaks, in Kent. The leaf of a species of *Lachenalia* having been broken off before the sap had descended to the bulb, on the broken edges and lower part of the leaf there were produced upwards of forty small bulbs, varying in size from that of a pea to a small pin's head.

Many of the names given to *Lachenalias* in catalogues are, no doubt, synonymous, or applied to trivial varieties. The following selection, however, contains the finer and more distinct kinds now to be found in cultivation.

**LACHENALIA TRICOLOR** (The Three-coloured Cape Cowslip).—This is one of the oldest and handsomest kinds we have. The flower-stems rise to a height of 8 or 9 inches,

and generally produce from twelve to eighteen flowers, which are loosely placed, drooping, tubular-shaped, and composed of three colours—namely, bright red, yellow, and green. The colours of the flowers, however, have but little permanence, for they change considerably as the flowers advance to maturity; being when young of a bright red and greenish yellow, while when fully matured they are of a light yellow, stained near the ends of the petals with pale green. The leaves and flower-stems of this species are beautifully spotted and marbled with reddish brown. There are two distinct forms of this plant, one with broad leaves, and another with narrow ones, which latter is frequently named *quadricolor* in gardens.

**LACHENALIA FLAVA OR AUREA** (The Golden Yellow Cape Cowslip).—This is a beautiful kind with large, tubular-shaped, golden yellow flowers and spotted leaves. The flowers are more or less drooping, and produced on stems from 6 to 9 inches long.

**LACHENALIA LUTEOLA** (The Pale Yellow Cape Cowslip).—This is a strong-growing kind with flower-spikes from 8 to 9 inches high, furnished with numerous partially drooping, tubular-shaped, light yellow flowers, stained with pale blush when young. There are two varieties, one with spotted, and the other with unspotted leaves and flower-stems.

**LACHENALIA PALLIDA** (The Pale Blue-flowered Cape Cowslip).—This kind has flower-stems from 9 to 12 inches long, furnished with large tubular-shaped flowers of a pale blush colour when young. There are two varieties of this kind, one the minor with very pale blue flowers, which change to blush when fully blown; while the other has bluish-coloured flowers, and a more robust habit of growth.

**LACHENALIA ANGUINEA** (The Snake-stemmed Cape Cowslip).—This has spotted leaves, and beautifully marbled flower-stems, from 9 to 12 inches high, sparingly furnished with tubular, bell-shaped, drooping, white and green flowers, which fade away to pale blush with age.

**LACHENALIA PENDULA** (The Pendulous Cape Cowslip).—This is a fine robust-growing kind with large, bright, parti-coloured drooping flowers, deep red, bright yellow, and pale green when young, but these colours become much lighter or more pallid as the flowers advance to maturity. The flower-stems grow from 9 to 12 inches high. There are two very distinct varieties, one with spotted leaves and flower-stems, and another with unspotted ones.—GEORGE GORDON, A.L.S.

#### CUTTING DOWN YEW HEDGES.

If the Yew trees are planted thick enough, it is not absolutely necessary to cut them down, as directed in answer to "R. R.," page 366. They may be deprived of their branches from the base to the top, and they will break thickly all over; or the branches on one side may be lopped off, and the others left on for awhile, to be served in due time in the same way. Be careful where you put the loppings. Yew loppings killed two beautiful Guernsey cows that I gave to Lord and Lady Curzon on their marriage.—W. F. RADCLIFFE, *Tarrant Rushton*.

#### THE MODERN PEACH-PRUNER.

No. 9.

WE now come to the consideration of the shorter shoots of the Peach. These valuable classes have hardly met with the notice they deserve at the hands of long-pruners. Indeed, in some works it is recommended to suppress them as much as possible. This is a great error; for other writers, such as Knight and Dubreuil, recommend their careful preservation, wherever found at all possible; and in the works of such masters of close pruning as Professor Gressent, of Orleans, and M. Grin, of Chartres, the main dependence for fruit is placed on Class 5, which is well known, moreover, to produce the finest specimens. Very close pruning, such as is well suited to orchard-house trees, rarely fails to develop Classes 5 and 7 in great abundance, especially in the case of established trees. Though all the classes of this division occur under every form of training, they are peculiarly the result of that sudden concentration of the

sap, during the period of its greatest ascent, at the base of the shoot, which is produced by judicious summer stopping. In some mysterious way an obstacle is created, which appears to concentrate the cambium in the cellular tissue near the base of the nascent bud, and by this retarded circulation to produce eventually a cluster of blossom-buds, which are eminently fruitful. It is not, however, pretended that late summer stopping would be so successful.

#### 2<sup>ND</sup> DIVISION OF PEACH SHOOTS.

5. THE CLUSTER SHOOT or SPUR (fig. 5).—The word cluster, which so appropriately represents the appearance of the blossom-buds *B*, round the terminal leaf-bud *C*, is synonymous with the French term "bonquet." By this last name this particular spur is known all over France. Dubreuil calls it *rameau à fruit bouquet*; and Gressent and Lepère call it *bouquet de mai*. Knight appears to designate it as a "spur," and the word "cluster" may be considered an appropriate English rendering. Class 5 constitutes the basis of very close pruning, such as that which M. Grin, of Chartres, practises, and is also the end and aim of established orchard-house training. This class is common on the two and three-year-old wood, and indicates both fertility and health in the tree. Under all forms of cordon training Peach trees this type is abundant. Together with No. 7 it should in orchard-houses form the greatest portion of the fruit-bearing shoots. In the case of a Downton Nectarine bush which had been about eight years in a pot in my orchard-house, out of 120 fruitful shoots no less than 110 were of Classes 5 and 7. The blossom-buds almost all set in clusters of four or five, requiring to be thinned down to one fine specimen. All writers agree that this class of shoot should not be meddled with or pruned in any way; neither should it ever be rubbed off, no matter where it occurs. It is a perfect type, and will reproduce itself by means of its terminal leaf-bud, besides maturing the finest fruit. At the ensuing season it may present the appearance of

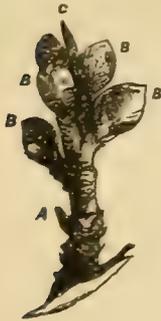

Fig. 5.

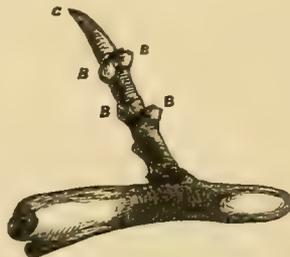

Fig. 6.

6. THE FRUIT SPUR AFTER BEARING (fig. 6).—This is one of the types of perfect shoots which have been added to M. Dubreuil's classification. It has, therefore, no French synonymous name; nevertheless, it is of a sufficiently distinctive character and appearance to warrant a separate notice. To orchard-house pruners especially it will be welcome, as it is occasionally difficult to treat. The reason is that the specimen here drawn from nature is of a slender form, and the blossom-buds at *B* have evidently fallen off without setting, which shows a want of vitality in the tree. A shorter and more sturdy form, then, might have been chosen to represent the class, and then it would probably have appeared where the fruit had been attached. This one has not elongated much, the leaf-bud *C* marks its extreme development; at the same time it is on the point of extension, and will by the end of the summer remain a short bearing cluster shoot, all the portion below *C* being, however, bare ever afterwards. It is certainly a good class of shoot, and should not be suppressed in orchard-house pruning, and rarely, unless a foreright, in out-door work. It will not grow strongly in any case and is, therefore, valuable for bearing next season. It has but the single defect of an inch of unfruitful wood. Not to notice it would be to leave amateurs in ignorance of what the numerous "clusters" look like after the season is over.

7. THE FRUIT SPRAY (fig. 7).—This class is included by Dubreuil under the head of "proper fruit shoots," which he says are "from 4 inches" in length; but from other specimens which were photographed for this work, and which were taken from strong-growing trees, it was seen how this type passes, like the others, into Class No. 2 whenever the blossom-buds are arranged in groups with a leaf-bud between them. It is the fact of the single blossom-buds, in which No. 6 alone participates, which marks the distinctive character of this beautiful class. 8 also has only single blossom-buds, but it has no terminal leaf-bud, which No. 7 has; 7 has, therefore, been promoted to the honour of being a separate type, and it occurs very frequently on healthy and well-managed trees, both in-doors and in the open air. This class having a terminal leaf-bud will, besides bearing, extend, and having sometimes a latent bud at the base may, by judicious summer-stopping, become double, in which case generally shoots of the same character will be formed. This is a valuable disposition in this class, and for many reasons it should be retained instead of being suppressed, as it often is. 5 and 7 are essentially orchard-house shoots, being developed more readily under the somewhat artificial treatment therein practised.

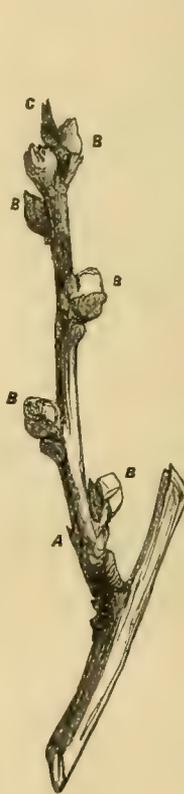

Fig. 7.

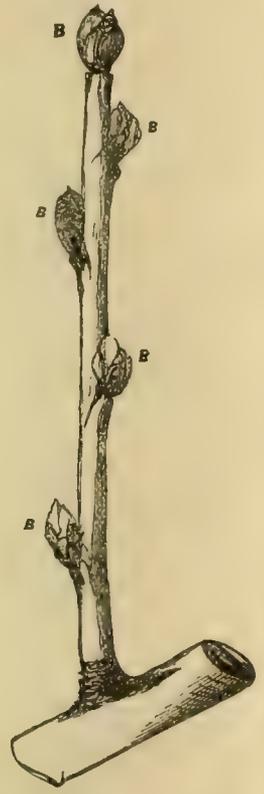

Fig. 8.

8. BARREN SPRAY. *Chiffon* of Dubreuil (fig. 8).—An unsatisfactory class, indicating neglect or a bad habit of the tree itself. There is much difference of opinion among long-pruners how to treat this class, but if retained they should be cut to above the lowest fruit-bud. They occur in orchard-house bush trees frequently, and show defective pruning, because by stopping they would probably have passed into some other type, or, at the worst, dried up entirely. When very injudiciously managed a bush tree may soon become crowded with them, some being much longer than the specimen selected, and others having a bare portion below them. All this arises from neglecting to observe that there is no terminal leaf-bud, so that the shoot is blind.

These eight classes of shoots are all that we may look to find in ordinary cases. Wherever there seems any variation

from them it is because they are passing into another form ; but even this can be readily recognised, and need not cause any perplexity. 1 and 4 are the only pure wood shoots, for the others are more or less all fruit-bearing. It is to be hoped that rules for pruning are simplified by means of this classification. All may not be of one mind as to these rules, but the general principles here laid down were, of course,

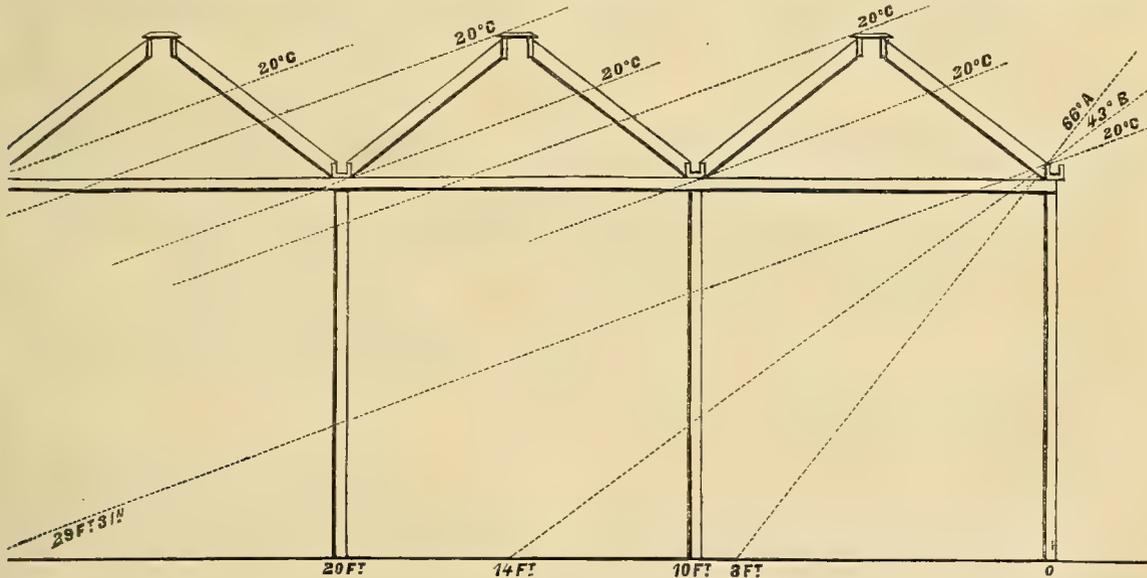

the first thing requiring to be settled. It may be added here, that perhaps the very best modern authorities on these matters have given their approval to this arrangement of the shoots. One great difficulty was to render appropriately the names by which some are known on the continent ; another was the want of precision in the current horticultural terms.—T. C. BRÉHAUT, *Richmond House, Guernsey.*

CONSTRUCTION OF A PINE STOVE.—No. 3.

HAVING, as I think, shown that the atmospheric heat required to ripen Pines in winter cannot be maintained in narrow span-roofed houses without employing such a large surface of piping as must materially injure the plants, I shall leave the further consideration of this shape with the remark—that our desire should be to adapt the house to the use for which it is required ; and that, though this shape is not fitted for winter forcing, it may still be admirably adapted for summer orchard-houses. In winter our only source of heat is hot water, and we require economy in its use as much for the health of the plants as on account of the cost of production. In our fear of losing it we build brick sides to our houses, thereby suffering loss of light, for which nothing compensates. Can we not build better, that is, lighter, houses without losing heat ?

Mr. Speechly, writing in 1790, says—"The sun is the primary cause—the very life and soul—of vegetation." He

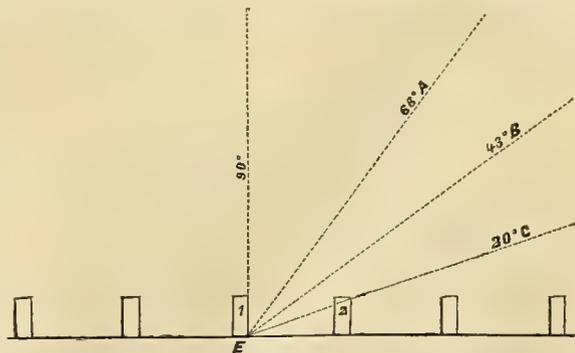

also tells us—"In Holland it is customary to begin to force Vines in November, in order to have ripe Grapes early in the spring. In these frames, used for winter forcing, it is found necessary that the glass frames should be in an almost perpendicular direction. They are about 5 feet wide at the bottom, and at the top about 3 feet ; the height of the Vine wall, to which the frame is affixed, about 10 feet." I therefore propose to make the sides of my house 10 feet high. The advantage of this increases as the angle of the sun's rays decreases, the direct sunlight shining so much further down the house, particularly from the south and west sides. Plan No. 6 will show this. Mr. Speechly says—"The angle of the sun's rays at the equinox is 43°." I have taken this as a basis. At midsummer the sun is 23° north, making its altitude 66° ; in winter 23° south of the equator, making it 20°. In this I may be wrong ; but it is the principle I wish to show, and it will serve for this purpose.

PLAN No. 6.

I do not know any plan that will better tend to increase the light during our dark months ; and I think that double glazing will enable me to retain the heat. Certainly 10 feet of double glazing will not cost more than 5 feet of brick wall. I would have the inner portion made so that it could be taken down as soon as the March winds were over, merely employing it as a means of preventing what I may call too much unauthorised ventilation ; but some may say, You leave out the roof ; can you get more light through the sides ? Let us turn again to Mr. Speechly—"Vineries are sometimes built on commodious plans, of which the most elegant certainly are those which have an entire glass-framed roof, with one side descending to the east, the other to the west ; the south end must consequently be glazed. But as these buildings admit of the meridian sun only at the end of the house, they are very improper for producing Grapes at an early season." From this extract I should presume Mr. Speechly intended to mean a house that had no sides. Let us treat it as such. He says the roofs descend to the east and west. In this case, when the sun was in the south its rays would fall on the rafters, as represented

in Plan No. 5, at D and E, on rafters 1 and 2. I intend running my roofs east and west, so that when the sun is in

PLAN No. 5.

the south it will be as shown in Plan No. 6. To avoid con-

fusion I have only carried out the lines c, as I am considering the case of a house in winter; and here you will see, when the sun is in the east or west, it will still be, as shown in Plan No. 5, which I consider Mr. Speechly was justified in calling improper. May we not all confess he was very wise in his generation? I have been as much surprised as pleased in reading his book, and shall set great store by it.—G. H.

#### EARTH A DEODORISER OF SEWAGE.

My attention has been directed to two letters in your Journal signed "UPWARDS AND ONWARDS," in which the writer gives much, and to some extent merited, praise to a pamphlet by Mr. Wilmot on the dry treatment of excrementitious matter. In asserting, however, that ashes are a better material for the purpose than dry earth, he has, together with Mr. Wilmot, fallen into a great error. I shall feel, therefore, greatly obliged if, as the advocate of the dry earth system, whose observations and experiments have extended now through many years, I may be allowed space in your Journal for a few words on the subject. It is so long ago as the year 1857 that I discovered that very important property of dry earth or clay, of which Mr. Wilmot makes no account whatever—viz., its capability of repeated use. I will limit my remarks to his two objections to my system. Firstly, that I recommend the use of a mechanical application of earth; and secondly, that I use earth and not ashes as the medium of removal.

Now, with regard to the first of these objections, there is no greater necessity for the use of mechanical arrangements for the supply of earth than for the supply of ashes: indeed my pamphlets indicate the simplest possible mode of applying the earth without any machinery. Almost as soon as I began to carry out this mode myself I perceived certain obvious advantages which would arise from some mechanical contrivance—advantages (I might almost say necessities), if the system should ever be adopted, as I am confident that sooner or later it will be adopted, in towns, inside houses, and in upper stories of houses—advantages in economising the use of earth, both as to smallness of the quantity to be used, and especially in the cases of schools, gaols, and asylums, and as to the certainty of its application. In conjunction, therefore, with Messrs. White & Co. I contrived, and have patented some very simple contrivances for this purpose; and although Mr. Wilmot may have seen and heard of one or two failures, as he asserts, arising from defective manufacture, those advantages of which I speak can be, and are, by mechanical contrivances secured. Without some such contrivance it is sufficient to observe that a closet is exactly what a water-closet would be without a mechanism for applying the water.

Second, as to Mr. Wilmot's other objection to the use of earth and his preference of coal ashes, I venture to pronounce it simply absurd. From the very first I have regarded my system as one not for England only, but suited to all countries; and, as I have stated in my third edition of "National Health and Wealth," it is already very generally adopted in the gaols and barracks of British India. Where will Mr. Wilmot find his coal ashes there? Where will he obtain them on the continent of Europe? And even if during the winter months in England there should be an adequate supply, what cottage or what moderately-sized house will supply enough for a large family during the summer?

The most decided objection, however, to the use of ashes is that which Mr. Wilmot himself acknowledges—viz., that the mass of excrement with ashes becomes foul and gives off a bad smell. How then can they be said to be equal in deodorising power to dry earth or clay? The truth is that ashes from their alkaline character exert a chemical action on the nitrogenous matters of this mixture, and generate, an analogous process to that of fermentation, without absorbing the gases generated; whilst, on the other hand, dry earth, from its well-known capability of absorbing manurial compounds, takes up into itself any gaseous products which through its mixture with foul substances may have been eliminated. Such mixture will give off no smell and is perfectly harmless. If the mixing, moreover, be intimately done all offensive appearance, as well as offensive smell,

vanishes, and if in that state it be allowed to dry it may be used with equal efficacy the tenth time.—HENRY MOULE, *Fordington Vicarage.*

#### PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

CYPRIPEDIUM LEVIGATUM (Glossy-leaved Lady's Slipper). *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Diandria.—Discovered by Mr. J. G. Veitch in the Philippine Islands. Flowers yellow, variously streaked with purple.—(*Bot. Mag.*, t. 5508.)

ARUM PALESTINUM (Jerusalem Arum). *Nat. ord.*, Aroideæ. *Linn.*, Monœcia Monandria.—Procured from near Jerusalem by Messrs. Veitch. Spathe inside and spadix dark purple.—(*Ibid.*, t. 5509.)

RAPHIOLEPIS JAPONICA var. INTEGEREMA (Entire-leaved Japanese Raphiolepis). *Nat. ord.*, Rosaceæ. *Linn.*, Icosandria Digynia.—Native of Japan, &c. Flowers white and sweet-smelling.—(*Ibid.*, t. 5510.)

HYPOSTES SANGUINOLENTA (Blood-veined Hyposstes). *Nat. ord.*, Acanthaceæ. *Linn.*, Diandria Monogynia.—Introduced by Messrs. Veitch, it is believed, from Madagascar. Flowers pale purple; leaves dark green, veined with pale purple.—(*Ibid.*, t. 5511.)

AUCUBA JAPONICA (Japanese Aucuba).—Noticed at p. 361.—(*Ibid.*, t. 5512.)

ODONTOGLOSSUM PESCATOREI var. SPLENDENS.—White spotted with purple. Received a first-class certificate from the Royal Horticultural Society's Floral Committee.—(*Floral Mag.*, pl. 241.)

CAMELLIA *Contessa di Gonda*.—Delicate pink, with darker stripes of the same colour. At Mr. Bull's Nursery.—(*Ibid.*, pl. 242.)

HYACINTH *Thorwaldsen*.—Exhibited by Mr. Cutbush, Highgate Nursery. Pale blue, lobes with darker centre.—(*Ibid.*, pl. 243.)

CLARKIA INTEGRIPETALA FLORE PLENO (Double Entire-petalled Clarkia).—Flowers double, rosy crimson. Possessed by Messrs. Carter, Holborn. Handsome flower.—(*Ibid.*, pl. 244.)

ACHIMENES.—*Rose Queen*, purple. *Aurora*, scarlet. *Stella*, mauve. The two first-named had first-class certificates, and the third a second-class certificate from the Floral Committee. They were raised by Mr. A. Parsons, gardener to W. J. Blake, Esq., Danesbury, Welwyn.—(*Florist and Pomologist*, iii., 89.)

#### THE PLEASURE-GROUNDS OF PARIS.

THE Botanic Gardens, like many other venerable places, have been preserved with great expense, as an illustration of the ease and tranquillity with which public business was executed in old times. Add to these the gardens of the Luxembourg and Tuileries, all three of which have lately undergone some improvements, and we have the gardens of Paris as furnished by the State. On the arrival of the Emperor in 1852, knowing the useful effect of transforming the many resorts of vagabonds and strongholds of revolution, he determined to embellish the city, improve its health, and give employment to the dangerous, if not working, thousands of the Parisian populace; losing no time, he appointed Baron Haussman, as prefect, to direct and carry out his plans. He proposed the improvements for the consideration and sanction of the municipal council, and ordered that the money received at the octrois, which amounts to about 180,000 francs per day, should be expended for this purpose; he appointed a staff of officers to conduct, and assistants in every branch capable of directing, the practical operations. The result is incredible: it surpasses even his own anticipations. Never have such improvements been effected in the same time in any other city in the world. Parks, promenades, gardens, lakes, fountains, bridges, temples, and boulevards of unequalled beauty, have sprung up on the very spots where imagination would have called them, to replace those retreats of sickness and filth—those dens of vice and crime.

Wherever the Emperor has gathered his notions of boule-

wards, there can be no doubt but those on gardening are of English extraction, as may be traced in his first grand design—Bois de Boulogne, the most extensive, beautiful, and best designed of all the fashionable promenades of Paris: though without the fortified boundary between Auteuil and Neuilly it is certain, at no distant day, to be included within the limits of Paris.

Passing the Tuileries, crossing the Place de la Concorde, where we must not stop to contemplate its inimitable beauties, nor dwell too long on the different phases in which history will represent it to us, and quickly going along the grand avenue of Champs Elysées, every step of which presents some fresh beauties, we find some well-designed plots filled with rare plants in out-door culture, such as *Erythrina ruberrima*, *Ficus elastica*, *Wigandia urens* and *caracasana*, *Nicotiana wigandioides*, *Begonia fuchsoides*, *Aralia papyrifera*, *Caladium odoratum* and *esculentum*, *Musa rosacea*, *Coleus marmoratus*, *Andropogon formosus* and *halepensis*, *Canna zebrina*, *hybrida*, *Solanum marginatum*, *robustum*, and *capsicastrum*, &c. On arriving at the Arc de Triomphe, that masterpiece of art, we stand in the centre of a circle which terminates the avenue, and from which radiate twelve avenues, such as are only to be found here. From here, ten, fifteen, or twenty minutes will suffice to conduct us to the following entrances of Bois de Boulogne:—Portes Maillot, Sablons, Dauphine, and Grille de la Muette. Arc de Triomphe once passed, we see, opening in front, a little to the right, three broad avenues; to the left the Avenue of St. Cloud, formerly Avenue of Charles X.; between this and the route to Neuilly lies the Avenue de l'Impératrice, attracting the attention by its grandeur and animation, and by the beautiful landscape with which it is surrounded and terminated. This avenue, which is the most direct from the Tuileries, was opened in 1855; its length is nearly a mile, width about 110 yards, comprising a central road for carriages of 17½ yards wide, an alley on either side of 13 yards, one for pedestrians, and the other for horsemen, with two belts of grass of about 30 yards each, in which have been planted some fine groups of Coniferae, &c., also some beds filled in the summer months with the choicest plants; finally there are two lateral roads of nearly 9 yards each for the service of the neighbouring proprietors: these are enclosed by a very rich railing of one uniform model. No habitation can be constructed at a distance of less than 12 yards from the railing. On passing along this avenue we perceive, towering sternly above the Bois de Boulogne, Mont Valerien, one of those formidable forts which were constructed by Louis Philippe, while a little to the left may also be seen the ridge of St. Cloud, Bellevue, and Meudon.

We now enter Porte Dauphine, which, although not so large as the Grille de la Muette, and deformed a little by the appearance of the fortifications, though hidden as much as possible by trees and shrubs, is, nevertheless, a most elegant and richly ornamented entrance. This once passed, we find ourselves in the Bois de Boulogne, surrounded as it is by villages and castles, most of which recall a great number of historic events and literary anecdotes. In the early times of the French monarchy this formed part of the ancient forest of Rouvray, taking its name from the *Quercus robur*, which at that time was the predominant wood here.

It also appears that at that period Passy, Auteuil, St. Cloud, and Meudon, were comprised in this forest of sessile-fruited Oaks, which seems to have been inhabited for the first time towards the end of the sixth century, a few huts having been erected by the peasants along the sunny banks of the Seine; and they afterwards succeeded in clearing some of those virgin wastes, and there planted the Vine. The name given to this small assemblage of cabins was Nijou (in Latin Nimeo). At a later period the extensive wilds which surrounded the village of Nijou were enclosed, and keepers were placed there to feed and protect the game. At this time the modern Bois de Boulogne received the name of Rémise du Roi. About the fourteenth century this wood became the resort of robbers and adventurers. So infested had it been that the convoy sent by Charles V., with the baggage of Duguesclin, was here attacked and pillaged in open day.

Louis II. gave the forest of Rouvray to, and therein erected a mansion for, his physician, James Cottier, but of this the parliament stripped him on the decease of the king. It was about this time that the name Bois de

Boulogne seems to have been given to a portion of it. Afterwards Francis I., passionately fond of sport, appropriated it to game, and built the castle of Madrid, where Henry II. gave brilliant fêtes. Charles IX. constructed, in his turn, a residence, which has since received the name of Castle de la Muette, in which he used to reside in the hunting season; it was afterwards frequented by Louis XIII., but Louis XIV. abandoned it for Versailles. It became again the haunt of the profligate Louis XV., who greatly improved it. In the beginning of the eighteenth century the Regent embellished La Muette, which became the favourite resort of his sister, the Duchesse de Berri. In this castle Marie Antoinette slept on her arrival at Paris, in awaiting the preparation of the Tuileries. It was at this place, also, towards the end of the eighteenth century, that the first horserace was run in France; and it was here the first balloon experiments were made by Pilatre du Rosier, who made an ascent accompanied by the Marquis d'Arland. But the revolution dispersed the aristocracy and literati, which then peopled the environs of the Bois de Boulogne.

Napoleon I., wishing to develop its natural beauties, commenced a grand project, but his intentions were frustrated by the belligerent visit of English, Russian, and Prussian armies. At the second invasion the English army encamped here, and cut down, burned, and built their tents with Oaks which Francis I. had planted. Their camp extended from Ranelagh to Porte Maillot. The Russians and Prussians did the same at different other points, so that when the allies retired the Bois de Boulogne presented a sort of waste, covered with débris and ashes. A few trees near the cross of Catelan and Porte Maillot alone escaped the destroying hand of these unwelcome visitors. Louis XVIII. did all he could to efface the too glaring traces of these lamentable disasters, and replanted it, and Napoleon III., for reasons already cited, and from his long sojourn in England, knowing the importance of public gardens, determined, in the beginning of 1852, on giving to Paris one of those public promenades which are the pleasure and pride of London.

From 1848 to 1852 Bois de Boulogne formed part of the State demesnes. By an Imperial decree of the 2nd June, 1852, it was ceded to the city on the following conditions:—

- 1st. To defray all expenses.
- 2nd. To expend within four years £80,000 in its embellishment, and to submit to the Government the plan before executing it.
- 3rdly. To preserve for the purpose intended the lands conceded.

Hardly was this decree made known when the city took possession, and commenced the work. The laying out was given to an able landscape gardener, M. Varé, who, acting on the indications and ideas given him by the Emperor, traced out a plan which was adopted without any modifications, and at the completion of the work meritoriously received the "ribbon" from the hands of the Emperor.

M. Varé has since been replaced by an engineer, M. Alphand, and a head gardener, M. Barillet, to whom are entrusted the management and formation of all the public gardens of the city of Paris, and by whom have been formed the numerous minor gardens which adorn this capital, none of which, however beautiful, as yet make any approach to the Bois de Boulogne.

There is at this moment in course of formation the vast Forest of Vincennes, which, though in extent, fertility of soil, and magnificence of its trees, far surpassing Bois de Boulogne, still is, owing to its position, never likely to become a favourite place for the fashionable aristocracy. Charenton and Butte de Montmartre are undergoing similar transformations. Bois de Boulogne has cost many thousands and many years, but it is a lasting monument, and will long stand at the head of works of this sort.

The principle said to have been applied here was to take a little from all, without destroying any. Wherever existing obstructions worth preserving came in the way, the visitor has been sent gracefully round. In this way many fine old trees have been spared from the woodman's axe, while no one will contest the charms given to this picturesque place by the preservation of the tower of the ancient and famous monastery of Longchamp and its neighbouring windmill. The Cross of Catelan, associated with dark tragical remembrances, stands facing one of the entrances to the

garden Prés Catelan, which has been devoted to many kinds of attractive amusement; from 1855 till 1859 it was the scene of theatrical displays, for which a kind of rustic, uncovered theatre was constructed, where all the charms of flowers were more advantageously shown by the aid of skilfully arranged lustres. This has since been replaced by the Concert Musard, in addition to which several military bands play here two or three times a-week in summer.

The name "Catelan" is given it from an event which occurred here in the reign of Philippe le Bel. Catelan was one of the most celebrated troubadours of his time, attached to the court of Beatrice de Savoie, wife of the last Raymond Beranger, Comte de Provence; his reputation became so great that Philippe demanded, as a favour from Beatrice, to send him to his court. On his arrival at the Tuileries, Catelan, not finding the king, who in the meantime had retired to Poissy, was obliged to follow him thither. Philippe, fearing the danger of allowing Catelan to traverse the forest of Rouvray alone, despatched an escort of his guard to meet and conduct him. But Catelan, having unfortunately spoken of the rich present which Beatrice entrusted him with for the king, the chief of the escort assassinated him on the spot where now stands the pyramidal monument. But the chief, on opening the small coffer in which the supposed treasure lay, to his great consternation only found therein a little bottle of some new perfume. The chief returned to Poissy, and told the king he had not seen Catelan; but in a short time after, on his appearing at court, he was detected from having on him the perfume entrusted to Catelan, and was sent to the guillotine.—WILLIAM KELLY, *Au Fleuriste de Paris, a la Muette, Passy, Paris.*—(*Irish Farmers' Gazette.*)

(To be continued.)

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

THE weather is now very favourable for carrying on the various operations of planting and sowing. When any main crops have failed, more seed should be immediately sown. Where they have partially failed procure plants, if possible, to fill up. Now is the time to destroy slugs; late at night and early in the morning they leave their hiding places, and may be destroyed by thousands with quicklime, which should be strewn over every part of the garden several evenings or mornings in succession—in the morning by three or four o'clock, and at night not before nine. By persevering a short time a garden may be entirely cleared of this pest. *Beet*, thin the plants to a foot apart while they are small, fill up vacancies with those that are drawn out, they will produce plants equally good with the others. If the first crop has altogether failed, it is not yet too late to sow another. *Broccoli*, make another sowing of both early and late sorts, the former to come in in October and November, the latter late in the spring. *Cabbage*, earth-up those that were planted early in the spring; tie up the leaves of a few of the most forward of the autumn-planted, to cause them to form hearts for early use. *Capsicums*, plant them out on a warm rich border, water them during dry weather throughout the season. *Chervil*, make another sowing, and also of American Cress. *Celery*, continue to prick out seedling plants. In planting out a second time, before finally transplanting into trenches, make a bed about 4 inches thick, of equal parts of rotten dung and loam on a piece of hard ground, so that at the time of planting the whole of the earth may adhere to the roots after the spade is passed between each of the plants. *Cucumbers*, particular attention is required to keep the plants in a bearing state. Stopping the shoots is the most important point to be attended to, the plants to be looked over every fine morning about an hour after the frames have been uncovered and the plants have had a little air. *Endive*, sow a little seed for an early crop, it is useless to sow much as it will soon run to seed. *Kidney Beans* sown in pots or boxes, plant out on a warm border in rows 2½ feet apart. Another sowing should also be made. *Leeks*, make a sowing to plant out for winter use. *Lettuce*, plant out a few about once a-week, thin the plants in the early seed-bed to a foot apart, and if any were sown on the Asparagus-beds they will require the same attention. *Mushrooms*, woodlice are generally troublesome about the beds at this season, the

best traps to catch them are boiled Potatoes put into a flower-pot and covered with a small piece of moss, the pot to be then placed on its side, by examining it every morning and emptying the live stock into some hot water, their numbers may in a short time be considerably diminished. *Onions*, the weather is now favourable for planting out some of the autumn sowing. Avoid covering any portion of the bulb. *Potatoes*, earth-up the early crops, and those which have just made their appearance above ground to have the hoe run between the rows to keep down weeds. *Scarlet Runners*, the sowings of these and of *Haricot Beans* should be attended to without delay. Thin out seedling crops while the plants are small, and if it should be necessary to stand amongst them, let the soil be afterwards loosened-up where it is trodden.

### FRUIT GARDEN.

Espalier fruit trees demand prompt and peculiar care at this season, favoured by the weather a rapid and healthy growth has been encouraged. The removal of superfluous shoots may now be effected with propriety. Peach, Apricot, Plum, and Pear trees alike require frequent attention. Much advantage may be gained by judiciously stopping some and favouring the extension of others, by the removal of unnecessary shoots and those too close together. Persevere in the destruction of insects on fruit trees, in order to afford the young shoots a fair chance of making healthy growth.

### FLOWER GARDEN.

Now is the time to establish a firm and even sward or lawn, the pride of British gardens; the roller and the scythe will be in frequent request, and much labour is involved in these operations properly carried out. See that the edgings hitherto neglected are put in order for the summer, do not edge beyond the original boundary, and keep the walks filled with gravel. Let the roller be passed frequently along the edges, in order to level them down to the walk; this takes away the harshness of the outline. See that all Rose trees have due attention as to disbudding, stopping, &c. Watch the buds inserted last season, rub off those on the stock in a progressive way, and let all Roses, whether standard or dwarf, be well top-dressed with good rotten manure, if not already done. Where Roses are infested with the grub it will be necessary to go over the plants frequently to destroy this pest. Green fly is also very troublesome at this season, a good washing with the garden engine on two or three successive evenings will greatly assist in getting rid of these destructive pests. In this department the next few weeks will be devoted to filling up the flower-garden beds and clumps intended for the summer and autumn display, and now a change has taken place in the weather every exertion should be made to get the planting-out completed with all possible dispatch. As Crocuses and other bulbs will now be nearly over, patches of biennials which have stood the winter may be placed close beside them. Select a shady border and give it a good dressing of rotten dung or leaf mould, slightly forked in, for planting with the runners of the different kinds of Violets for forcing. The Neapolitan is the best for frames or pots, and the runners will now be found in a proper state for removal. Plant them 8 or 10 inches apart, water them abundantly in dry weather, and pinch off the runners as they appear. If the soil is rich and open they will grow into stout bushy plants by the autumn, and may then either be potted or planted in pits for forcing.

### GREENHOUSE AND CONSERVATORY.

As the New Holland plants go out of bloom their seed-pods should be picked off, the shoots cut back and arranged in the form most favourable to secure compact growth, placing them in an airy part of the greenhouse until they fairly start into growth. When the buds have fairly started will be the proper time for shifting such as require more pot-room, as they can then be kept somewhat close for a fortnight to encourage free root-action without incurring the risk of the buds breaking scantily. Look well to the stock of plants for summer and autumn decoration, and do not allow them to sustain any check through want of pot-room or carelessness in watering. Fuchsias for late bloom must not be kept too warm, but should be placed in a moist shady house, where they will grow much more freely than in a high temperature.

STOVE.

The plants in this house will now be growing freely, and will require frequent attention as regards stopping and training. Give them a proper amount of pot-room, and afford them all the sunshine they will bear without scorching, with a moist atmosphere, admitting air freely on mild days; also afford them sufficient space for the perfect development of their foliage. Go over creepers frequently, so as to regulate their growth and prevent confusion, which, without attention, soon happens. Syringe and shut up early on the afternoons of fine bright days, and be as sparing as possible in the use of artificial heat.—W. KEANE.

DOINGS OF THE LAST WEEK.

DELIGHTFUL warm showers have set all vegetation rapidly growing, and the change on the pastures and corn fields, as well as on most garden crops, is astonishing. It will give a nice help to Strawberry plants now coming into bloom, and as for mowing, a man can do double what he could do in a dewless morning, and the ground too hard and dry for even a roller to squeeze down the little worm and other heaps.

KITCHEN GARDEN.

Very much the same as in previous weeks. Gave a little salt to Asparagus and Sea-kale. Sowed more Turnips, Peas, and Beans. Planted out Scarlet Runners. Pricked-out a lot of Onions sown late in autumn, to yield large bulbs before those sown in spring. Planted more Cauliflower; sowed successions of Lettuces, Onions for salads, Cabbage for summer, &c. Potted Chilis, Capsicums, Tomatoes, thinned out leaves, and some shoots of Cucumbers. Dug up Potatoes in frames, and placed the tubers in dry earth for use. Cleared off the soil, and some 18 inches of the tree leaves that were beneath it. Stirred up what was left and added fresh litter and short grass, so mixing that the grass would give moisture enough to the litter, and thus keep on for a long time the process of combustion; then replaced the leaves, making a bank back and front for the frames to rest on, and filled at once with soil for Cucumbers and Melons. These beds will last for a long time, and when the soil is removed and the bed forked-up they will do for cuttings late in autumn. A little practice enables us with such a rough system to avoid over-heating and great changes of heat and cold.

*Mushrooms.*—We have just spawned our last piece in-doors on an elevated platform. At this season, do what we will, the woodlice will annoy us inside the shed-house, and especially if the bed is made on the floor; if on the shelves, we are much less troubled with them. Even after scalding and trapping numbers of them, we have been obliged to set pots and hand-lights firmly over good patches, if we did not wish to see them holed and scraped in the morning. We are scarcely ever troubled with them during the winter months. We generally smoke the Mushroom-house with burning sulphur every autumn, and that must leave few alive. No doubt they are introduced along with the fermenting material. We have just made up our first piece in the shed out of doors. The material consisted chiefly of long litter from the stables, with a few droppings and tree leaves for want of something better. This had been thrown together and watered to cause it to ferment. It was turned and watered again, the object being not to waste the straw too much by making it too wet. When used the other day it had settled down into a half-decomposed, dry, cakey material. This was well broken and packed together some 16 inches deep, and ere long an inch of horse-droppings will be spread all over. The advantage of the dryness is, that a little manure water can be given when the bed seems to require more nourishment. Over-dryness will starve the spawn, over-wetness will rot it and cause it to exhaust itself in thickish threads. As instanced the other week, if we had thought of it in time we might have saved some of this trouble. Part of the bed made last season, and which bore in summer and autumn, was left after we had wheeled two parts or more out for manure. We believe the rest would have done well too if we had left it. The material was dry rather than wet. A watering with warm water and a slight covering of rough hay until the weather became warm, has caused the

piece to yield a fine lot of Mushrooms. This instance shows, that if the bed be dry the spawn will not suffer from cold. From about the end of last October, when the house Mushrooms were coming in, this shed-bed had been exposed to the colds of winter, with little or no protection except from wet, and now it is coming quite thick again. This shows the importance of not having the material of the bed too wet, nor yet too hot. Spawn will keep long enough if dry. It is quite a mistake to make so much ado about having it only in the autumn after it has been fresh made. We have had fine beds from spawn kept on a latticed shelf in a dry shed for five years.

FRUIT GARDEN.

Chiefly employed in regulating, topping, thinning, dis-budding, or dis-shooting Peaches, thinning Grapes, arranging and stopping shoots, planting-out Melons, &c. Some wet dull days, as Wednesday, were very suitable for thinning Grapes, and doing other work under glass.

ORNAMENTAL DEPARTMENT.

Besides keeping the conservatory neat, potting stove and greenhouse plants, the chief work has been potting late-struck Verbenas, and other bedding plants; dividing *Dahlias*, and planting them out in a trench in the kitchen garden among light, rich material, to be afterwards moved with good balls, giving a pot, and the shelter of the Peach-house to those that were rather late, if of the best florist kinds. Pricking-out lots of other things in beds, as *Ageratums*, where they could have more room, but more generally turning them out in bunches, so that they may require little trouble in watering until we are ready for them. Hardening-off by pretty full exposure plants in earth-pits, &c., and getting the ground well dug and pulverised, turned and returned for their reception. Did our ground please us, most likely we would have turned lots of things out this week, but we got behind with all this work in spring, and we would prefer delay in planting-out to planting-out in beds not sufficiently stirred and pulverised. Most of our bedding-out plants are growing in temporary beds, where they are without pots, and they will suffer but little in the removal. The ground before the rains was also too dry for us to plant, without sacrificing too much of our water. We expect to have a few plants in their places before this is in print; but as a general rule we have never gained much by planting out before the 18th or the 20th of the month. If planted much sooner here the plants require less or more protection, and we would prefer giving it when they are in earth-pits, and where, from not being in pots, they require but little water to keep them healthy. As a general rule, the bulk of bedding plants will thrive afterwards in proportion to the sunbeams dug down into the soil; and if time can be given, the soil can be well warmed if the heated surface is frequently turned in. The vane pointng so much to the north, makes us also a little cautious.—R. F.

TRADE CATALOGUES RECEIVED.

W. Bull, King's Road Chelsea, London.—Retail List of New, Beautiful, and Rare Plants.  
Groenewegen & Co., Amsterdam.—Catalogue of New and Rare Plants.

COVENT GARDEN MARKET.—MAY 13.

The supply is fair, but not more than equal to the demand. Good dessert Oranges are more scarce. A large cargo of new Potatoes, and of good quality, has arrived from Lisbon. They sell at from 3d. to 5d. per pound. Of old Potatoes, the stock on hand is very heavy. Flowers chiefly consist of Orchids, Pelargoniums, Azaleas, Mignonette, and Roses.

USE OF PUTTY IN GLAZING (A. Q.).—As yet we have found nothing better than good putty for glazing. We have no faith in soft greasy putty for keeping large squares secure. Putty on the other hand that is fresh made, though of good materials, is only fit for patching. If made and sweated a twelvemonth before using it will stand all the better. The only way that we know of for securing good glass is to give a good price. Some people boast of purchasing at five or six farthings a-foot, and then grumble when they have smashes. So far as our own experience goes, most of the cracking of glass proceeds from light glazing, and this is one reason why fixing without putty by means of screws and bits of india rubber, &c., has not hitherto answered well. If loose-screwed the glass will rattle and break, if firmly screwed there is apt to be expansion and breakage. We have had some half-dozen or more squares in an orchard-house cracked this season. They were along the front of the house, a line 12 inches wide, in squares 20 inches long, placed closely end to end. We expect that in time we shall lose the most of the row. Had we merely put a thin card or paper between square and square to allow of expansion, instead of putting them closely end to end, we do not believe that we should have lost one. It is just some of these little matters that are of so much importance, and therefore these few cracked panes may be of use if they prevent others making the same mistake. As to putting the laps, there can be no objection to that, but they so far obscure light, and in an orchard-house would demand extra care in ventilation. If the laps are not more than from one-eighth to one-quarter of an inch, and the glass is put on according to the bend, there will be very little space at the laps, and if the roof is not very flat there will be no great amount of moisture lodged between the laps. We ourselves have had very little breakage from unputted laps. We have seen whole rows cracked from top to bottom of a sash, where the laps had been glazed and pieces of the putty had fallen out. We therefore do not advise this extra expense, unless for houses where a high temperature is wanted. We know a great deal of what light glazing will do. We told a friend last season that he was glazing too tightly, and he says now he has lost a fourth. There are some things about good putty that we cannot make out. Last season some sash-bars got as rough as dried mud, whilst bars beside them were smooth and firm.

CUCUMBER-HOUSE (J. L. S., Cornwall).—We have not the slightest doubt that your Cucumber-house, 6 feet wide, 7 1/2 feet at back, and 4 in front, will answer admirably, and it is much the same as we use; but we have as little doubt that a house 10 or 11 feet wide, with a span roof, and a bed on each side, would answer better, but it would cost more for heating. There is nothing original in your iron trough, 6 inches deep and 2 feet wide, covered with slate, for bottom heat. It would be cheaper, and answer your purpose quite as well, if the trough or tank were 1 or 1 1/2 inch shallower, and even then the water need never come within half an inch of the top. You would need to surround and cover this tank with 3 inches or so of broken bricks, stones, or clinkers; it would then matter little whether you grow your Cucumbers in pots, or in beds in the usual way. Both plans answer well, and from 3 feet in width of soil is quite wide enough for Cucumbers. We seldom give them so much. With such a covering for your tank it will be advisable to have your air-heating pipes a little lower than the tank, so as not to affect the covering of the tank, and for winter work we would advise either two 4-inch pipes, or three 3-inch pipes, for that purpose—in fact, if you contemplated no covering for the glass, we would prefer three 4-inch pipes. It is much against Cucumbers in winter to have the pipes very hot in cold weather. If your house is to put up we would advise you to think of a span. The heating, and the glass and wood, would cost more, but the bricks would cost less. Your proposed house will, however, answer very well. Such a house will not only do for stove plants, but also make a good propagating-house. We heat our pit, of similar size, by two 8-inch pipes below and two above, but there is not enough of heating power above for winter. Round our pipes we pack some rough rubble, and then close gravel, on which we place the soil. We can send moisture among the gravel, &c., when we like by drain tiles set upright. This we consider cheaper and simpler than heating by troughs, but we have nothing to say against trough-heating. We presume you know all about having a moist atmosphere in your house, which may easily be procured from the tanks for top or bottom heat. If your tank had been about 3 feet in width we would have made it do for top and bottom heat. A small saddle-back or conical boiler will do all that is necessary.

LILLIUMS WEAKLY (W. G. Longton).—Your best plan is to keep them growing by watering freely until the leaves begin to turn yellow; then gradually refrain from watering, and keep the bulbs in the pots in a sunny place until the autumn. It requires a strong root of *Lilium giganteum* to throw up a good flower-stem.

FLOWER-GARDEN PLANS (A Young Scotchman).—We do not think that your centre of curves and circles corresponds with the four simpler groups at the sides. We think these four groups would be as well without the central oval. We have no doubt, however, that the whole would look well when planted, and, according to your plan of balancing the outside clumps of the groups, we do not see how you can improve it. The Perilla, in the spaces you mention, would do well if kept low. The alternating with silver and golden-edged *Geraniums* is good. (Ada).—Although there is a roominess round your four circles, 8 and 9, they rather spoil the regularity of your plan. We do not think that planting all the eight beds round the centre the same, with lines of five colours across, will be any improvement; the grass will interrupt all such lines. We would rather pair them, and give each pair a broad band of a contrasting colour. Thus, as yellow will be the outside of the central circle, we would fill two crossed beds with yellow, and broad purple edgings; two with purple, and whitish edgings; two with scarlet, and white edging; and two with blue and pink. Then do as proposed with 6 and 7; but edge 10, 10, wholly with *Lobelia Paxtoniana*, and 11, 11, wholly with *Lobelia speciosa*. This will be much better than breaking up the edging. (Cantianus).—We could not improve upon your plan, or the style in which you have arranged it. We think you would please yourself better if, instead of making your two square groups with a walk between them, you made each group complete in itself. If both groups were planted with similar colours it would look well. Mere variety will not make up for simplicity. Your crossed clumps, now, such as 7 in one square, and 7 in the other, are too far apart. Just take some coloured wafers, and try the following:—Do as you propose with 1, 1, and 5, 5, but balance 8, 8, and 9; 3, 2, and 2, 3; 6, 7, and 7, 6; 4, 4, and so on; then use your own plan, if you like it best.

STOPPING PRELARGONIUMS (W. H. W.).—If they are to bloom in August they must not be stopped after the close of the present month.

TO CORRESPONDENTS.

\*\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

ILFORD HORTICULTURAL COMPANY (J. Curwen).—To secure the allotment of shares you should send 10s. for each share you intend to take addressed, to "The Ilford Horticultural Company, London and Westminster Bank, Lothbury, London." No notice will be taken of any application that does not contain the required remittance.

EARLY PEAR.—Messrs. Sutton, of the Royal Berks Seed Establishment, Reading, inform us that they have made several sowings, in different situations, of each of the new early Peas advertised in THE JOURNAL OF HORTICULTURE, and that they find that "Sutton's Ringleader" came into bloom several days before either of the other new sorts, though all were sown on the same day, and under exactly similar circumstances. From their observations during last season they have confidence that the podding and ripening will be still more in advance of all others.

DISEASED GRAPES (C. W. W.).—They are very much rusted, but some of them are also spotted. The rust, as stated by Mr. Fish in "Doings of Last Week," is usually attributed to the berries being touched with hot hands or head; but we question whether it is not often caused by sudden exposure to cold currents of air. The spot is a gangrene usually caused by the roots being too cold, or having descended deeply into the subsoil.

GREEN FLY ON PEACH TREES (A Subscriber, B. Stokes).—Syringe your Peach trees every other day with tobacco water for a week or so. This should be done early in the morning, or after three in the afternoon. You may always syringe the trees with perfect safety as soon as the fruit is set, providing the tobacco water is not too strong. Use it at the rate of 1 lb. of tobacco to eight gallons of water. If you syringe your trees, say on Monday, Wednesday, and Friday with tobacco water, syringe them on the other three days with clear water. If this is well done we think the trees should be quite clear from these pests in one week. Your plan of dusting the Gooseberry trees is very good, and we often adopt it with good success. We do not think it would have the desired effect on the Peach trees. We do not think the dust would injure either the tree or the fruit. There will be no harm in trying it; if it do no good it can be easily washed off again with the syringe.

INSECT ON VINE (F. R. Reeves).—It is the mealy bug (*Coccus adonidum*), one of the worst of pests. Brush with a very hard brush carefully, so as to leave no part untouched, every stem and branch, after which thoroughly paint them with the following mixture:—Soft soap, 2 lbs.; flowers of sulphur, 2 lbs.; tobacco, 1 lb.; and a wine-glass of spirit of turpentine. Mix the sulphur, turpentine, and soap into a paste with warm water; boil the tobacco for an hour in a covered saucepan in some more water, strain it, mix it with the soapy mixture, and then add enough water to make five gallons. More tender plants can only have their stems and leaves sponged with water at a temperature of 115°, frequently, and so long as a single insect can be detected.

INSECT (H. T.).—The insect, of which you sent a multitude, is the minute *Lepigma finetaria*, which is generally considered to feed upon decaying vegetable matters, and consequently not to be injurious to growing plants. The remarkable habit of assembling in such vast myriads, and in masses, is well known. (Col. H. W. Bunbury).—The beetles sent are the *Othiorhynchus vastator*, a most destructive kind of weevil. The best way to get rid of them is to lay a sheet beneath the trees which they attack, and then wait till after nightfall, when the beetles will have mounted the branches, which must be shaken, when the beetles will fall, and be easily seen on the sheet.—W.

VASES FOR CONSERVATORY (Hazelbourne).—We think your vases for such a place should be from 20 to 25 inches in diameter, and from 3 to 3 1/2 feet high. You will find all kinds in the Marylebone Road, and elsewhere.

**SCALE ON OLEANDER** (*A Donegal Subscriber*).—The leaves sent were much infested with scale. Dissolve half a pound of soft soap in two gallons of hot water, and with this sponge both sides of the leaves, but particularly the under side; and be sure to dislodge the enemy so firmly seated on the sides of the midribs. Use the solution as hot as the hand will bear it. After the plants become dry, syringe them with water at a temperature of 140°, laying the plants on their sides, and turning them, so as to thoroughly wash every part. If the pest still infest the plants, repeat the application at intervals. The blotched condition of the leaves may be due to the plants being kept in too low a temperature, and to an excess of moisture on the leaves, or allowing water to stand or drip upon them in too low a temperature. We suspect that they are not constantly supplied with water at the roots.

**PROPAGATING DUTZIA GRACILIS** (*Quiz*).—Cuttings of the half-ripened shoots, which may be had now from forced plants, each with two or three joints, inserted round the sides of a pot or pan, in a compost of equal parts of loam, leaf mould and sand, will soon root, if placed in a mild hotbed and shaded from sun. Cuttings of similar shoots, taken from plants in the open air, may be inserted in July under a bell-glass in a shady border. Pot them when well rooted, and plunge, in an open situation, in coalashes. They will not bloom to any extent in the following season, however well managed. To obtain blooming plants for another year, good-sized branches should be layered into pots of convenient size, plunged near an old plant, fastening down the shoots with pegs, and covering with an inch of soil. An incision is not necessary, though it will facilitate the process. It should be made below a joint, in an upward direction, and about half through the branch. In autumn the layers may be detached, potted into 4½ or 6-inch pots, according to the size of the plants, and be wintered in a cold frame or sheltered situation, the pots being plunged in ashes. Such will bloom a little in the following spring, if the plants are strong and the shoots well ripened in autumn.

**STRIKING CHRYSANTHEMUM CUTTINGS IN MAY** (*Idem*).—Cuttings struck in 3-inch pots in May will make small plants, which may be transferred to their blooming-pots in July, stopping them at the fifth joint or leaf, and again, if necessary, in the middle of July. If the plants are strong and a late bloom is desired, pot them in 9-inch pots early in August, and stop the plants at the same time. To have a good bloom the plants should be struck earlier.

**DAFNE INDICA CULTURE** (*B. B.*).—It requires the temperature of a greenhouse, a light airy situation, and a compost of turfy peat two-thirds, and loam one-third, with a free admixture of sand. Free drainage, a plentiful supply of water, and a moist soil when growing, but at other times never very wet nor very dry, are what we have found necessary for its cultivation. To induce stiff growth and keep the plants bushy we stop the shoots, or cut them in in spring after blooming, and keep near the glass, and near to the point where air is admitted. Kept at a distance from the glass, in the shade, and in a close part of the house, it grows fast and weakly, and produces few if any flowers.

**GISHURST COMPOUND** (*C. W. L.*).—We do not see how we can improve upon your mode of using Gishurst compound—2 ozs. to the gallon. It is just another instance that what will kill a plant in one case will not kill it in another. Try tobacco smoke or quassia water; 4 ozs. to the gallon is strong enough, and use it with a brush over the insects. Were we to syringe plants with it we would use four or five gallons of water.

**PEAR LEAVES DISEASED** (*A. B., near Chard*).—Your Pear leaves are encrusted with fungi, generally the result of extra feeding and deficient drainage. Perhaps there has been scarcely enough of air in the orchard-house. We attribute the twisted Ross flowers you mention to extra feeding and deficient ventilation in the late sunny weather. A little shade would have been useful.

**SHOWING VEITCH'S PERFECTION PEAS** (*J. B., Yorkshire*).—This Pea usually takes sixteen weeks from the time of sowing to that of furnishing pods well filled with peas. If sown now it would come in about the end of August or beginning of September, varying a fortnight according to the weather. Yorkshire Hero is an excellent Pea, but not equal to Veitch's Perfection for an exhibition table.

**SALVIA SPLENDENS FOR BLOOMING IN AUGUST** (*Idem*).—Pot the plant now from an eight-inch to a twelve-inch pot, using turfy loam, with a little leaf mould, and stop the shoots if thin. Tie-out the shoots regularly as they grow, and water and syringe well to keep down red spider. Give plenty of light, keeping near the glass, and abundance of air. It may bloom in August, but there is no certainty of its doing so, its blooming times being autumn and spring, though it may be had in bloom in August by forwarding in a house. Stop the Geraniums now if thin of shoots, and they will not need stopping again to bloom well in August.

**IMPROVING TREE OF BOWLING GREEN** (*M., Cloughton*).—As the soil is heavy and the grass poor, we recommend it to be sown with Suckling (*Trifolium minus* or *filiforme*), coal ashes to the depth of a quarter of an inch to be sifted over it, and then rolled. A watering with lime water occasionally will drive away worms and improve the turf.

**LILUM GIGANTICUM CULTURE** (*A Poor Irishman*).—We should be afraid to put such a fine bulb of *L. giganteum* out in an exposed situation; the winds would be sure to spoil it if you have not a nice sheltered nook for it. You had better shift it at once into a larger pot or tub. Such a tub as yours should throw up a spike 10 feet high; you may stand it out of doors at once. If you keep it in a pot or tub let it remain in the open air in some sheltered corner till it begins to show flower, when it should be taken into the greenhouse. If you have a sheltered place and wish to plant it out, dig a hole 3 feet deep and 2 feet wide, fill the bottom of the hole with 9 inches or a foot of broken bricks for drainage, on these place a little moss to prevent the soil from getting down amongst the drainage, then place 2 or 3 inches of your prepared soil on the top of the moss. After you have turned your plant out of the pot place it on the hole, and fill the space left around the sides with the soil suitable for Lilliums. This, however, should not be sifted fine, but be used just as it is chopped, in nice pieces of sod about 2 or 3 inches square.

**CHANNEL ISLANDS** (*A. B. C.*).—At Guernsey you could do what you propose; but whether you could pay your man's wages out of the surplus produce of your gardens depends upon circumstances, such as skill, soil, and season. There is but one town on the island, but you had better reside near that for the sake of facilities of shipping produce to England, and other conveniences. You must go and look for yourself.

**TREATMENT OF AZALEA AFTER BLOOMING** (*Adnes*).—As soon as your Azaleas have done blooming place them in a close frame or stove for six weeks, supply them well with water, and syringe them two or three times daily with water. As soon as they have made their new growth put them into a cool frame or pit for a few days. After they have become a little hardened place them in the open air where the direct rays of the sun cannot strike on them. They may remain in this position till the end of September, when they should be taken into a cold pit or greenhouse, but they must not at any time suffer for want of water. The Camellia may be treated in a similar manner, only it will not take quite so long as the Azalea to mature its growth. As soon as you see the young flower-buds formed the plants should be taken at once to a cooler place. If this is not done they will commence their growth again, which will prevent their flowering the following season.

**MANAGEMENT OF DOWNTON NECTARINE** (*G. K., Sevenoaks*).—If your Downton Nectarine was a small tree, such as you would get from a nursery-men, you ought not to have expected any fruit to have remained on it; if any had set it should not have been allowed to remain on the tree the first year after planting. The wood was not ripe, which was the main cause of the young fruit falling off. It is not by any means unusual for the Nectarine tree to set its fruit in clusters in the way you describe, but it would be against all reason to allow them to remain so. They should be cut out with a sharp pair of scissors, leaving but one; this should be left in the best position, where it would not be rubbed by the branches of the tree, and where it would have room to swell to its full size. The best shapen fruit in the cluster should also be left, and not more than from ten to eighteen fruit should be allowed to remain on the tree this year. This should be determined by the strength of the tree.

**PLEROMA ELEGANS LEAVES SCOREED** (*M. C.*).—The hotbed was too close for the *Pleroma elegans*. We should think the rank steam generated in the hotbed spoiled the leaves in the first instance; if the hotbed was kept rather close, and the sun came out strong, it would be sure to have this effect on the leaves. The *Pleroma* should receive similar treatment to the Azalea after blooming, for which see answers to correspondents in this and previous Numbers of the JOURNAL OF HORTICULTURE.

**ZINC LABELS** (*J. Wilson*).—You had better buy a piece of zinc, score it in strips of the size you need by means of an old knife, and write upon them with the ink for which we recently gave the recipe. We will endeavour to publish some notes on the subject next week.

**REMOVING OFFSETS OF ATRICULAS** (*H. B.*).—Rubbing off the offsets will strengthen the plant, but we rather question whether plants which are inclined to throw off offsets will make large trusses. (*G. H.*).—We do not know of any named collection of hardy self Auriculas. The florists' varieties are too tender.

**FOWL MANURE** (*Clematis*).—We have not had much experience with this manure used alone, except seeing it applied to grass land in places adjacent to poultry-houses, and there it is sometimes administered too thickly, and with only an indifferent result. We should not advise it being applied to Strawberries or Raspberries, but for other fruit trees it may be beneficial, and to such plants as Geraniums, which require a stimulating rather than a lasting manure, it may do good; but we think it will be better in all cases to mix it with five or six times its bulk of soil, and apply it as a top-dressing just before rain.

**CREEPERS FOR THE SUNNY SIDE OF A HOUSE** (*Idem*).—If you want a fast grower, plant *Jasminum revolutum*, which has also the property of looking well all the year, as likewise does the Evergreen Honeysuckle, or, better still, the Yellow and White Banksian Roses. Clematises having a shabby look for so long a period, can only be advantageously planted in company with something else. A *Wistaria chinensis* is better, and a *Bignonia capreolata* also quickly occupies a large space. If, however, the space is limited, and the situation good, try *Ceanothus azureus* and *dentatus*, or *Magnolia grandiflora*; or for an exposed one, *Pyracantha* look very well.

**WATER PLANT FOR SMALL POND MADE FOR BEES** (*H. W.*).—*Ranunculus aquatilis* looks as well as anything that merely floats on the water, or if your case be urgent and the water stagnant, get a pailful of *Aponogeton distachyon* (duck's meat), from a neighbouring pond and place in it. *Veronica beccabunga* (Brooklime), also grows freely in pools not too deep, and the same may be said of Water Cresses and many other plants. We expect the place is too small for a Water Lily, but in the absence of any of these we would let something like a basket-lid or two float in the water. It would enable the bees to find a landing place to dry themselves and regain wing.

**ENDIVE** (*H. M. J., Ireland*).—It is a general remark that no one garden in the United Kingdom produces such good vegetables, as a whole, as are sold in Covent Garden. The reason is obvious: years, or rather ages, of practice have found out which locality is best suited for each individual plant, and it is cultivated there. The best Endive we have met with in a growing state was on the banks of the Thames, where manure by the wagonload was applied almost to excess. The Endive was grown on in the autumn as long as it was thought safe to allow it to remain outside, and for early winter use some of it was blanched then; the rest taken up with balls, and placed under glass, where it was protected, and brought into market as required. The only points in its culture differing from that pursued by every one else, is the extra richness of the soil, and the knowledge which the cultivation of, perhaps, only some three or four different articles enables the grower to attain of the details of good cultivation in each, which no private individual, having a number of objects to attend to, can expect to arrive at; besides which, it must be observed that everything sent to the London market is sent when at its best, whereas in private families the article is only sent when wanted, which may sometimes be after it has passed its best, or may not have arrived at it.

**FIG TREE NOT BEARING** (*John Wilson*).—It is likely that your tree wanted more water during the summer and early autumn months of the last and the preceding year, as the Fig seems to require more moisture than any fruit we know of. If you can supply it with liquid manure at times during the summer, it is likely you will have more success hereafter. Perhaps this can be done without disturbing the pavement over the roots. Do not give the liquid manure strong, and at times give plain water instead.

**VINERIES—SALARY** (*Inquirer*).—It is quite impossible to say how many vinerias a gardener could manage, and we know of no instance of a gardener having no other employment. From £75 to £100 a-year would not be too high a salary.

**REMOVING FLOWER-STEMS FROM TULIPS** (*A Subscriber*).—We do not expect any particular good to arise from cutting off the flower-stalk unless it shows symptoms of seeding, when it had better be taken off. Do not take up the bulb until all foliage and flower-stems have quite ripened and died down, as Nature in this, as in most other cases, does her own work best.

**REARING AMARYLLIS FROM SEED** (*G. H.*).—The process is very tedious, and takes at least three years to produce a bulb large enough to flower. It may, however, be accomplished by sowing the seed as soon as it can be had, and allowing it to remain on the surface of the soil for some time

before giving water, when heat and moisture may be applied at the same time, and all during the time the plants seem growing; but when they seem to stop withhold water by degrees, and let the small bulb repose and rest, and remain completely cool and dry for two or three months, when the process of growing on may be repeated. It is possible you may obtain seed from the trade, but it is not at all plentiful.

**NAMES OF PLANTS** (*E. S.*).—Your flowering tree is the Bird Cherry (*Prunus padus*). (*H. R. F.*).—*Carpinus betulus*.

### METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending May 13th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.
			Air.		Earth.				
	Max.	Min.	Max.	Min.	1 ft. deep.	2 ft. deep.			
Sun. 7	29.980	29.889	60	32	56	53½	S.E.	.37	Dry haze; rain; showery; cold at night.
Mon. 8	29.944	29.755	70	46	55	53	N.E.	.12	Slight fog; dry haze; fine; overcast; rain.
Tues. 9	29.592	29.542	72	40	55½	53	S.W.	.73	Foggy; low white clouds; very fine; thunder, lightning, and
Wed. 10	29.493	29.485	52	42	56	53½	N.E.	.60	Rain; showery; constant heavy rain. (heavy rain at night.

### POULTRY, BEE, and HOUSEHOLD CHRONICLE.

#### TAKEN TO COCHINS.

"TAKEN to Cochins!" Well, and how came that about? A devotee to Bantams, the smallest of fowls, to become a keeper of the largest!—a lifelong worshipper, to speak figuratively, of Game, the perfect in symmetry, to fall in love with Cochins, who have no symmetry at all! But 'tis human nature to go from one extreme to another. Rome republican became Rome imperial, and the democratic boy becomes the tory man. A friend six feet two in his shoes was the other day walking round my rectorial domain, and, catching sight of Will Waddle (that is the name of my Cochins cock), exclaimed, "Well, what a monster!" "Yes, but he is so gentle." "Ah! we giants are a gentle race," responded Six-feet-two. "True, so you are."

"Taken to Cochins! And how came that about?" I again exclaim, for it seems odd to myself, as I carry with difficulty in both hands my present feathered pets, for my late ones I only wanted one hand. Well, it came about in this way: I have often wished to keep large fowls since I have resided here; but how was I to manage it with no back yard, and no divisions save of privet and laurel between stable-yard, and kitchen garden, and flower garden? I have frequently puzzled my head, but all in vain. "How can it be done?" I had meditated upon this text, but the fruit of my meditations had been nought. At last a sudden thought struck me—a bright first thought, quite an inspiration; it was Sir Isaac Newton and the apple over again. Why, was there not my pigstye in a corner hidden by my stable? There close by was the manure-heap of course, all screened from view by a well-grown privet hedge, giving an interior some 6 yards square. "I have it," I exclaimed. "I'll take to Cochins; it will be large enough for them inside the hedge." A brief consultation followed with my old man, great at pigs and potatoes, and of whom it is said by the malicious that he is his master's master. I explained to George that as Cochins did not fly, a little wire netting put round the bottom of the hedge would be sufficient; then a low gate. Then the little building used sometimes as an extra pigstye would do for a fowl-house, as they do not perch high, and all would be complete. He approved, entering into my plan warmly. I was charmed with this, for he usually thwarts me, throwing buckets of cold water upon my plans. I guessed the reason of his hearty acquiescence. He felt the Cochins fancy would be good ground on which we should meet to compromise matters, for he lived in daily fear that, in spite of all, I should some day have full-sized fowls running about wherever they liked, and that would break his gardening heart altogether. My Game chickens last summer frightened him; when they grew a little large he said, "Sir, I hae been a thinking them Game vowl make sic a caddle in the garden, that you'd better break off their legs short"—i. e., send them to table. I took the hint, and

sold them immediately. Well, after my new plan had been talked over, off went our coats, and we worked together in the best of humours. We cut the hedge down to 4 feet high, put in several little posts outside, stretched the wire netting from post to post, hung our gate, put up a thick low perch in the desired pigstye, and there was the walk and house quite ready. There was the manure heap, there the cinder ditto, there a clear sunny space; and we looked on, feeling that "in all labour there is profit," and pleasure too. Then said George, "There, now, the vovls 'ull be with the manure, and all the dirty things be together." He could not help being slightly severe. Everything being prepared, a pen of Cochins soon arrived. George grew enthusiastic, having now no fears about his garden; and after a pause (he makes long pauses now and then, and I know something will follow them)—"Now, I ha' been a thinkin that the farmer 'ull let me make a hole through they boards into his field; a little pick o' grass 'ull do um a zight o' good." I asked my good neighbour, best of yeomen and churchwardens, and the request was at once granted. All this happened two months ago; and since that time I have been daily watching the habits of Cochins in a corner formerly avoided, but now full of interest—formerly dull, but now rendered lively, and a source of keen gratification, owing to the presence of fowls.

J. G. Wood somewhere says, "If you want to understand the ways of birds, go and stand or sit out of doors near some trees, remain motionless, and soon the birds will come out all round, just as if you were not there." I have frequently followed his plan with some success. The same plan may be followed, and with far greater success, in regard to fowls. I go and sun myself in my Cochins' yard when my head has grown dizzy with desk work, or I fail in breaking in a refractory sermon—they will be obstinate sometimes, even with tolerably fluent composers—and watch my Cochins. But to return. First, in praise of Cochins, I would notice what has indeed often been remarked upon, but cannot easily be magnified—viz., their great docility. Never once have they attempted to get over my four-foot-high fence, nor even mounted the still lower wall of the pigstye, although it is broad at the top and tempting. On the nest I feed the hen from my fingers. I raise her, she does not resist. I extract an egg or a chicken, she trusts me. Should they walk out of the opened gate, they are most easily driven in—hold up a handkerchief, it is enough. I saw a great number so driven in, and most soberly they returned to their quarters, two and two like a ladies' school,—not an ordinary ladies' school, for there was not a giddy one or a single hoyden among them, but rather a quaker ladies' school of all sober-minded girls. At the same time and place some Bantams had escaped, and how they flew, and resisted, and struggled for the mastery! saying, in spirited Bantam language, "Go in again! No, not if we can possibly help it, that we won't!" Cochins are more like sheep than fowls. You can drive them, and they huddle in a corner and quietly gaze at you. Then, too, with their wonderfully soft fur-like feathers—they are certainly more

like animals than birds. They seem philosophically to say, "We will take life easily whatever happens." When my dog for the first time entered with me, there was not the cackle and strut of other fowls, rather "We should like to be alarmed, but it is not worth while thus to disturb ourselves." A Cochin cock seems to possess (supposing I believed in the transmigration of souls), the spirit of some easy, fat, good-natured fellow. I am sure if Cochins were the only inhabitants of Canada, or people Cochin-like, they would quietly give it up at once to the Yankees. Will Waddle is a good easy soul; if a man he would enjoy nothing so much as sitting in the sun and smoking a long pipe (short pipes imply fidgettiness). He acts upon the motto, "I will not plague myself about trifles, nor meet trouble half way." Wise bird! May I ever be like him.

A word in regard to the appearance of Cochins generally. Most persons on first seeing them exclaim, "How ugly!" But we should remember there are two kinds of taste—the taste natural, and the taste acquired. A child seeing Hamburgs would at once admire them—this is the taste natural—just as all children like water, but have to acquire the taste for beer. But the taste for Cochins has to be acquired. Granted, but this rather adds to the pleasure when acquired, and it is worth acquiring I assure you, good readers. The hen Cochin I hold to be handsomer than the cock. This is singular, as throughout creation (save, ladies, in the case of yourselves), the male is the better-looking of the two—e. g., among beasts, the lion; among birds, the Pheasant; and in poultry, the Cochin cock is the only exception. I like the head of the hen, so sagacious-looking and gentle, not a bit bold. I like to watch her just stepping out, her intelligent-looking head in a listening attitude. The colour of my Cochins is light buff. I should like to have the subject of colour in these birds debated, as the earlier-imported ones are said to have been dark, and I am a stickler for original colour in fowls and Pigeons, as being the purest; though no wonder that a colour so novel and unique in fowls as buff in its many shades should have been so much sought after. The cock Cochin looks best, I fancy, when he is eating; you see then his width of back, and the beautiful tints of his plumage. I find, though my birds have a grass run, that, save in damp and mild weather, they make but little use of it; so unlike energetic Game fowls, who would daily be round and round the four acres. As to laying, we all know their marvellous powers. I have had forty eggs in forty days. "See, another egg, George!" "Yes, sir, they be the best vovls you ever had, and mind you keep 'um." Can we not improve their shape for the table and also their flavour? One friend tells me he always has his Cochins juggled like hare, and that so cooked they are excellent. The flavour of the eggs I think very superior, and the grass (they came from a town), has improved their colour inside and out. The mistress likes them, the cook gets hold of them when she can; but as yet they appear chiefly on the breakfast-table. Improve the shape and taste, what fowl could eclipse them? Surely these are the birds for those to keep who mourn over the number of eggs sent from abroad, and who have little room. Thus I have in all good faith detailed the reason I have taken to Cochins, and my experience with them.—WILTSHIRE RECTOR.

#### YEW TREES POISONOUS TO DUCKS.

WE were made a present of some fine Aylesbury Ducks last year, and one by one they all got swelled crops and died. The person who had the care of them had the last one opened, and found a hard ball of yew leaves collected in the gizzard, which prevented all food passing, and was evidently the cause of its death. There were yew trees hanging over the wall of the yard, just over the water where the Ducks drank, and the leaves falling into the water were swallowed by them, and caused the misfortune. It shows there cannot be too much caution used about these dangerous trees, as their leaves falling into water may affect animals as well as birds.—(H. C., *Kingsfort*, in *Irish Farmer's Gazette*.)

EXHIBITION PENS FOR TURKEYS.—Allow me to announce, for the comfort of any Turkeys who may have suffered from past imprisonments at the Bath and West of England Shows,

that spacious apartments are provided for their accommodation at Hereford. This further extension of liberality on the part of the Society was only agreed to at their last meeting, and though late in the day it is—NEVER TOO LATE TO MEND.

#### A CRY FOR SYMPATHY.

A FEW weeks since "Y. B. A. Z.," or the "Persian" gentleman, expressed his opinion that exhibitors ought to have a little more courtesy shown them. As this fact was indelibly impressed on my own mind, I fully expected that some of your numerous correspondents would echo his sentiments and go more fully into the matter, but have looked in vain for any further remarks on the subject. Since adopting poultry as a hobby my experiences have been painful in the extreme. First, I was foolish enough to suppose that as an exhibitor of a pen of poultry I was entitled to free admission, the same as if I exhibited a fat cow, but I found I must pay my half-crown like the ordinary public. As I find the poultry generally the most attractive part of a show, and very few exhibitors send less than three or four pens, I cannot see the justice of this. On one occasion I had a pen of fowls mis-sent, and did not receive them until nearly a week after the show was over, and had to pay something considerable for carriage. On sending the bill to the Secretary of the show, stating that as the mistake was owing to no fault of mine, I thought the Committee should pay the extra carriage, I did not get even the courtesy of a reply. This recalls to my mind going some sixty miles to London expressly to see a poultry show at the Agricultural Hall, Islington, held in the minor hall at the same time as the dog show. I found that to see the poultry I must pay 5s. to go through the dog show, as there was no other way to see the poultry. Truly, thought I, no wonder they manage better for poultry in France.—BLACK SPANISH.

#### PIGEONS AND ROOKS.

I MUST really beg to differ from our friend "WILTSHIRE RECTOR" as to his opinion respecting the above, expressed in his letter in No. 214. I have on many occasions known Pigeons forsake their abode when they have been placed near a rookery, although their house has been situated in a most comfortable and sheltered spot where neither cat nor rat could possibly have access to disturb them, and it has been attributed solely, and I believe on good grounds, to the proximity of the rookery. I do not for a moment mean to throw a doubt on "WILTSHIRE RECTOR'S" word as to his having kept Pigeons at his own house near a rookery, as there are always exceptions to every rule, but I think that in most cases it will be found that Pigeons have a decided dislike to rooks.

Our friend "WILTSHIRE RECTOR" again remarks that Pigeons will not stay in houses that are placed on the top of a pole. Now, in the southern part of England at various places, and particularly at farms, we often see Pigeons with such a house, and that they breed and live well there. A friend of mine keeps about twenty-five in a similar house, and they do extremely well and are very healthy. I think "WILTSHIRE RECTOR" must allow that if these houses are built well, with roomy compartments, his fears of cats, rats, and draughts may be altogether dispelled; in fact, I am rather partial to these houses, and I think that if any reader is desirous of having one, and have it made, as I suggest, with roomy compartments, he will find that Pigeons stop and thrive very well in them.—HAMBURGH.

#### WILD FOREST FOWLS OF ENGLAND

ARE very little known to the public, but they have been kept for a century in a very remote part of the county of Somerset, adjoining that extensive tract of land known as Exmore Forest, sheltered by an old ruin, and I may say almost unacquainted with man, except the shepherd.

These little fowls weigh 5 lbs. or thereabouts; carriage rather low, somewhat resembling the Partridge; body very round and plump; rose comb, round wattles, and red earlobes; colour pale blue with a shade of ochre; male and

hens both one colour. A few sport from the ordinary colour to black. Their feathers have been tested by the best fishermen and found to be the best for artificial flies, for which purpose these fowls have been kept.

The hens lay about fifty eggs each before they give signs of incubating. I have found them the best of mothers, well adapted to rear Pheasants, being in their habits somewhat similar. I first procured them in the market, where they caught my attention by being all of them of one colour, pale blue shaded with ochre colour. By making inquiries I discovered what I have mentioned in the former part of my letter.—H. LEWORTHY, *Barnstaple*.

#### HENS' NESTS.

It is a common complaint which your correspondent "PERCY CROSS" makes that hens choose other nests than those generally made for them, and with all respect for Mr. Geyelin's ingenuity his proposed plan of using pans will not remedy the evil. Any close receptacle for the nest harbours vermin, which breed to a certain degree in all poultry-houses, and if that is the case the contents of the nests have been a source of irritation to the fowls, and they have sought another nest for themselves. To remedy this annoyance, which too frequently occurs, we produced the "Sanitary nest," which is advertised by us in your columns, and which has given general satisfaction, the orders we have received for them having been repeated in almost every instance. These nests are more particularly intended for laying hens; the nests for sitting hens are at all times best made on the ground, the earth being hollowed out a little to receive the short straw.—E. AND F. CROOK, 5, *Carnaby Street, London*.

#### THE DOMESTIC TURKEY, WITH ITS BREEDING AND MANAGEMENT.

THE following very practical article is from Wilkes' "Spirit of the Times" (American):—

The domestic Turkey can scarcely be said to be divided, like the common fowl, into distinct breeds; although there is, indeed, considerable variation in colour, and also in size. The finest and strongest Turkeys are said to be those of a bronzed black, resembling as closely as possible the original stock; they are reared the most easily, are large, and fatten rapidly. Some Turkeys are of a coppery tint, others of a delicate fawn colour, others parti-coloured, grey and white, and some few of a pure snowy white. All these are considered superior to the black; their colour indicates something like degeneracy of constitution, and they are seldom very large-sized.

To describe the domestic Turkey is superfluous;—the voice of the male, the changing colours of the skin of the head and neck; his proud strut, with expanded tail and lowered wings jarring on the ground; his irascibility, which is readily excited by red or scarlet colours—are points with which all are conversant. Turkey cocks are pugnacious and vindictive, and often ill-treat the hens; they have been known to attack children: and combats between them and the Game cock have taken place, in which the latter was more oppressed by the weight of his antagonist than by gladiatorial skill; in fact the bulky hero has been worsted, as he cannot use his spurs with the address exhibited by the Game cock, which, moreover, fights with method.

The adult Turkey is extremely hardy, and bears the cold of our winter with impunity; during the severest weather, flocks will roost at night upon the branches of tall trees, preferring such accommodation to an in-door dormitory.

The impatience of restraint and restlessness of the Turkey render it unfit company for fowls in their resting-place; in fact the fowl-house is altogether an improper place for these large birds, which require open sheds and high perches, and, altogether as much freedom as is consistent with their safety. Although Turkeys will roost, even during the winter months, on trees, this should by no means be allowed; the feet of the birds are apt to become frozen from such exposure to the air. It must be remembered that the domestic Turkey, hardy as it is when adult, is not equal in point of endurance

to its wild relative, bred in the woods and inured to the elements.

Turkeys are fond of wandering about hedgerows and the borders of fields; they love to visit turnip fields, where, besides the leaves of turnips, which they relish, they find insects, slugs, &c., which they greedily devour.

In the morning they should have a good supply of grain, and after their return from their peregrinations, another feed; by this plan not only will the due return home of the flock be insured, but the birds will be kept in good condition, and ready at any time to be put on fattening diet.

In the choice of birds for stock, care is requisite. The cock should be vigorous, broad in the breast, clean in the legs, with ample wings and a well-developed tail plumage; his eyes should be bright, and the carunculated skin of the neck full and rapid in its changes of colour.

The hen should be like the cock in plumage; those with white feathers appearing amidst the black should be rejected; her figure should be plump, and her actions lively and animated. The hen breeds when a year old, or rather in the spring succeeding that in which she herself left the egg; but she is not in her prime until the age of two or three years, and will continue for two or three years more in full constitutional vigour.

About the middle of March, generally speaking, the female commences laying; she indicates the coming event by a peculiar cry, by strutting about with an air of self-satisfaction, and often by prying into out-of-the-way places, evidently in quest of a secret spot for incubation; for the instinctive dread of the male is not removed by domestication, nor has the male lost that antipathy to the eggs which is his characteristic in a state of nature. She should now be closely watched, and some management is required to induce her to lay in the nest assigned to her. The nest should be prepared of straw and dried leaves; it should be secluded; and to excite her to adopt it, an egg, or piece of chalk cut into the form of an egg, should be placed in it. When her uneasiness to lay is evident, and symptoms prove that she is ready, she should be confined in the shed, barn or place, in which her nest (which should be a wicker basket) is prepared, and let out as soon as the egg is laid. The Turkey hen is a steady sitter; nothing will induce her to leave her nest; indeed, she often requires to be removed to her food, so overpowering is her instinctive affection. The hen should on no account be rashly disturbed, no one except the person to whom she is accustomed, and from whom she receives her food, should be allowed to go near her, and the eggs should not be meddled with.

On about the twenty-sixth day, the chicks leave the eggs, and these, like young fowls, do not require food for several hours. It is useless to cram them, as some do, fearing lest they should starve. When the chicks feel an inclination for food, nature directs them how to pick it up. There is no occasion for alarm if for many hours they content themselves with the warmth of their parent and enjoy her care only; yet some food should be provided for them, and this should be of course suited to their nature and appetite; here, too, let the simplicity of nature be a guide.

The first diet offered to Turkey chicks should consist of eggs boiled hard and finely minced, or curd with bread-crumbs and the green part of onions, parsley, &c., chopped very small and mixed together so as to form a loose, crumbly paste; oatmeal with a little water may also be given. They will require water; but this should be put into a very shallow vessel, so as to insure against the danger of the chicks getting wet. Both the Turkey hen and her chickens should be housed for a few days; they may then, if the weather be fine, be allowed a few hours' liberty during the day, but should a shower threaten, they must be put immediately under shelter. This system must be persevered in for three or four weeks. By this time they will have acquired considerable strength, and will know how to take care of themselves. As they get older, meal and grain may be given more freely. They now begin to search for insects and to dust their growing plumage in the sand. At the age of about two months, or perhaps a little more, the males and females begin to develop their distinctive characteristics.

In the young males, the carunculated skin of the neck and throat, and the horn-like contractile comb on the forehead assume a marked character. This is a critical period.

The system requires a good supply of nutriment, and good housing at night is essential. Some recommend that a few grains of Cayenne pepper, or a little bruised hempseed be mixed with their food. The distinctive sexual marks once fairly established, the young birds lose their names of "chicks," or "chickens," and are termed "Turkey poults." The time of danger is over, and they become independent, and every day stronger and more hardy. They now fare as the rest of the flock, on good and sufficient food.

With respect to the diseases of the Turkey, with them as with all other poultry, prevention is better than cure. The most important rules are, Let the chicks never get wet, and encourage them to eat heartily by giving a good variety of food, yet to beware of injuring the appetite by too much pampering. Taking a pride in them is the great secret of success in the rearing of domestic poultry.—S. M. S.

[We heartily endorse the foregoing. Different climates make different treatments necessary. The hen in our changeable atmosphere should be under her rip for five or six weeks, and for some time after that she should not be let out, if there be heavy dew or white frost. She will start with thirteen poults, through the wet grass, and leave them behind one by one till only three or four remain; she is perfectly satisfied with this remnant of her family, and heeds not the distant and faint cry of those that are perishing in the damp grass. An empty china crate, covered at the top with straw is a good rip for a Turkey hen; it allows her room to move about, and the young ones can be fed in it without their food being taken by the other poultry. A thatched hurdle is a better cover than anything permanent to put over the crate.]

#### PLACING AN ARTIFICIAL SWARM IN A STEWARTON HIVE.

I HAVE just received a Stewarton-hive and I should like to put an artificial swarm into it. I must, I suppose, drive the swarm into a common hive, and having put two boxes of the Stewarton together, all the slides having been removed, dash the bees on the top. There is a bar of wood in each of the boxes to help to support the comb—is it advisable to retain these? I should think the bar in the honey box would be found very inconvenient when cutting out the comb. Is there any objection to dahlias being grown near an apiary? I have heard that there is.—M. S.

[It will be better to leave the driven bees in the common hive until evening, say an hour after sunset, when a cloth may be spread on the ground, on which should be laid two sticks about a foot apart; then with a smart stroke dash out the bees and instantly place the Stewarton-hive over them, resting on the sticks. The bees will speedily ascend into it, and when they have done so, the hive may be put in the place of the old stock. If more convenient the removal may be deferred till early the next morning, but should be effected before sunrise, and precautions must be taken against any rain which may fall in the meantime. We should remove the transverse bars, which are only useful in supporting the combs when travelling. We believe there is no objection whatever to growing dahlias near an apiary.]

#### SWARMING VERSUS STORIFYING—ENLARGEMENT OF SUPERS.

A FEW observations have appeared lately relative to the subject which forms the heading to these remarks. Our friend "J. E. B.," with whom I have had the great pleasure of becoming personally acquainted within the last few days, at page 444 has expressed his belief that a larger harvest of honey will be obtained from hives that are permitted to swarm than from those which are worked on the non-swarming principle. I cannot agree with him in the conclusion at which he has arrived from what may be reckoned as experience gained from two exceptionally prolific honey years. In the majority of seasons he would obtain little or no honey by following his plan. If "J. E. B." had worked the same three hives without allowing them to swarm, or had succeeded in preventing their doing so, I think his supply of honey would have been nearly, if not quite, doubled, if

having swarmed, they afforded him so good a harvest as an average of 35 lbs. each. But this quantity cannot be considered as all gain, for he says that he had to feed liberally. It is frequently the case when large supers are taken from hives that have also thrown off swarms that little honey will be found stored in the stock hive. I have more than once in my early bee-keeping days had to regret the loss of a fine stock from this cause, it having succumbed to starvation before I had realised the fact that a super of honey, and plenty within the stock, did not always go together.

I quite agree with much that is said on this subject by "A RENFREWSHIRE BEE-KEEPER." I always look upon the issue of a swarm from any of my depriving-hives as a great misfortune, and as a bar to the completion of any super which may have been commenced. I do not, however, often return the swarms, never, I may say, except with frame hives, where the combs may be readily examined and the royal cells removed. Without such facilities, to return swarms to storified stocks may involve a great deal of trouble, ending occasionally in the loss of the hive or swarm altogether.

"J. E. B." quotes Dzierzon as an authority in support of his opinion that a larger supply of honey will be afforded by a hive permitted to swarm than from a non-divided stock. Where there is a little limit to the number of hives that can be kept by one person I have no doubt that a larger profit can be obtained by allowing the bees to swarm extensively; but any bee-master who has reached the limit to which he can retain his apiary will do well to work at least half of his hives on the non-swarming principle. I have no hesitation in asserting that if any one can keep only a limited number, say of ten hives, he would be able to obtain much larger supplies of honey by preventing swarming from the majority of them. One or two swarms might be permitted for the purpose of keeping up the stock. These, and what would be likely to come without permission, would be sufficient for supplying deficiencies and securing the desired number of strong and well-furnished colonies.

In respect to affording additional room to supers I cannot quite agree with our friend "A RENFREWSHIRE BEE-KEEPER." The whole system of my management of late years has consisted of the very plan he reprobates as bad practice. So soon as the first super is nearly filled with combs a shallow eke is slipped in between the super and the stock, followed by another, if needed. It is in this way that all my large supers have been obtained. Very rarely have I succeeded in getting a super filled which was placed above one already nearly completed. I can only recall one such case. Perhaps I have not tried very often, as I considered the prospects of success about on a par with expecting a good yield of honey in a box worked as a nadir. I consider slipping in an eke which has neither top nor bottom to be very different from raising the first super on a complete box with small apertures for communication. If this latter plan is followed the apiarian certainly runs a risk of finding the contents of the first super to be more or less removed. I have, however, taken off good boxes of honey under such circumstances, but do not recommend this mode of enlargement.

The bee-master must be guided in his judgment as to whether his super need enlargement or not by the time of the season and the appearance of the honey harvest. It is certainly preferable to have a moderate-sized super well and completely filled to a large one indifferently so. It is frequently advisable when a depriving-hive becomes very crowded with bees to follow "A RENFREWSHIRE BEE-KEEPER'S" advice, and raise stock hive and super on a nadir. The super will usually be completely filled, and if the bees work in the nadir, which is doubtful, it can be removed at the close of the summer, and the combs made available the following year. I have more often than not found that a nadir supplied to a crowded hive, with a large super partially filled, is not at all used by the bees for comb-building. The bees cluster thickly from the top, and the great pressure of numbers in the super being removed, work in it will be proceeded with more rapidity. I fully endorse the sentiments of "A RENFREWSHIRE BEE-KEEPER," that all correspondents should be free to express their opinions, and even criticise the plans and proceedings of any of the

brotherhood. I know it will be done by him, at all events, in a good and proper spirit. Although I have somewhat condemned his practice of placing an empty super over one that is being filled, yet he seems to have found it to answer. On the other hand, he objects to the mode of practice which I have followed with so much success—that of raising partially filled supers on ekes placed between them and the stock. This is a fair subject for future experiment, and I hope to be able to try his plan as well as my own. An "AMATEUR," who details his experience at page 277, seems to have been very successful, and to have weighty reasons for upholding his friend's system. It is possible that there is, after all, no very great difference in the results likely to be obtained from following either of the two modes of management.—S. BEVAN FOX, *Exeter*.

DEATH OF A QUEEN.

On the 4th of April I put some pieces of honeycomb before my hives for the bees to clean. In the afternoon I discovered feeding upon the comb a queen bee, but in a very weak condition, with one wing torn. I brought her into the house and succeeded in reviving her. Having six stocks I was quite at a loss as to which of them the queen belonged to, but as evening was approaching I went out in perplexity to inspect the hives. My doubts were speedily at an end, for there was extreme noise and excitement in a strong stock in a bar-frame hive. I brought out the queen immediately and put her at the entrance of the hive, into which she crawled slowly, being still weak. In half an hour the hive was perfectly quiet. I made sure the stock would now be all right as it was very strong in bees, but the queen was about four years old. On the 26th of April Mr. Carr, of Newton Heath, being on a visit to us, inspected all my stocks, and found in this one drone brood in all stages of development in worker cells, but no queen, and it appeared very evident that these eggs were laid by worker bees. This being the case Mr. Carr joined to the stock some bees and their queen, the remains of a colony the majority of which had died of dysentery in the spring. Two combs containing brood were cut out and put into the hive after the bees had been successfully joined. The next day we found a small dead queen thrown out, which had the appearance of having been defunct some time, leading one to suppose that the bees would not part with the body of their beloved queen till they had received a fertile successor. We examined the hive afterwards and saw the beautiful queen quite at home, running about on the combs, and I expect to have a large super filled with honey from this stock during the summer. Your readers will perceive how necessary it is to have every stock examined in the spring. In this case if it had not been done the bees would gradually have died away, and probably by July there would not have been one left, although the hive in April contained plenty of honey, and was very strong in bees.—J. M. W.

[The old queen was doubtless expelled from the hive; and as you state her age at about four years there is a fair probability of her having become unfitted for her maternal duties, although we have known the same thing happen to queens that were by no means superannuated. The occurrence of fertile workers is so rare that the hypothesis of their existence may generally be altogether set aside. In this case there certainly were none, but a young queen was reared after the expulsion of her predecessor, and which, remaining a virgin owing to the non-existence of drones so early in the season, must, perforce, have become a drone-breeder. She was doubtless imprisoned and killed on the advent of the fertile queen, her body presenting the usual dried and shrivelled appearance consequent upon the treatment she had been subjected to during her incarceration. "All's well that ends well," and in your case there is fortunately nothing to be regretted; but you made a great mistake and ran a very great risk of losing the whole by not removing the drone-breeder, of whose existence the presence of drone brood afforded *prima facie* evidence, and who should have been sought for until found. Very recently our esteemed correspondent "J. E. B.," under exactly similar circumstances, having, in deference to a caution which we gave him on this very point, exhausted his patience in

the unavailing endeavour to discover a drone-breeder, added to a drone-breeding stock the fertile queen and workers of a weak colony, and had the mortification of finding the new sovereign cast out dead the next morning.]

HONEY FLAVOURED BY ONIONS.

"A MAN OF KENT" may safely conclude that the smell emanating from his hives is produced by the bees resorting to the wild garlic. The reason why I conclude it to be so is this: In accompanying my honey for disposal to Messrs. Fortnum and Mason's in 1859 I was struck by the appearance of a good-looking lot of honeycomb, but its beauty was all that it had to boast of, for it smelt and tasted most villainously of onions. The foreman of the honey department informed me that it was sent to them from Essex, and that it had been produced in the neighbourhood of a field of onions that were grown for seed. It was contemplated to run it off, throw it away, and melt down the combs, as in any other shape it was perfectly unsaleable.—UPWARDS AND ONWARDS.

OUR LETTER BOX.

COLOURED PLATES OF FOWLS—BROWN REDS NOT COMING TRUE (*Partlet*).—The best drawings of fowls are those in the "Poultry Book." They are by Harrison Weir, and coloured. They are in his best style, and well worth framing. We know the coloured etchings you speak of, and recollect the time when they came up. They are all by H. Atken, a printseller, who lived at the corner of Vere Street, close to the Church; he was famous for them. He has been gone for many years. The last time we saw any of them was a short time since; they were in a shop window in Holywell Street. An advertisement would get them at once. Brown Reds do not always throw pure, as almost all the strains are mixed with Black Reds, which are used for colour.

COCHIN HEN WITH ENLARGED CROP (*Eboracum*).—Your hen has been suffering from much internal fever, and probably is so still. This induces her to drink continually, and has caused distension and displacement of the crop. It is sometimes incurable. The treatment is to shut up the bird, to purge with castor oil, and to give water sparingly. If it be mixed with vinegar so much the better. The water may be given three or four times per day, but not allowed to remain by her.

DORKING COCK DISAGREERING WITH A CRÈVE CŒUR HEN (*Beta*).—It is unquestionable that fowls are subject to likes and dislikes, and no doubt in this instance the cock has an antipathy to the hen in question. Such being the case we advise you to withdraw her. A daily beating is antagonistic to condition, and may account for her not laying. Put her with the Cochin cock.

COCK'S COMB FROSTED (*W. R. P.*).—Rub the comb with strong camphor ointment frequently.

INDIAN CORN AS FOOD FOR POULTRY (*Chanticleer*).—Indian corn is a good occasional food for adult poultry. It is not good for chickens—in fact, not good enough. We do not consider Pigeons injurious to a garden.

DUCKS (*Constant Reader*).—They will not injure the Perch nor any other kind of fish in a pond.

DIARRHŒA IN PIGEONS—KEEPING THEIR EGGS (*W. H. W.*).—Feed your Pigeons on small old beans. Give as a corrective three or four pieces of old mortar or chalk, about the size of peas, every day till the looseness is cured. Pigeons' eggs are best set as soon after being laid as convenient. It is reported that they will keep good for hatching about a fortnight, but I have never tried them.—B. P. B.

PIGEON PAIRS (*Miss King*).—It is one of the popular errors to suppose that the two Pigeons in a nest are always cock and hen—they are quite as often two of one sex. There is nothing singular in Doves having two hens in a nest, but is it certain that the Doves are Ring Doves (*Columba palumbus torquata*), which is our largest native Dove or Wood Pigeon, of a greyish blue color, with a white ring round its neck? If they are an account of their breeding in confinement would be interesting. I suspect, however, that the Doves are Collared Turtles (*Columba risoria*), the laughing Dove, or common cage Dove, of a light fawn colour, with a black ring round the neck, as these are sometimes improperly called Ring Doves.—B. P. B.

GERMAN PASTE FOR BIRDS (*R. F.*).—Take 1 lb. of wheat flour or of pease-meal, 2 ozs. of fresh butter, 4 ozs. of brown sugar, three eggs boiled hard and chopped very small; put the flour or meal, with the butter, chopped eggs, and sugar, into a wide saucepan over a slow fire, and keep stirring it to prevent its burning. When it gets dry continue stirring it until it become crumbly. When crumbly put a pint of cracked hempseed into the mixture and mix well together. If burnt it is injurious to the birds. It will be good for months if kept in a dry cool place.

LONDON MARKETS.—MAY 15.

POULTRY.

We have no difference to quote since last week. The supply is very small and the demand bad.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 67.1°, and its night temperature 44.3°. The greatest heat was 91° on the 28th, 1847; and the lowest cold, 26°, on the 23rd and 25th, 1863. The greatest fall of rain was 0.97 inch.

ROSES IN GROUPS.

HERE are few of the readers of THE JOURNAL OF HORTICULTURE who do not feel deeply indebted to the Rev. W. F. Radclyffe for his most excellent and practical hints on the cultivation of the Rose, his favourite flower, given from time to time in these pages. Nor can we feel less sensible of the honour done the "queen of flowers" by "D., Deal," Mr. W. D. Prior, and other amateur horticulturists in their articles. I cannot but observe that these gentlemen pay especial regard to their favourite flower, and having their energies rivetted, as it were, on one or two particular subjects are enabled to be more successful and acquire a greater insight into these than we gardeners are able to

do from the great variety of subjects daily demanding our attention. No wonder then that they are so well qualified to give advice, and that their papers are read with so much interest as being the experience of those who well understand the subject, and are, besides, enthusiastic in their love and treatment of the Rose. I fully believe that our distinguished Rosarian of Tarrant Rushton is possessed of a florist's eye, and views the Rose through no other, whilst there cannot be a doubt of "D., Deal," not seeing any merit in those Roses that will not go through the ordeal of an examination by florists. The circular form is all-powerful with a florist. A Rose must not only be of good habit, possess fine healthy foliage, and be profuse and continuous in its blooming, but it must have a certain shape of flower, much substance of petal, and open well, or it will not suit a florist. His standard is that of a good flower; he does not mind so long as he can obtain a few good blooms from a plant so that he may exhibit them in a stand on a certain day, and by the merits of the flower alone the judges award the prizes, little being known of the habit and hardness of the plant. Gardeners, on the other hand, require the flower to be not only of good shape or form, but profuse-blooming and lasting, enduring rain and sun, and opening well in all weathers; the plant hardy and vigorous, but not rampant. Whatever its habit it must bloom profusely, have fine, bright, bold, and healthy foliage, and be of good constitution generally. As to colour, we want this bright and decided, and not the colours that run with rain and fade with sun, and we could do with some good whites, which are scarce, and more of the true rose colour, but not one more of the crimson scarlets, unless decided improvements on the old ones. These are the Roses wanted for general purposes—good hardy Roses that are effective when in

bloom, or out of bloom through their foliage, fine for cutting, and also of fine form, such as Mr. Radclyffe recommends to be obtained by the hundred. Those that are inconstant and only open in certain seasons, and give but few flowers and fewer of them of good shape, are not suitable for general cultivation.

Besides these we want good Roses of dwarf, yet free, compact habit for groups or beds, the more free and continuous-blooming the better. A slight degree of imperfection in the flower is more tolerable than fine form with scarcity of bloom. A combination of hardiness, dwarf habit, profuse foliage and bloom, and a continuance of them is what is much wanted for groups. Good continuous-blooming Roses for groups are what we may long and wait for; but it would tend to hasten the attainment of the object in view if those amateur rosarians who grow new Roses for trial would record their experience of the kinds that, from their habit and profuse blooming, are adapted for beds, and give us their notes of the old which they have tried and not found wanting. Groups of Roses are highly pleasing when in bloom, and more encomiums are passed on them and more time is spent in looking at them than at all the rest of the flower garden. Everybody likes Roses, but their charms cannot be fully appreciated unless the blooms are seen in quantity. A score of varieties is not half so effective dotted here and there as when grouped in one spot with room for them individually; and a dozen, again, will be much more effective when planted in a group of one colour or variety than a hundred scattered here and there.

Dwarfs are the only description of Rose suitable for grouping, and they are best on their own roots. The next best are those on the Manetti stock, grafted or budded so low as to have both the stock and scion or bud covered with soil, so that they may derive nourishment from their own roots as well as from those of the stock. On their own roots they do better on dry, sandy, and gravelly soils than when on any stock with which I am acquainted; whilst those on the Manetti seem as if they do not care what kind of soil they grow in. The Manetti, though the best of Rose-stocks, and very desirable for grafting or budding Roses on in cold wet localities and strong soils, where it is not troublesome on account of its throwing up suckers, is rather troublesome in this respect in light soils, and in such these Roses do much better on their own roots. The Manetti after the first or second year does not cause trouble on the score of suckers, even in light soils, if pains be taken to remove the eyes when the cuttings are made, and to take these out afterwards quite close to the stem with a sharp knife. From carelessness or neglect in doing this effectually the Manetti stock sometimes sends up suckers, but it is never half so bad in this respect as the Dog Rose, which is of no value for light soils, its strength being expended in suckers, and, besides, Roses on it are short-lived. On cold, wet, heavy soil the Dog Rose is more at home, but even there it will throw up suckers, and these are extremely difficult to get rid of when the

Roses are planted closely or pegged down. There is no Rose suitable for our climate and for grouping that is not better on its own roots, and such alone are to be recommended, subject to conditions of soil and situation.

The ground intended to be planted with Roses should be well drained, dug deeply, and have a liberal application of well-rotted manure worked in. If the soil is light, the addition of strong loam from a pasture will be of service, and where it is little else than sand or gravel take the old soil out to the depth of 18 inches or 2 feet, and replace with strong loam—the top spit of a pasture, mixed with one-fourth of manure. If, on the contrary, the soil is very stiff, sharp sand or even road sand mixed with it will be of service. The bed should be formed rather high to allow for settling, and be raised in the centre, and if prepared in the autumn and forked over occasionally during the winter in dry weather, it would be in better condition for planting. May is a good time to plant out of pots in groups; March is better when the plants are taken from the open ground or are not in pots. Two feet apart is a sufficient distance to plant them, the first row being 18 inches from the edge of the bed if they are to be pegged down, if not pegged down they may be planted even nearer the edge, especially the smaller kinds of China Roses. When strong plants are to be planted, the most suitable times are November and December for summer Roses, and February and March for these and autumnals; they may be a yard from plant to plant, and should not be less than 2 feet from the edge of the bed. In planting, the roots may be shortened a little, but only those which are long and straggling, and the holes ought to be made sufficiently large to contain them without cramping. Avoid deep planting; from 3 to 6 inches is a sufficient depth to cover the roots, using rich compost for that purpose. If turned out of pots loosen the ball and disentangle the roots.

After planting mulch the surface with 2 or 3 inches of short manure, if planted in spring, having previously watered well. The manure is to be pointed in prior to giving the bed a good watering during the first dry weather. Instead of giving water in small quantities and often, reserve all for a good drenching when necessary, and keep the surface of the bed open, for what will let out the moisture will assuredly admit air and the night dew. Syringe the foliage as often as we may, it can hardly be done often enough to keep down aphides. If these be allowed to remain undisturbed a viscid substance will be deposited on the leaves, ultimately turning to a black fungus, and then we may bid farewell to healthy Roses. Give them plenty of water, and keep the surface open, and they will thrive. Do not attempt to peg the shoots down the first year, but thin these out to three, half a dozen or so, according to their strength. They will make strong shoots the first year, and be suitable for pegging down in autumn or spring. If this is done in autumn the ground should be forked over, and the shoots laid down at their full length, excepting the unripe portion of the shoot which may be reduced—say a three-foot shoot to 2 feet, and others proportionately. Lay them regularly over the surface, removing the soil near the stem so that the bend may not be too abrupt, otherwise the shoot may break. When pegged down place 3 inches of short littery manure on them, covering the whole surface; this will act as a protection, and through this the shoots will come in spring, and give a carpet of bloom in due season. I have not tried any of the more choice kinds in this way, but have every reason to believe it would answer well for the more delicate Teas and Chinas, which are mostly cut down to the ground by frost. It was common to treat the Provence in this manner some years ago, and finer beds of China Roses I have not seen than the following:—Clara Sylvain in the centre of a bed, with Madame Bureau round, the two forming a group of white Roses; Fabvier, scarlet; Mrs. Bosanquet, blush, with Cels Multiflore, also blush, round it; a crimson bed of Cramoisie Supérieure; one of Prince Charles and Carmine Superbe; another of Madame Bréon and Augustine Horsent; and, finally, a bed composed of Etna, Virginie, and Archduke Charles—all Chinas, and every one blooming from June to October. They were pegged down towards the end of November or early in December, pretty freely pruned or cut back, and then covered over with from 1 to 2 inches of lightish short litter. The soil was light, and they did not suffer in the least from frost. China Roses are, perhaps, the

most chaste and beautiful of all Roses in groups; they are so neat in habit and so profuse in their blooming. They should be pegged down in summer if the growth is at all irregular, but rather loosely.

Another mode of pegging down Roses is to encourage the strong shoots that come from the base of the plant, and in the following spring to peg these down regularly over the surface, merely cutting off the ends of the shoots, the ground being previously forked over and a liberal dressing of manure given. The plants so treated send up strong shoots from the base, and these are thinned or disbudded to from four to six joints according to their strength. The old shoots, or those previously pegged down, are cut away in autumn, and the shoots of the current year are pegged down in their stead either in autumn or spring. A number of short stubby shoots arise from those pegged down, and on them flowers are produced abundantly, and the effect is very good. The majority of the Roses that require close pruning do well in this way, and it is a good old practice well worth reviving.

Roses, however, are fine in groups, whether pegged down or not, and in the latter case the flowers though less plentiful are finer. There is scarcely a Rose which is not in some way beautiful; but I now ask for information as to what kinds are the most suitable for groups on lawns. They must have good flowers, be profuse-blooming, have fine healthy foliage, and be of dwarf habit, and so hardy as to be proof against ordinary winter frosts. I also wish to know what are the best stocks, or whether they are better on their own roots? I may observe that Roses on the Dog Rose produce numerous suckers not from the stock, as in the case of the Manetti, but from the roots, and the latter run so far underground as to give much trouble in finding outwhence the suckers spring. In light soils so many suckers are produced by the Dog Rose, and the Roses worked on it are so short-lived, that in my opinion it is of no value for dwarf plants. Where the situation is cold and moist, and the soil strong, Roses for groups do best when budded or grafted low on the Manetti stock, so low, indeed, that the plant may be on its own roots as well as derive support from those of the stock continuously, or for a time at least. For light soils and dry situations I have nothing to advance against it, only it requires plentiful supplies of water, and liberal treatment. Lastly, Roses are infinitely better on their own roots where the soil is dry and light, if afforded abundance of water to keep them cool, and liberal dressings of manure. These are the conclusions at which I have arrived, from my own experience in places situated widely apart, and in different soils.

The treatment of Roses in groups does not differ from that recommended for those pegged down, as regards soil, watering, &c.; but they are planted 2 feet apart for the moderate, and 3 feet apart for the more vigorous growers, and are pruned so as to be always kept low, higher in the centre of the group, and lower at the sides, the shoots being stopped during summer so as to give as even a surface as circumstances will permit, and all decayed flowers broken off. The shoots, if strong, should be stopped at the eighth joint, and at the sixth if moderately strong, and this throughout the season. An inch of short and cool manure spread over the surface will be beneficial during the summer, and a loose frequently-stirred surface is better than a fine smooth one. It may seem inconsistent to mulch the surface, and frequently point it over, but the soil should be stirred early in June, and then mulched; all watering after this will wash some nourishment into the soil, and the mulching being forked in after the first and principal bloom, healthy growth and better autumn-flowering will be encouraged.

I have had the following in beds or groups, and though they were good in some respects, they had their failings, not being continuous blooming enough generally. Perhaps some of your Rose correspondents will give us the benefit of their experience.

CHINA ROSES.—Cramoisie Supérieure, crimson scarlet (makes a fine group); Fabvier, scarlet; Cels Multiflore, blush or pale flesh; Madame Bréon, rose; Clara Sylvain, Madame Bureau, and the old white, sometimes called Lady of the Lake, whites; Prince Charles, red or carmine; Archduke Charles, rose changing to crimson; Mrs. Bosanquet, flesh; Citoyen de Deux Mondes, crimson; Eugène Beau-

harnais, deep crimson; Marjolin, deep crimson; Elise Flory, rose; Eugène Hardy, and Infidélités de Lisette, rosy blush. For edgings or small masses by themselves, the Miniature China, or Fairy Roses, are pretty. La Desirée; La Gloire, crimson; Le Pompon, rose. These and all China Roses require a light, rich, well-drained soil, and protection in winter. A few inches of litter on the beds will protect them sufficiently in mild situations, adding a few spruce branches stuck thinly in the beds in December, removing them gradually in spring. They should be pruned quite close in April, and if nearly to the ground they will grow the more freely. The shoots may be pegged down in summer; the effect is charming. In some instances it would be better to take them up in November, lay them in a cold frame, or under a wall, protecting during severe weather, and plant in the beds again in March. Such treatment is necessary in cold localities.

**BOURBON.**—Emotion, French white; Baron Gonella, rose; Catherine Guillot, rose; Baronne de Noirmont, rose; Reveil, crimson; Madame Angelina, fawn shaded salmon (too tender); Victor Emmanuel, and Sir Joseph Paxton, purplish crimson; and Souvenir de la Malmaison, flesh colour. They are best worked on the Manetti in strong ground, but are good on their own roots, on light, well-drained soil. Liberal treatment and close pruning are necessary.

**TEA-SCENTED.**—Madame Bravy, and Madame Villermoz, white with rosy centres; Rubens, white shaded rose; Gloire de Dijon, fawn (fine when pegged down); David Pradel, rose; Bougère, light rose; Devoniensis, creamy white; Auguste Vacher, fawn; Sombreuil, lemon; Vicomtesse de Cazes, yellow; Le Pactole, lemon, yellow centre; and Abricoté, fawn. Treatment the same as for the China Roses.

**HYBRID PERPETUAL.**—Géant des Batailles, Lord Raglan, Maréchal Vaillant, Pœonia, Sénateur Vaisse, Le Lion des Combats, Duchess of Norfolk, Général Jacqueminot, Baronne Halez, Madame Charles Wood, Madame Laffay, and Charles Lefebvre, all crimson, scarlet, or crimson scarlets; Abd-el-Kader, Jean Baptiste Guillot, Duc de Cazes, Triomphe d'Angers, Princess Mathilde, and Murillo, shades of purple; Jules Margottin, Louise Odier, Madame Boll, Baronne Prevost, Louise Peyronny, Comtesse de Chabillant, Caroline de Sansal, Auguste Mié, Comte de Nanteuil, Madame Knorr, Madame Vidot, and Adelaide Fontaine, rose and pink shades; Impératrice Eugénie, Louise Damaizin, Louise Darzins, Madame Canrobert, and Virginale (too delicate), white shades. These Hybrid Perpetuals are fine groupers.

All the preceding are pretty nearly autumn bloomers, and some of them continuous from June to November.

**HYBRID PROVENCE.**—Blanchefleur, and Princess Clementine are white, and make charming beds in their season, when pegged down or otherwise.

**MOSS.**—Reine Blanche, white; Crimson or Damask, carmine; Common (not yet beaten), blush; Vandaël, violet purple; and Frederic Soulié.

**PROVENCE.**—Cabbage, deservedly a great favourite; Unique Panaché, white rosy stripes, and the old White or Unique.

**GALLICA OR FRENCH.**—Boula de Nanteuil, purplish violet, shaded slate; Shakespeare, crimson; Cillet Parfait, white, striped red; Ohl, crimson; and Perle des Panachés, white, striped pink.

**HYBRID CHINA.**—Beauty of Billiard, red. Trained on a wire over a bed its effect is good, and so is that of Madame Plantier, white.

**HYBRID BOURBON.**—Paul Ricaut and Charles Lawson, the one a crimson, and the other rose.

These summer Roses are unrivalled for gorgeous masses of bloom in their season, and do well pegged down. They are best worked on the Manetti, except the more common, which do better on their own roots.—G. ABBEY.

### MRS. CHITTY AND HER CHILDREN.

The time has now arrived when the subscription in behalf of the gardener's widow and her babes will be closed. With the closing there has come, naturally and properly, the time when it is meet and right to render public thanks to every one of Mrs. Chitty's kind and liberal benefactors, and also it is the proper period to state, for the satisfaction of all

those who have generously come forward to assist, what are Mrs. Chitty's plans and prospects.

The widow thanks, from her very heart, every one who has given; she gives equally warm thanks to the wealthy who have given so liberally of their wealth, and to the poorest who have given as much—viz., a little of their very little. From her good husband's good master, who headed the list with ten guineas, and the generous widower (mark the force of well-directed fellow-feeling), who gave three sovereigns, to "Little Willie Earley," with his sixpence, and the "Three Workmen in a Garden," with their fourpence each, she thanks all. How sufficiently can I express for Mrs. Chitty the heart-cheering she has had each week, from kind gifts, and sometimes from kind letters. She feels, with proper pride, that he who was her husband so bore himself in life as to be honoured when in his grave, and she accepts all that has been given as given in testimony to his worth. Those who read this will be glad to learn, that as yet not one farthing of the money has been touched. This shows plainly that as far as they possibly could, Mr. and Mrs. Chitty have been careful and provident.

Mr. Webley engaged at once a single gardener in her late husband's place, thus assisting her with a lodger, kindly also allowing her something a-week, while Mrs. Webley sends two of the children to school. Upon my suggestion (one which Mr. Webley approves), Mrs. Chitty will presently open a shop in the village in which she resides, she being well liked where she is well known. Her friends best able to give an opinion, believe she will get on nicely. Every one has been kind to her. Her excellent clergyman has the care of the money; her landlord has offered her a good house, suitable for lodgers, and having a good shop. "As soon as the baby can walk" (touching little domestic incident), if not before, the business will be entered into, and the shop will be opened. Your money, kind subscribers, will thus enable Mrs. Chitty to start in business; you have given the means wherewith the shop will be opened—but for your liberality, so suitable and efficient a bread-winner could not have been dreamed of. Thus the widow has found warm-hearted and liberal friends near, among those who knew her personally; and equally good friends afar off, who felt respect for her late husband, and sorrow for her lone condition.

Good, kind subscribers all of you, you have lifted a heavy load of care from off a sad heart, which if it cannot beat as happily as formerly, will yet be (owing to you) a peaceful, a thankful, and a contented heart. Little cheeks will grow plump owing to you; and as the comfortably-dressed children will walk to the house of God, their mother will think of your kindness and liberality, and be saved, we trust, all her life, from that poverty which depresses the mind, and is as little a friend to the soul as to the body.

Accept, then, this letter as if written by Mrs. Chitty. I thank you all for her. If the reward of our Master was to follow the giving of the cup of cold water, much more shall you find that your christian liberality, like mercy

"Is twice blessed, it blesseth him that gives,"

as well as her to whom is given.—WILTSHIRE RECTOR.

### THE FROST OF APRIL 30TH.

It would be interesting if some of your numerous readers would record in your pages the degrees of frost on the night of April 30th. I have heard that in Surrey and Kent it was severe enough to kill the young shoots of Oaks, Walnuts, Ash, &c., and to do much damage to the fruit of Plums, Cherries, and Pears.

Here, in Hertfordshire, the thermometer on the morning of May 1st registered 27°, or 5° of frost. The young shoots of Oak were not injured, Walnuts had the tips of their leaves blackened, but have quite recovered. The young shoots of Picea cephalonica also escaped, as has all the fruit of Cherries, Plums, and Pears.

At Chiswick they registered 9° of frost, this must have been most destructive.

Here we had not had any rain, so that the earth was quite parched. I have always found that when dry, young fruit and tender vegetation will bear 5° of frost without injury—not so in moist weather.

It will, I think, be interesting to some of your readers if

you will tell us when the meteorological day ends. I am induced to ask this from observing in your record of the minimum temperature, and also in that of Chiswick, that I am always a day before the records. For instance: the minimum temperature of 23°, which you give as happening on the 30th of April, did not take place till the morning of the 1st of May, accordingly I enter it as taking place on that day; but I find, as stated above, that in the Chiswick, and also in your "Meteorological Observations," it is entered as taking place on April 30th. Does the meteorological day last till the following morning?—T. R.

[The Chiswick meteorological day is reckoned from 8 A.M. to 8 A.M. again, and the highest and lowest temperatures which have occurred during the interval are registered to the day to which the first 8 A.M. belongs. Thus, the lowest temperature in the twenty-four hours between 8 A.M. on the 30th of April and 8 A.M. on the 1st of May was 23°, or 9° below freezing—that indication, therefore, is put down to the 30th of April. This is the practice of meteorologists generally.]

### CROSS-BREEDING STRAWBERRIES.

THE statement made at page 362, only referred to Strawberries grown out of doors, and my friend, Mr. Standish, gives it a wider scope than I intended, when he applies it to plants under glass, and subjected to an artificial mode of treatment. There is no analogy between the two modes of culture, and no progress (as far as the million are concerned) can be looked for from seeds obtained from forced plants. My basis of argument is, therefore, different from that of Mr. Standish.

As to a large number of Strawberry plants going blind when forced, experienced growers know that some varieties are better adapted for forcing than others, and the cause of their becoming blind is also pretty well known. I have practised successfully this branch of culture for thirty-five years, and for ten of these consecutively. After a series of experiments, I found that the runners of the preceding year allowed to establish themselves around the parent plant, are those which offer the best chance of success, if in the following September they are taken up with all their roots and leaves, and planted singly in pots 4 inches in diameter, and 5 inches deep, half an inch being left for drainage. It is unnecessary to state here what compost should be used; the Strawberry takes soonest in a good rich compost in which the fibrous roots can run. In potting care is taken to give these roots an oblique direction from east to west, following the course of the sun, and to pot the plants up to the neck in order that adventitious roots may be produced, as well as fibrils and spongioles. Plants with a large, compact, well-furnished crown are the best. After potting, the pots should be placed in a spot sheltered from the sun's rays and drying winds; but when the plants have taken fresh root they are exposed to the sun. Here the crown becomes firm and more solid, and it is from a well-established crown of this kind that perfect flowers and fine fruit must be expected. The footstalks of the flowers spring from the sides of the crown at the points where the runners are emitted, but the crown nourishes them by developing the leaves which draw towards the flowers and fruit the nourishment taken up by the spongioles. The crown must not be excited till the approach of the shortest day, or soon afterwards. This is the time at which the sap of all plants begins to become active, and their seeds to germinate, when placed in a moist artificial heat. If, notwithstanding these precautions the flowers prove abortive, their doing so must be attributed to too high a temperature, to want of sufficient air, or to too little water being given, from one or other of which causes the organs of fructification have been imperfectly formed.

Whilst writing these lines I have received a letter from a constant reader of THE JOURNAL OF HORTICULTURE, who, living in the country, has both the leisure and desire to experiment in raising varieties from seed, and he asks for further information on a point in one of my articles—namely, the choice of the seed of the Strawberry.

Though I positively have not the time to reply to this kind of correspondence, still as my views on the subject may be of some interest to others as well as himself, I willingly

accede to his request, hoping, however, that it will be the last time I may be called upon to write upon the Strawberry, being anxious to take up a subject of greater importance.

The seeds of the Strawberry, as any one knows who has eaten the fruit during half a century, are dotted over the surface of the fruit, or sunk beneath it in little pits. When a variety possesses desirable qualities, and the plants have been well grown, are vigorous, three or four years old, and have been in the same position for two years, we see arise in spring from the two sides of the plant and its subdivisions around the crown, two, three, or four foot-stalks each 3 or 4 inches long, and producing at the end of the pedicels from five to ten or more flowers. Which of these flowers is it best to retain in order to have perfect seeds? That which is in the midst of the corymb, and which has the thickest pedicel, allowing each plant to bear only two or three fruit. The whole of the sap being directed towards these, they ought to exhibit the full degree of perfection as regards form which the variety possesses, and the seeds ought to be large, and have a high degree of vitality, especially if the fruit has been allowed to ripen perfectly. In order that this may be the case, the fruit attached to its pedicel and the common footstalk, is laid along a flower-pot placed on its side.

When the fruit is gathered the upper part is taken off and thrown away, and the middle portion all round the fruit is alone preserved. The seeds are left in their receptacles to complete their ripening, and become solid. This portion of the fruit is kept in a paper bag, open at top, hung up in a place with a mean temperature of from 50° to 60° till the time of sowing. The most suitable period for doing this is in the course of January. The seed is sown in pots, or pans, of light sandy soil in the same way as other small seeds, and they are barely covered, bedewing them lightly and placing a glass over them. The pots are then placed in a pit or greenhouse, and as near as possible to the glass. When the radicle and plumule are perceived, some light soil is scattered over the surface, and when the seed-leaves have grown a little, the seedlings are pricked out singly in small pots, watered gently but freely, and placed close to the glass on a shelf in a greenhouse. By the end of March the young plants will have gained some degree of strength, and if the weather is favourable they may be placed out of doors. In April or May they may be planted out 18 inches apart, and to prevent mistakes the runners are cut off as they appear. Not unfrequently young fruit are perceived on these seedlings in the following July, but it is only in the second year that their merits can be judged of with any degree of certainty. To every plant remarkable for its growth, fine fruit, or other qualities, a piece of stick is placed as a distinctive mark. In September these plants are numbered regularly, taken up along with their runners, and planted 3½ feet apart in a bed by themselves. There the task of studying them and noting their qualities should be carried on, and it is not completed up to a certain point until after the second year of bearing—that is, till four and a half years after sowing.

The remaining seedlings, those not marked and planted by themselves, are replanted after throwing away all those which from their growth and bearing are not satisfactory to the raiser. It is rare to find among such plants a variety of particular merit, for a really good seedling usually exhibits its characteristics when eighteen months old, and these are pretty generally maintained even in yearling plants. This observation likewise applies pretty generally to all other seedling fruit trees.—J. DE JONGHE, Brussels.

MR. DE JONGHE says that when he hears of any one having artificially fertilised a flower of any hermaphrodite Strawberry he doubts the truth of the statement. I am perfectly confident that I made seven or eight distinct crosses last summer. The plan I adopted was this: Early in the spring I potted plants of the varieties intended for the seed-bearers. These I placed in a glass structure, from which insects were carefully excluded. As soon as it was possible to do so I turned back the corolla of every flower (I only left five on each plant), and with a sharp-pointed pair of scissors cut away and threw out of the house the stamens and anthers. So soon as the flower was perfectly expanded, and about noon, I carried the pot to the bed con-

taining the varieties the pollen of which I wished to use, and carefully dusted this over the flower of the plant from which the anthers had been removed. I repeated this operation the next day.

When the fruit became ripe I peeled the seeds thinly off, and spread them with a blunt knife on the surface of pans prepared for the purpose, and then after sifting a little light soil over the seed plunged the pans in coal ashes. Some of the seeds vegetated at once, but the severe winter killed a good many of the plants. However, about the beginning of March numbers of little plants appeared in all the pans, save one, which contained seed from May Queen fertilised with British Queen. I cannot satisfactorily account for my non-success with this cross, since I raised a number of plants two years ago from the same parents, and, indeed, I have about a dozen of the breed on further trial, though I fear there is not one really good amongst them.

Several bloom as early as May Queen, but though superior in size and flavour they did not last year ripen so soon. I suspect, as Mr. Radclyffe observes, that not one in a thousand seedlings is better than varieties already out.—P.

### SULPHUR FUMIGATION—NECTARINES SETTING SPARINGLY.

MR. RIVERS, in his "Orchard-House," speaks of a "13-inch pot, half filled with unslaked lime, to be saturated with four or five gallons of water, and then sprinkled with 1 oz. of sulphur," as a remedy for red spider in an orchard-house. I have tried this plan, and the result is—the lime is so saturated that the pot is full of a liquid pudding, destitute of heat, and the sulphur is not in the least affected. Will you kindly tell me whether this scheme is a good and safe one? and whether I am right in supposing the proper way to be to use so much water as will bring the lime to a hot powder, and then sprinkle the sulphur on it? I have no red spider, but am anxious to be prepared.

Will you also tell me whether Nectarines are considered more shy in setting their fruit in orchard-houses than Peaches? Mine were loaded with bloom, but have set sparingly, while Peaches have to be freely thinned. The calyx of the Nectarine blossom seems to dry up, and remain tightly enclosing the young fruit, which it fairly strangles, and the fruit drops. This has been the case with thousands of mine. The trees are in the highest health and finest foliage, and are treated just like the Peaches, among which they stand. You will observe, from my note, that the Nectarines do apparently set, but when the calyx should crack, and shell off, it remains on, which looks like the young set fruit.—C. P.

[You have used too much water for your lime. The sulphur should be applied before the heat goes off, or it will be of no use; and there is such a difference in the strength of lime, that we are always afraid to recommend the plan, except to those well initiated in such matters. One thing should be kept in mind—never to expose the sulphur to a greater heat than 170°, if you wish to be safe. As you are not troubled with red spider, we would recommend a free use of the syringe, and, if you have walls or wood, daubing them with sulphur where the sun will shine freely on them.]

Your case of Nectarines refusing to swell, and throw off the calyx, whilst Peaches next to them do so freely, is just one of those cases which could not be explained without knowing all the particulars of their culture, &c., since last August. Very probably the very luxuriance of the trees may have something to do with it, as the wood might not be sufficiently ripened. Deficiency of moisture, and too much at a time, will also cause the evil, but not to Nectarines more than Peaches. We never received the letter you allude to.]

### REMOVING FLOWER-STEMS FROM TULIPS.

IN your No. 216, under the above heading, you say, "We do not expect any particular good will arise from cutting off the flower-stalk unless it shows symptoms of seeding, when it had better be taken off." Allow me to make the

following remarks:—If the Tulips are the common selfs now used for bedding purposes, it may be of little consequence what is done to them; but if they are the beautiful varieties of fancy Tulips, formerly in such repute, then the cutting down would be, I consider, injurious to the bulbs; by leaving the stalk until it withers, the bulb discharges its superabundant sap, but if cut down the sap is prevented from being discharged, and the consequence is that the next year the delicate varieties blow with too much colour, or the colours run and improperly blend together, and the true character of the flower is spoilt. When the bulb shows symptoms of seeding, cut off the seed-vessel, but in all cases leave the stalk to ripen and wither.—W. H.

### ROYAL HORTICULTURAL SOCIETY.

MAY 16TH.

FLORAL COMMITTEE.—Another very successful meeting was held on this day. It is most encouraging to see how well these alternate Tuesday meetings are supported and appreciated; and it must be very evident to all interested in the Society's welfare that a new, vigorous, and healthy spirit has come over the Fellows, who now so numerously attend these meetings. Putting aside the interest taken in the new plants, flowers, and fruits, which are specially brought before the Committees on these days, the valuable and interesting collections of plants, many of which have passed their ordeal before the Committee, and received the award of their respective merits, which are now exhibited both for comparison and in confirmation of the judgment of the Committee, give an additional and very beneficial interest to these meetings. The special thanks of the Society are due to both the amateurs and nurserymen, who so kindly contribute them.

The awards on this occasion were as follows:—Mr. Veitch received first-class certificates for the following new plants: *Odontoglossum cordatum*, a beautiful Orchid, suited to a cool temperature; *Anæctochilus Domini*; *Goodyera Domini*; *Bertolonia guttata*, a very beautiful-foliaged plant, with deep rose-coloured spots on its dark green leaves, a pleasing contrast with *B. margaritacea*, with its pearl-like spots; *Pleroma* species, a very beautiful kind, with large bright purplish flowers; *Bertolonia pubescens*, with bright green leaves, each deeply marked with a broad black band down the centre; *Retinospora obtusa nana aurea*; and *Philodendron* species. Special certificates were awarded to Mr. Veitch for *Rhododendron Veitchii*, a very handsome plant, with large pure white flowers, exquisitely scented; for his collection of Orchids; also for his very magnificent collection of plants, in which were several new Azaleas and others.

Mr. Wills, Oulton Park, exhibited two seedling Zonate Pelargoniums not in condition; Mr. Southby, Clapham, two seedling Zonate Pelargoniums, Black Prince and Golden Queen; the latter it was requested should be seen again later in the season. Mr. Salter, Hammersmith, received a first-class certificate for *Polygonum filiforme variegatum*, a hardy plant; also for *Sedum Telephium variegatum*, a very beautiful plant. Mr. Smyth, gardener to Lord Sondes, had a first-class certificate for a seedling *Boronia* (*Drummondii*?) *alba Smythii*. Mr. Bull received a first-class for *Calonyction sanguineum*, a stove climber, with dark reddish brown leaves, a useful and very quick-growing plant; and *Ficus Porteana*, with very long leaves, an extremely handsome-foliaged plant. Among Mr. Bull's collection were *Dioscorea anæctochilus*, the plants too small to judge of its merits, which were generally thought promising; *Mimulus Lucifer*, a hybrid from *M. cupreus*; *Acer polymorphum foliis dissectis variegatis*; *Azalea Queen of Beauties*, very pretty and pleasing in colour; *Lychnis senno variegata* from Japan; the plant not having sufficient flowers upon it, made it doubtful whether the variegation would prove constant and permanent. He also sent four specimens of *Amorphophallus*, one of the curious but not uninteresting genera of Arads, remarkable for producing its oddly-formed spadix and one leaf, which is divided into three branches, with more or less divided segments; and a very inferior variety of *Polygonum filiforme variegatum*. Messrs. Backhouse, York, received first-class certificates for *Myosotis rupicola*,

one of the most beautiful of the Scorpion Grasses, of extremely dwarf habit, found on the Teesdale mountains. A letter from Messrs. Backhouse informs us that the identical plant exhibited was growing two days previously on a mountain covered with snow. *Androsace chamajasma* and *Andromeda fastigiata* likewise came from the same exhibitors.

Mr. Turner exhibited an extensive and valuable collection of Tulips, which were well arranged and carefully named. A special certificate was awarded them; also to a fine collection of Azaleas. W. W. Saunders, Esq., exhibited an interesting collection of Arads, containing specimens of *Amorphophallus*, &c. Mr. Thompson, Ipswich, had a first-class certificate for *Aquilegia coerulea*, a very pretty Columbine; and Messrs. Henderson, Wellington Road, received special certificates for a fine collection of half-hardy bedding-out plants, *Centaureas*, &c.; also for a general collection, including stove and greenhouse plants. J. Bateman, Esq., received a special certificate for a beautiful and well-grown specimen of a Bornean Orchid, *Cœlogyne pandurata*; and a similar award was made to Mr. Smith, gardener to H. S. Norris, Esq., for *Renanthera coccinea*, an Orchid not often seen in flower. Mr. Culley, gardener to W. W. Buller, Esq., received a special certificate for three specimens of *Cypripediums*, among them a very fine specimen of *C. caudatum*. A special certificate was awarded to J. Day, Esq., for his superb specimen of *Dendrobium densiflorum*, awarded at the previous meeting but omitted to be signed.

FRUIT COMMITTEE.—J. B. Haig, Esq., in the chair. Mr. Earley, of Digswell, sent a collection of six dishes of dessert Apples in competition for a prize that was offered for this class, and Mr. Earley being the only exhibitor, and his collection being in admirable condition, he was awarded a first prize. Mr. De Jonghe, of Brussels, sent specimens of *Bezi Mai Pear*, some of which were soft, they could not be called melting, and the Committee was of opinion that it is not equal to *Bergamotte Esperen*, which is now in season. He also sent a variety called *Basiner*, a crisp-fleshed Pear, having some relation to *Beurré de Rance* in that respect; but it was not considered a desideratum. Mr. Ingram, gardener to Her Majesty at Frogmore, sent a number of small Pears, the interior of which was quite a nest of small grubs, the larvæ of some insect, which, Mr. Ingram states, is creating great havoc among the Pear crops in the Royal garden.

At the scientific meeting the Duke of Buccleuch, the President of the Society, took the chair. This, like the preceding meetings, was well attended, and, as will be seen by the above reports, the collection of plants, &c., exhibited was very interesting.

The Rev. Mr. Berkeley, in proceeding to point out the most remarkable objects, took occasion to advert to a variegated *Sedum* or *Sempervivum* which had been exhibited at a previous meeting, and which, not being in flower, had puzzled everybody to determine what it was. He had now found that it was a plant once common in cottage windows—the *Sedum azoides*, of De Candolle's "Plantas Grasses." It was said to be originally introduced into this country from Madeira; but Mr. Lowe, who had studied the flora of that island for twenty years, had not found it there. With reference to the *Nardoo* exhibited on the 18th ult., it was stated that there were several species. *Marsilea salvatrix*, on the spores of which the expedition of Burke and Wills had subsisted, was the least common; and he found that the sporangia of the plant sent by Lady Dorothy Nevill differed materially from those of *salvatrix*, and belonged to *M. Drummondii*. Passing on to the Orchids exhibited, Mr. Berkeley briefly noticed *Odontoglossum cordatum*, *Cœlogyne pandurata*, *Dendrobium Wardianum*, *Cypripedium caudatum*, and *Orchis fusca* from the South of Europe, differing, he said, slightly from our own form of the same species. Orchids, as their cultivators were well aware, were liable to be destroyed by fungi, and it was very desirable that these should be investigated, in order that their attacks might be prevented or a remedy found. As an example of the damage which they do he instanced a leaf shown him by Mr. Pilcher at the last meeting, and which was almost entirely destroyed by a parasitic fungus consisting of radiating threads, forming at different points little bundles. These, on being magnified, he found to be a plexus of threads, which, though no doubt

reproductive, were not the real fructification. All growers of plants were aware how destructive fungi are to the roots of plants; and he cited two *Deodars* planted near Sir W. Hooker's house at Kew, one of which grew well, and the other would not grow at all, and on the latter being dug up it was found that it had been planted where an old Cherry tree had been cut down; and in his own garden several plants had died suddenly from fungi attacking the roots. Now, it was generally considered that one fruit tree would not grow where another had been, and this was attributed to the exhaustion of the soil by its former occupant; but the true explanation of the cause he believed to be the fungi existing on the old roots attacking those of the newly-planted tree. Among the variegated plants exhibited particularly worthy of notice were a beautiful variety of *Arundo donax*, and *Ilex Fortuni*, which, he had been informed by Mr. Fortune, is very beautiful in its own country where it is much used for hedges. In speaking of a *Podocarpus* exhibited at the last meeting, he had mentioned that the white shoots might give off green ones, but that plants could not be propagated from those which were entirely white. There was, however, a remarkable exception to this rule, which he gave on the authority of M. Barral, of the *Jardin des Plantes*, at Paris, who stated that the variegated *Ground Ivy* though perfectly white struck root, but the plant ultimately lost its variegation altogether, becoming quite green. Some plants, however, produced parts perfectly colourless, as instances of which, two plants in the room, *Mussenda frondosa* and the beautiful *Clerodendron Thomsonæ* were adduced. Among plants remarkable for their beautiful foliage, were "*Dioscorea anætochilus*" (?) and *Bertolonia guttata*, the leaves of which were set with little jewels formed at the base of the hairs. Some hybrids raised by Mr. Dominy, and shown by Mr. Veitch, were remarkable as having been effected between what were considered two very distinct genera—namely, *Goodyera* and *Anætochilus*, and the habit was far more hardy than that of the *Anætochili* in general. With regard to *Rhododendrons*, a curious fact was stated by Mr. McNab—namely, that he obtained totally different varieties by fertilising with the shorter stamens instead of the longer. He (Mr. Berkeley) had mentioned on a previous occasion the poisonous properties of *Rhododendron cinnabarinum*, and by way of contrast he would now add, that in India the flowers of *R. arboreum* were boiled down and the juice made a good jelly. This, however, was not the only instance of parts of the flower being employed for such a purpose, for one of the best of jellies, the *Rozelle*, was made from the fleshy calyxes of *Hibiscus subdariffa*. Mr. Berkeley then commented on the Alpines exhibited by Messrs. Backhouse. Few things were more lovely than the *Myosotis*, which though it came from the Teesdale Mountains was also to be found on Ben Lawers. Another gem was *Andromeda fastigiata*, nearly related to, but not the same as, *Andromeda hypnoides*. Of *Retinospora obtusa aurea* Mr. Veitch stated in a letter that it was the finest variegated plant in Japan, not even surpassed by *Thuja aurea* itself.

Among other plants noticed were *Calonyction sanguineum*, a climbing plant with large bronzy leaves, several *Arums*, and *Ficus Porteana*, which though a stove plant, bears a good deal of exposure, from its leaves-being excessively coriaceous. A *Begonia* leaf from Mr. Earley, Digswell, producing a multitude of young plants from the petiole, was also exhibited as a curiosity.

The awards of the Floral Committee were then read by the Rev. J. Dix, and the objects submitted to the Fruit Committee commented on by Dr. Hogg; after which the Duke of Buccleuch, in proposing the usual votes of thanks, said that he believed these meetings were of very great service to the Society, and the public at large, for not only were the things seen, but their advantages and peculiarities were pointed out, and, as in the case of the fruit, the best varieties were made known. From the number present the scientific meetings must be of very great interest, and the Saturday meetings had been very acceptable to numbers of persons who could not attend on Tuesday. In conclusion, he congratulated the Society on its improved financial condition.

A ballot for plants then took place. Fifteen new members were elected.

## CRYSTAL PALACE SHOW.—MAY 20TH.

THIS was the first of the great Shows, and never, probably, during the time that flower shows have been held in the Crystal Palace has so fine an array of the best specimens of English horticultural skill been presented at this or, indeed, any other season. The day was warm, the sky cloudless, and the sun bright, all of which are conducive to a large attendance of visitors; and whether it was from the amplitude of the ladies' dresses, the immense number of the visitors, or the length of time which they lingered around the tables, we never remember any exhibition so crowded as this, and in the afternoon to take notes of the objects shown was, in some cases, an impossibility, and in all little more than a passing glance could be obtained. The brightness of the day, however much it contributed to the financial success of the Show, was not without its inconvenience, for, notwithstanding that an awning was suspended over the tables, the plants in many instances, particularly the Azaleas, presented a very different appearance from what they did in the morning. The Roses, too, unfortunately had been placed where the sun had reached them, and though lovely even then, much of their freshness and beauty was gone. It should be borne in mind that the sun ought never to be allowed to touch a full blown Rose, for nothing can be more destructive to its beauty; yet the plants, though coming from shady houses with a temperature of 60° to a sunny one of 80° or more, from being in robust health, stood the change better than could have been expected.

**STOVE AND GREENHOUSE PLANTS.**—The specimens of these were large and generally excellent, though there was not much novelty among them. Being also shown in great numbers, they formed a very effective part of the display. Among them were many fine plants of Allamandas, Stephanotis floribunda, Pimeleas, Eriostemons, Aphelexes, Azaleas, Ericas Cavendishii and depressa, Epacrises, Ixoras coccinea and Griffithii, Chorozemas, &c. An Allamanda grandiflora from Mr. Peed was one of the most beautiful we have ever seen; it was so free-flowering, so graceful, and so pure in colour. *Rondeletia speciosa*, with its beautiful scarlet blooms, was also fine in Mr. Whitebread's collection; and a variety of *Azalea sinensis*, bearing a profusion of large yellow flowers, formed a conspicuous object in that of Mr. Rhodes. A charming plant of *Acrophyllum venosum* came from Messrs. Lee; and from Mr. Fraser, Lea Bridge, the beautiful *Clerodendron Thomsonae*, one of the best additions which have been made to exhibition plants of late years. The flowers for the most part were not fully expanded, but the multitudes of snow-white calyxes, with which the plant was studded, rendered it a remarkable object, especially when contrasted with flowers of brighter hues. *Medinilla magnifica*, with numerous long thyrses of flowers, and *Prostanthera lasianthos*, were also conspicuous in this collection. Good plants of *Rhynchospermum jasminoides* were shown by Mr. Williams, Mr. Baxendine, and others; *Mahonia incisa*, an old Cape plant, now seldom seen, by Mr. Smith, Norwood; the fine white *Rhododendron formosum*, and *Azalea Criterion*, a dense mass of bloom, by Mr. Carson; and the showy *Combretum purpureum* and *Diosma speciosa* by Mr. Kemp. In mixed collections of flowering and ornamental-foliaged plants, a beautiful plant of the elegant *Gleichenia semivestita* came, along with *Crotons*, variegated *Yuccas*, &c., from Mr. Williams; whilst in the collections of Messrs. Lee and Mr. Young *Cordyline indivisa*, *Cyathea Smithii*, and *Theophrastus* were well represented. An excellent plant of *Alocasia metallica*, the foliage in all its beauty, was also shown by Messrs. Lee.

Prizes were awarded as follows:—For sixteen, first, Mr. Peed, gardener to Mrs. Tredwell; second, Mr. Whitebread, gardener to H. Colyer, Esq., Dartford; third, Mr. Kaile, gardener to Earl Lovelace. For ten (nurserymen), first, Messrs. Lee; second, Mr. J. Fraser; third, Mr. Rhodes; fourth, Mr. Baxendine. For ten (amateurs), first, Mr. Carson, gardener to W. R. G. Farmer, Esq.; second, Mr. Page, gardener to W. Leaf, Esq.; third, Mr. Chilman, gardener to Mrs. Smith, Ashted House, Epsom. For six, first, Mr. Kemp, gardener to Earl Percy, Albury Park; second, Mr. C. Smith, gardener to A. Anderson, Esq. For twelve fine-foliaged and flowering plants, first, Mr. Williams, Holloway; second,

Messrs. Lee; third, Mr. Young, gardener to H. Stone, Esq., Leigh Park, Havant; fourth, Mr. Rhodes.

**HEATHS.**—There was a good bank of these, and on the whole the specimens were very good. Among them we noticed a fine plant of *Sindryana*, several fine plants of *ventricosa magnifica*, one of the best of its class, *odora rosea*, nice plants of *depressa* and *Devoniana*, and one or two beautiful examples of *Victoria*.

The prizes awarded were:—For ten, first, Mr. Rhodes. For eight, first, Mr. Peed; second, Mr. Page. For six, first, Mr. Wheeler; second, Mr. Chilman; third, Mr. C. Smith, Messrs. F. and A. Smith; extra, Mr. Kaile.

**AZALEAS** were placed at the four corners where the nave and transept intersect, and some truly magnificent specimens were exhibited. Mr. Turner took, as usual, the lead. Among his plants were *Gledstanesi*, exhibiting a more than usual disposition to sport, some of its flowers approaching the character of *Etoile de Gand*; *Arborea purpurea*, remarkable for its violet purple colour, so rare among Azaleas; *Juliana*, *Perryana*, *Gem*, *Barclayana* sporting to rose; *Coronata*, *Etoile de Gand*, many of its flowers wholly salmon-coloured; *Illustris nova*, the flowers nicely relieved by foliage; *Iveryana*, and *Criterion*. In other classes very good plants were shown by Messrs. Lane, Lee, and Williams; and Mr. Carson had excellent plants of *Iveryana*, *Murrayana*, *Double Red*, *Broughtoni*, *Triumphans*, *Duke of Devonshire*. Interesting collections of varieties, sent out since 1860, were exhibited by Mr. Turner and Messrs. Ivery. Prizes.—For eight (nurserymen), first and second, Mr. Turner; third, Mr. J. Fraser; fourth, Mr. Rhodes. For eight (amateurs), first, Mr. Carson; second, Mr. Whitebread. For six (nurserymen), first, Messrs. Lee; second, Messrs. Lane; third, Mr. Williams. For six (amateurs), first, Mr. Penny; second, Mr. Peed; third, Mr. C. Smith; fourth, Mr. Kaile. For new Azaleas, first and second, Mr. Turner; third and fourth, Messrs. Ivery.

**ORCHIDS** taken in the aggregate made a glorious display, though the individual specimens were not, as a rule, remarkable for their size. Their condition, however, indicated good and careful cultivation. Foremost came a fine collection of twenty from Mr. Bullen, grown in pots with open slits at the sides, extending nearly from the rim to the base of the pot. They had been well prepared for exhibition, and were set up with great care, and Mr. Bullen deserves credit for having brought them from Leicester in such good condition. They consisted of *Cypripedium barbatum superbum* with two score blooms; *Phalænopsis grandiflora*; *Camarotis purpurea*, a plant which requires some care in its cultivation; good *Vandas*; *Calanthe veratrifolia*, an old plant but still useful for exhibition; *Dendrobium macranthum giganteum* and *Lindleyanum*; a fine mass of *Cattleya Skinneri*, the rosy purple flowers of which are very effective; *Saccolabium curvifolium*, &c. In other collections, besides *Vandas*, *Cattleyas*, *Lælias*, *Ærides*, *Saccolabiums*, *Phalænopsis*, and *Dendrobiums* in plenty, we noticed the pretty white and yellow *Chysis bractescens*, the more recent *Chysis Limminghi*, *Odontoglossum Pescatorei*, the curious pale green and white *Brassia verrucosa*, several fine examples of *Dendrobium nobile*, *D. formosum*, with several of its large white and yellow flowers; *D. macrophyllum giganteum*, with a spike nearly 2 feet long; *Trichopilia crispa*, very fine; *Phajus Wallichii*; *Cyrtopodium punctatum*; *Cypripedium caudatum*, with two fine flowers, and the new *Phalænopsis Lüddemanni*, both from Mr. Wilson; *Cattleya Acklandiæ*, and *Sobralia macrantha*.

Prizes for twenty, first Mr. Bullen, gardener to A. Turner, Esq., Leicester; second, Mr. Baker, gardener to A. Basset, Esq.; third, Mr. Page. For ten, third, Messrs. Lee. For twelve, first, Mr. Penny, gardener to H. Gibbs, Esq., Regent's Park; second, Mr. Wilson, gardener to W. Marshall, Esq., Enfield; third, Mr. Young. For six, first, Mr. Bullen; second, Mr. Wiggins, gardener to W. Beck, Esq., Isleworth; third, Mr. Wilson and Mr. Chilman; fourth, Mr. Robson, gardener to G. Cooper, Esq.; Mr. Wheeler, gardener to J. Phillpot, Esq.

**PELARGONIUMS.**—Both show and fancy varieties in fine bloom were exhibited by Mr. Fraser, Mr. Turner, and Mr. Wiggins. Of the former we noticed *Etna*, *Sir Colin Campbell*, *Fairest of the Fair*, *Peacock*, *Leviathan*, *Sylph*, *Guillaume Severyns*, a peculiar lilac purple, *Lilacina*, pale lilac,

white eye, and dark top, Ariel, white with carmine spot, Desdemona, and Celeste, orange scarlet, white eye, and scarlet top, a very pretty variety. For twelve Mr. Fraser was first, Mr. Turner second, and in the amateur's class for ten Mr. Wiggins took the first position. In Fancies Mr. Fraser and Mr. Turner took the same relative positions. The former had Cloth of Silver, Arabella Goddard, Delicatum, Celestial, very fine, Roi des Fantaisies, and Queen of the Valley. In Mr. Turner's six the most noticeable were Ellen Beck, Celestial, Evening Star, and Roi des Fantaisies.

**ROSES.**—In the Nurserymen's Class for ten distinct varieties in 13-inch pots, Mr. W. Paul was first with remarkably fine plants of Souvenir d'Elise Vardon, Louise Odier, very fine, Madame Villermoz, Souvenir d'un Ami, Senateur Vaisse, Paul Ferras, Madame de St. Joseph, Catherine Guillot, and Comtesse de Barbantanne. In the collection of Messrs. Lane, who were second, we noticed Charles Lawson, Anna de Diesbach, large and fine, also Souvenir d'un Ami. In the Amateurs' Class for six, good plants were shown by Mr. Terry, gardener to A. G. Puller, Esq., Youngsbury, for which he received a first prize. The class for twelve Roses in eight-inch pots was also a good one. Here Mr. Turner was first, Messrs. Paul & Son and Messrs. Lane second. Mr. Turner's plants were remarkable for their fine condition, both as regards foliage and bloom, particularly Souvenir de la Malmaison, Senateur Vaisse, Madame Villermoz, and Charles Lawson. Good collections, as well as cut blooms, were also shown by Messrs. Paul & Son.

**MISCELLANEOUS.**—A very extensive and interesting collection of new plants came from Mr. Bull, comprising the new Japanese Aucubas, double Mimulus, his new variegated Verbena and Chrysanthemum, Zonate Pelargoniums, Petunias, and other objects, which have been noticed in recent Floral Committee reports. Mr. Robson, gardener to G. Cooper, Esq., sent the beautiful new Phalæopsis Lüdemanniana; and Messrs. Ivory, Dorking, four new varieties of hardy Ferns, all of which received first-class certificates—viz., Athyrium Filix-femina Fieldiæ compositum, ramo-cristatum, and two Scolopendriums, one of which, called variegatum, had a beautiful golden tinge in the fronds. Mr. Turner sent Liliun auratum, and a fine stand of Tulips; Messrs. Downie & Laird, and Mr. Shenton, Pansies; and W. Hoyle, Esq., Reading, a beautiful new Pelargonium, Charles Turner, which received a first-class certificate. It is a fine bright scarlet, with a dark top and white eye. From Mr. Turner came Pelargonium Marion, which also received a first-class certificate—rose, with a very dark top and a large white eye—a showy variety; also Elegans, rose and crimson lower petals, conspicuous white eye, and dark top. The pretty white-flowering Deutzia crenata flore pleno was shown by Mr. Shenton, Clematises by Mr. Townsend, Beaton's Geraniums by Mr. W. Paul, and a number of tastefully-filled plant cases by Messrs. Barr & Sugden.

#### FRUIT.

For so early in the season there was a tolerably good show of fruit as regards quantity, and the quality was fair.

In Pines Mr. Mills, gardener to Lord Carrington, High Wycombe, was first with a good Providence; Mr. Page second with a Cayenne weighing 6 lbs., and third with a 4-lb. Queen, one of the same weight from Mr. Barnes, Bicton, being fourth. Mr. Standish, Ascot, had a third prize for a good Smooth Cayenne, and he likewise exhibited, growing in a pot, a kind called "Abacachi," stated to be the most luscious of all Pines. In Grapes Mr. D. Clements took first, second, and third prizes with well-coloured good bunches of Black Hamburg; and first and second prizes for very good baskets, Mr. Hill, Keele Hall, being third. Muscats were all unripe. Mr. Cawkell was first, Mr. Horwood second, Mr. Tansley third. Excellent bunches of Foster's Seedling were shown by Messrs. Lane, and Buckland Sweetwater by Mr. Embery, gardener to J. Drew, Esq. In Peaches Mr. Horwood was first with Royal George, Mr. Turner second, Mr. Farrance third; and in Nectarines Mr. Turner had the first prize for an excellent dish, the only one shown. In Melons the best were a Hybrid Green-fleshed, and a Hybrid Scarlet-fleshed, from Mr. Enstone, gardener to Sir J. Duckworth, Bart., Wear House, Exeter; and Mr. Horwood, and Mr. Lynn, gardener to Lord Boston, were second in each class respectively. Of Cherries only two or three dishes were shown. Messrs. Jackson, Kingston, had a

second prize for May Duke. Of Strawberries remarkably fine dishes were shown by Mr. Smith, of Twickenham, and Mr. Standish. The former was first in the class for three dishes with British Queen, Sir C. Napier, and Empress Eugénie; the latter second with La Constante, very fine, Oscar, and Sir C. Napier. With the last-named kind Mr. Smith and Mr. Standish carried off the first and second prizes in the class for single dishes of fifty fruits. Mr. Horwood, Mr. Kaile, and others, exhibited good dishes, and some plants in pots were also shown. Mr. Carr, gardener to P. Hind, Esq., Byfleet, was awarded an extra first prize for a cluster of Musa Cavendishii weighing 79 lbs. He also sent several kinds of Capsicums.

## CULTURE OF ORCHIDS IN LOW TEMPERATURES.

ORCHIDS have a great deal of vitality, and are capable of bearing more rough usage than persons in general would give them credit for; in short, they are not easily killed, and will linger on a miserable existence even under the worst form of treatment. But there is a great difference between keeping them alive and growing them to perfection, and from what little experience I myself have had of Orchids I am quite sure that there are very few, if any, that can be satisfactorily grown under the cool treatment—I mean by a cool treatment a temperature such as Camellias and Azaleas like best in winter. *In medio tutissimus* is always a safe maxim, and does not mean mediocrity as some persons would aver. The "golden mean" is nearer the truth, and if any person will keep this maxim before him, and will also remember that common sense and common care are at the bottom of all good gardening, he will find that the generality of Orchids are far from being a difficult class to deal with. The cool treatment of Orchids is only a reaction from what to my mind is a far more unsuccessful plan—that of growing them in a very hot close atmosphere, tied on blocks of wood with hardly a portion of nourishment to the roots. I remember that, some fourteen or fifteen years ago, I never could see a collection of Orchids without seeing a great many poor starved specimens dragging out a miserable existence, with shrivelled bulbs and spotted leaves, wired on to baskets or blocks of wood, and I used to be told, if I remonstrated, that Orchids in their natural state were found growing on trees in tropical climates, and that this was the nearest way to imitate nature. Now, apart from the fallacy that we ought to imitate nature in cultivation, I always asserted, and still assert, that we cannot imitate a tropical climate in our Orchid-houses. It does not, however, at all follow on that account that we cannot grow Orchids quite as fine as any that are found in a natural state. It is not the science of gardening to imitate nature, but to improve upon the way in which plants are grown in a state of nature, taking nature as our guide. It has never fallen to my lot to see Orchids growing in the tropical jungles, but though the beauty of the plants is enhanced by the surrounding scenery, I am assured, and I feel tolerably certain it is true, that finer individual specimens are to be found in cultivation than those which are growing in their wild state. I am, however, digressing. I wished to add the results of my own slight experience with Orchids to the remarks which Mr. Findlay made in your Journal of the 11th ult.

Before I lived here I used to grow some Orchids in an early forcing vinery, at the warmest end, about fourteen or fifteen different species, including good specimens of Stanhopea tigrina, Coelogyne cristata, Dendrobium nobile, Pierardi, &c., Cattleya Mossiæ, Bletia Tankervilleæ, &c. The house was forced to ripen Grapes about the middle or end of July, but the Orchids had comparatively little heat in November and December. With this treatment they grew and flowered well; they seemed to like the shade of the Vines, and made rapid and strong growth. When in bloom they were taken into a cool conservatory near the house, where they continued in bloom a long time, and the colder house never seemed to injure them; Coelogyne cristata, especially, used to continue in bloom for three months. When I came to live here I built a greenhouse against the house, and seeing how well these Orchids had stood the greenhouse when in bloom, I thought I would give them a

trial here. I brought hither the very same plants, but though they grew and made bulbs with the cooler treatment they never ripened sufficiently to bloom, and after three or four years' experiment I had to give them up, as they never ripened their bulbs sufficiently to throw out blooming shoots, and it was very unsatisfactory to see each year's pseudo-bulb smaller than that of the previous one. The conclusion I am inclined to draw from this is, that any persons who have vineries for early forcing can grow Orchids in them with ease, and they will find that the actual shade of the Vines is beneficial; but it is leading persons astray to make them imagine that they can grow Orchids with any degree of satisfaction in houses such as are so commonly built for bedding plants and hardwooded plants, as Camellias, Fuchsias, &c., though there may be some kinds of terrestrial Orchids, as *Cypripediums*, and *Bletias*, which will do with comparatively little heat.

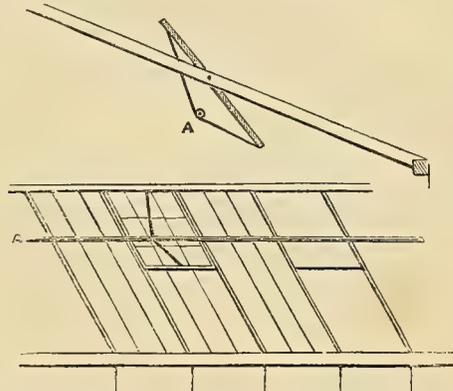

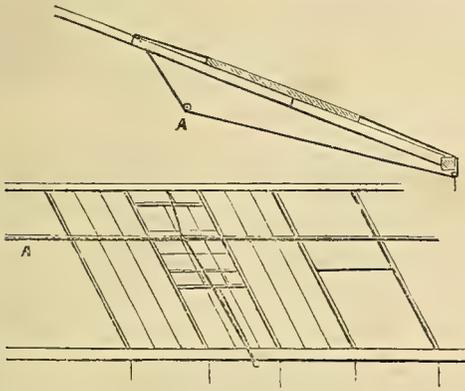

Orchids, as I have said before, are very hardy plants in their way, they will stand greater changes of climate than

most plants; as an instance of this a plant of *Stanhopea tigrina* stood the frost of Christmas, 1860, when scarlet Geraniums alongside were killed, and the same plant was accidentally left out when there was more than 10° of frost, and even then not even the younger bulbs were injured. They have, indeed, to undergo great changes of temperature in tropical climates, as I remember a cousin of mine in India, on the march near the foot of the Neilgherries, telling me his tent was frozen stiff in the morning where Orchids were growing and blooming over his head, and the temperature during the day on their march was as high as 120° in the shade; but, as Mr. Findlay justly remarks, because ice is often found on Orchids in their natural state it does not at all follow that it would be good for them in our houses, and it is no argument in favour of a generally cool treatment. I hope that others may give the results of their experience on this subject, for although I have given up the attempt to grow Orchids in a greenhouse, I am still interested in the subject.—X. Y. Z.

OPENING SASHES.

I SEND you the following sketch of an idea which, I think, may be of use. It can be employed either for sliding sash

or balance pivots. A is a simple roller suspended about 6 inches or lower from the sash-bars, and a cord, once twisted

around the bars tightly, so as to prevent any chance of slipping, is fastened at each end to the top and bottom of the sash. A crank at the end of the roller turns it, and as the rope is shortened one end is correspondingly lengthened,

the other allowing of opening, and yet preventing it opening more than one wants by wind or any cause, unless the roller go with it.—(*American Gardener's Monthly*.)

ORCHARD-HOUSE FRUIT TREES SHEDDING THEIR FRUIT.

I HAVE had a small orchard-house for two years, and this spring I have had an extraordinary show of bloom on my Plum, Peach, and Nectarine trees, but the fruit does not set well. Two or three trees of Rivers's Orange Nectarine were covered with an excess of bloom, and were blooming all through the bright sunny weather we had two and three weeks ago; but although the trees are large, and have been well established in 13-inch pots, I have scarcely a fruit on them. They had plenty of air both night and day; were well watered at the roots; the bees were always at them, so that the pollen would be well distributed; but they were never syringed until the petals had fallen.

One of my friends, whose house is filled with Apricots, Peaches, and Nectarines loaded with fruit, comforts me by telling me that the red spider last year weakened the vitality of my trees so much that they could not carry their fruit this season; but the Elruge Nectarine, and the Royal George Peach, are carrying fair crops in my house.

Another of my friends suggests that the syringing the trees with river water, when the petals had just fallen, has chilled the fruits by the water lodging within the calyx. Will you favour me with your opinion?

With regard to Plums in pots, the fruit seems to set pro-

fusely; but when it has reached the size of a Radish seed it ceases to grow, and drops off. How am I wrong here?—T. G.

[It is difficult to assign a reason for your fruit of Peaches, Nectarines, &c., dropping. Our own, against the back wall, have done so a little this season, and the blossom was very fine. We believe that if we had thinned the blossom well it would not have happened. The bees did us also a little mischief, by carrying off the pollen before it had quite done its work; but we shall have enough. The trees in pots set very thick, and we wish we could get at them to thin them. Thinning the blossom is a good plan, but we could not do so. The trees against the wall opened bloom first, and the bees worked much on them. It is bad practice to syringe too soon. We have no doubt that our large trees suffered for want of water last season. However, we shall have pretty well enough even where thinnest.]

RATS DESTROYING ROSE TREES.—Have any of your readers who are Rose-growers ever been troubled by rats? This year I had rows of standards nearly destroyed by them, until I succeeded in catching the marauder in the act. The Roses are now showing a few shoots, but some

are dead. Some of last year's budding that were not started are completely destroyed, not only the buds being gnawed out but the bark off also.—G. H.

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

*Asparagus*, the beds will be greatly benefited by liberal waterings with manure water from the stable or farmyard tank, especially where the "grass" is weak. *Beans*, as soon as the pods begin to form at the lower part of the stem top the plants, which will materially forward the podding. Earth up the successional crops after a shower of rain. *Brussels Sprouts*, prick out the early sowing to strengthen them previous to finally planting them out. *Caruliflowers*, the early crops to be liberally supplied with water; if very large heads are required manure water may be given them, but for private families those of a moderate size are generally preferred. *Cucumbers*, as they advance in growth under the hand-glasses peg them down. Water them in the morning when they require it, but this should only be done when a fine day is likely to follow. In pruning away any of the shoots and leaves cut close to the main stem; this we are aware is a disputed point, still we believe the wound heals quicker than if a piece of the stalk is allowed to remain until it gradually rots away. *Endive*, let a sowing be made directly. *Kidney Beans*, let full crops be planted forthwith. *Parsley*, thin out the plants of the early sowing to 6 inches apart; more seed may now be sown. *Peas*, continue to earth up and stick the successional crops. As soon as the early crops begin to pod supply them with plenty of water to swell the produce. At the time of sowing, during dry weather, water the drills after they are drawn and before the seed is sown. *Radishes*, sow the Long Scarlet and Turnip; water every evening during dry weather. *Savoys*, prick out some of the earliest sowing, and also the seedling plants of Scotch Kale; shade for a few days until the plants take fresh root hold. *Sea-kale*, remove the pots and also the covering as soon as done with, and afterwards dig between the plants. *Spinach*, thin the early crops, and sow again for succession. *Tomatoes*, plant out against walls. *Vegetable Marrows*, plant them out under hand-glasses. The Broccoli season being now nearly over, the stumps to be all cleared away and the ground dug, or if intended for Celery trenches, these may be prepared without digging the whole of the ground. Keep all the salading crops well watered in dry weather. As soon as the spring-sown Spinach is fit for use dig in the autumn sowing.

### FRUIT GARDEN.

This is a busy time among fruit trees, as they require almost constant attention to keep them in good order. As disbudding goes on and they are divested of superfluous shoots, let a good washing follow; this will destroy the insects, and cleanse the fruit and trees of dead flowers, cobwebs, &c. Water Strawberries in blossom, cover the rows with old pit-linings, chiefly half-rotten leaves, and water over this. Remove some of the watery wood from the Currant bushes. Thin Raspberry suckers. Attend to regulating the growth of trees designed to be trained in any particular form, stopping useless shoots to throw more strength into those that are wanted. Let water be applied by the engine every morning to Peach trees, and to others newly planted, and let the latter be kept mulched and watered at the roots.

### FLOWER GARDEN.

That the proper keeping of the garden may be as little interfered with as possible through the litter and confusion consequent on "turning out," use every despatch to bring this work to a finish; but if any portion of the stock is not sufficiently prepared, allow it to remain under glass as much longer as may be necessary, and plant out nothing but strong plants that have been carefully inured to the sun and air, for weak and ill-prepared plants are so much at the mercy of the weather that it is folly to depend upon their covering the ground in any reasonable time. Give sufficient water to settle the soil about the balls of the plants the first warm morning after planting, and give no more until the soil becomes dry, unless warm dry weather should set in, and then a gentle sprinkling every morning will greatly

benefit the plants. Spare hand-glasses will be useful now for the propagation of favourite spring-blooming plants, as Pansies, Phloxes, &c. These do best on a shady border. Evergreen shrubs recently transplanted to be watered both at the roots and overhead. Roses will require attention; it is as well to remove unnecessary shoots at once. Calceolarias and Petunias are particularly selected by slugs, the beds being frequently watered will induce these depredaters to visit them; a few cabbage leaves may be used as a trap. Dahlias, too, are liable to the attacks of slugs; a little soot round the stem will be a protection. Masses of American shrubs under or near large trees to receive a top-dressing of some kind to keep them cool, and to compensate for the exhaustion occasioned by the roots of the trees. A coating of bog earth, half-rotten leaves, or old tan will be suitable. Walls, trellises, or ornamental arcades to receive attention at this period.

### GREENHOUSE AND CONSERVATORY.

Some of the hardier stock in the conservatory, such as hybrid Rhododendrons, Camellias forming buds, and Orange trees in tubs or pots, may soon be set out of doors. This will give more room to such plants as must remain, both on account of their tenderness and the display they make. A sheltered spot should be selected out of doors, but by no means under the drip of trees. Let Pelargoniums have weak liquid manure occasionally; also Cinerarias and Calceolarias. The Chinese Azaleas, which have been some time growing, should be kept in heat until they have set their buds, when they may be removed to the open air. A stock of common and Anne Boleyn Pinks for forcing, and the flowering tree Carnations, should likewise be brought forward; the latter are valuable acquisitions.

### STOVE.

Cultivate, and forward as soon as possible, the various kinds of young stock intended for flowering through the autumn and winter. The Euphorbia jacinthiflora looks well if planted three in a pot. The Gesnera elongata should not be forgotten, nor Begonia manicata and incarnata. Some of the Justicia salicina, the Geissomeria, &c., will be useful. For Orchids keep up a large amount of moisture in the air, and syringe the blocks frequently. Every attention should now be paid to keeping down vermin; nothing short of extermination should ever satisfy the zealous cultivator.

### PITS AND FRAMES.

Roses are, perhaps, more generally admired than any other class of plants, and bloom freely in the conservatory in autumn and early winter if properly attended to at the right time. Young plants of the perpetual-flowering kinds, as Teas, Bourbons, Hybrid and Damask Perpetuals, if placed in a cold frame and properly attended to with pot room, and liberally supplied with manure water, will soon form nice-sized specimens; but in order to secure their blooming freely in autumn and early winter, the flowers must be picked off as they make their appearance, and strong stocky growth secured by giving abundance of air, exposing the plants to the night dews, and keeping the shoots stopped and tied-out as may be required.—W. KEANE.

## DOINGS OF THE LAST WEEK.

Now in most places comes the trying period of the season, in these modern times, when, in the month of May, and the beginning of June, the head of the gardener must be turned into a sort of almanack and annual register, whilst his hands would require to be magically increased some three or fourfold. Everything in-doors and out of doors is crying out for attention, and happy ought they to be who can attend to everything at once, as soon as it wants that attention. "Do it at once," is a capital axiom, and should ever be kept in mind by those who resolve on being orderly and methodical, and without orderly arrangement there will be muddle, and doing and undoing, and no little waste of shoe leather; but the difficulty is, "to do it at once," when a dozen of things want this doing, and, perhaps, only one pair of hands, and one pair of feet left to do it. In such cases, thoughtful arrangements must be made, so that whilst doing some things thoroughly, other things should not be allowed to suffer. "Cannot be done," must now be pretty well banished from the gardener's vocabulary, if he wish

to pass through life not only pleasantly, but respectably and honourably. The "can't be done" folks will soon be left behind in the race. The old gardeners who thought they worked wondrously hard some forty years ago, would find, if practising now, what with bedding-out and other work, that gardening in their younger days was mere child's play as respects labour with head and hands, compared with what it is at present.

We make it a rule to discourage all young people from taking to gardening as a profession, unless after due trial they find they have a peculiar taste and fitness for such a pursuit, have a strong relish for study and mental expansion, and are not afraid in the first place of self-sacrifice, hard living, and hard work. All the romance, picturesqueness, and poetry of the affair, without these natural aptitudes and tastes, will be apt to dwindle down into mere routine, indifference, or discontent; and we have little faith in that buoyancy which is heavily fettered with a real, or even a supposed grievance. Just as in the case of a poet, there must be natural tastes and aptitudes to form a gardener. We have boys that with slender education know every bedding plant by name, and can easily point out the difference between those very much alike. We know labourers who have worked among such plants for a quarter of a century, and though they know one plant to be a scarlet Geranium, and another a yellow Calceolaria, they do not otherwise know the name of any Geranium, Verbena, &c., and, therefore, cannot be trusted to get plants of either without these being pointed out to them. No forcing or training could ever make such a man anything more than a person who would do what he was bid. The boys, if they did not shirk the necessary application, or become self-conceited from not knowing enough, would become good gardeners.

#### KITCHEN GARDEN.

**Cabbages.**—Ours are generally very good. We grow chiefly the Vanack and Matchless. This season they do not cabbage so well as usual, growing higher and more to leaf than heart. We see, also, that there are some rogues among them. Seedsmen should be very careful of such matters, as otherwise gardeners would be forced at a loss to save their own seed. We say at a loss, because all small private growers would save their ounce or two of Cabbage or Lettuce seed at a loss, inasmuch as they could not do it for so little money as the man who saves seed as a commercial undertaking. As the plants do not cabbage so fast as we would like them, we have put strips of mat round a score or two of them, just as we treat a Lettuce, to encourage the hearting more rapidly. A young Cabbage, green outside and yellowish at the heart, well cooked, is a dish fit for an emperor. Sowed Coleworts, Onions, Lettuces, and a little more Cauliflower, the secret for a good and not wasteful succession being simply frequent sowing.

**Cauliflowers.**—Pricked out in a bed, planted a row or two, and gave a good watering with manure water to those coming in that were under glasses, and the first and second planting out of doors. The glasses from the Cauliflowers will be used to protect the first.

**Kidney Beans** that will be turned out of pots out of doors, to come in before the first sowing in the open air. These if started in the pots before planting come in early, and enable us sooner to dispense with those in pits and frames. We have a lot bearing heavily now in pits; they are grown in pots, one advantage of which is, that we can turn them out ere long and give them a little protection. There is hardly any limit to the bearing of these Beans if the pods are kept close picked, and plenty of nourishment is given to the roots. We have grown none in houses this season—in fact, our houses are too much shaded for them to do much good there, after the standard or roof-plants are in leaf. The shade is also apt to bring insects on the plants, which will trouble them little or none at all, when they can be duly exposed to light and air, and a fair use of the syringe can be made.

**Winter Greens.**—Pricked out on a north border for want of a better place, a lot of Scotch Kale, Brussels Sprouts, Broccoli, Savoy, &c. Will soon have the earth-pits, now filled with bedding plants, at liberty for this purpose. These plants will be nice and stubby, and lift with balls, as soon as other crops are cleared away. This in some cases answers better than

**Double and Treble Cropping** the ground at once, as ably alluded to at page 377, though we have followed a similar system for many years, and would do so more had we a plentiful supply of manure. We had most of our Broccoli last season planted between Peas and Potatoes. The Potatoes were first removed, then the Peas, and the ground forked over among the Broccoli—good stiff little plants which have produced compact nice heads. In spring Potatoes were planted between the Broccoli, and Peas at some 10 or 12 feet apart, digging out a trench and dunging it before sowing. Now, a good part of the Broccoli being cut, it will be taken away, the ground forked up, the Peas staked when high enough, and when cleared of Potatoes, the ground will be used for Turnips or salads, and most likely will be trenched in winter for Carrots, or thrown out in beds for Celery with Peas on the banks. We think the shade of the Peas is of great benefit to the Celery and helps to give it what it naturally wants. We generally grow the Celery in beds from 3 to 5 feet in width, and these beds, if made in time, come in useful for early Potatoes or the earliest Cauliflower before the Celery is ready. To all who have little ground, and do not begrudge a little extra labour and manure to make the most of it, we commend attention to our correspondent's article.

**Onions.**—Planted out a lot of the autumn-sown—should have been done some weeks ago—merely fastened the roots in the ground, leaving the neck and bulb out. These were planted between the rows of fresh-planted Asparagus, hardly fair to the latter however, but the roots will not reach to where the Onions are until these are taken off. In thinning for this planting moved the earth from the neck of the Onions left, and placed those not wanted in by the heels in a shady place to be used for salads; the spring-sown being as yet scarcely large enough, though just the size that some people like, who dislike them when larger than a small stocking-needle. Picked over the Onions in strings, taking out all those still hard and firm, and placing them thinly in an airy place, and turning the others growing into a trench to furnish Scallions. These are generally softer than young Onions, and for those who can tolerate the scent furnish a nice relish to the labourer with his bread and little bit of pork or bacon, if they are not wanted for other purposes. Long after this fine Spanish Onions are to be obtained in the shops in London as fresh and sound as a good Turnip. How is growth prevented in the heat of the summer?

**Turnips and Radishes.**—Sowed more in succession. A new fly seems to be committing ravages among them and young plants of all kinds this season. At least, we have not yet seen the old Turnip fly, and judge it must be another one, though we have never seen it, but we see the effects, the leaves being nibbled and holed. Wood ashes dusted over are as good as anything for keeping them away. Spruce branches stuck among the plants are also good. Watchfulness here, too, must be exercised, if the gardener would conquer his natural enemies, and he may rest assured that whatever commiseration may be felt for the farmer, when his richly-manured fields resemble a barren waste, there will be little sympathy felt for the gardener if by some means he does not produce crisp, sweet Turnips. What sort of Turnips are those which are marked in the Covent Garden report at from 3*d.* to 6*d.* per bunch? Young Turnips at one time at this season would have been worth shillings instead of pence.

**Cucumber-beds.**—You will recollect how these were made for frames. The heat has kept very regular, but began to decline a little, and, therefore, a little short grass was put round the frame, and covered with long litter, so as to afford secure footing. After such addition, care must be taken to tilt the sashes for air—that is, lift them up and not slide them either backwards or forwards. The steam from such material would be anything but relished, and hence the importance of lifting the sash and keeping it up with a notched stick or other means, and not sliding the sash up or down over such linings. The topping of these linings will be all the beds will require until late in autumn. After all that can be said, the great secret for lasting hotbeds, is to build them so that there shall be a slow decomposition of their materials, and, consequently, a slow and gradual giving off of heat from that decomposition, which is just another form of combustion.

FRUIT GARDEN.

Here the chief work has been giving some water from the dunghill to Strawberry plants, and looking after a few insects out of doors on Peaches. In the latter case the tom-tits have come in as our friends. During the last week we stood at our window at 4 A.M., and noticed a loving pair as busy as busy could be, peering into every hole and corner for green fly and a chance caterpillar. We must not sing or cry out until we get out of the wood; but it is so far fortunate, that as yet our trees under glass have shown no trace of insects. We are pretty well obliged to leave them to themselves; but they sadly want a day for stopping and thinning the branches. With every disposition to get through with work, we are more and more convinced, that very long hours are a mistake, a drag to the worker, and no benefit to the employer. Mind we do not take into account exceptional cases, and not often repeated, then a man and men rightly influenced will do wonders, but continue the long hours even with extra encouragement, and extra pay, for a week or two, and you will in the end scarcely have the usual amount of labour done. The human machine cannot go on like a steam engine, however you give material for combustion, in the shape of meat and drink. When no extra pay is given, and a great deal of extra work and late hours are looked for, not only will the exactors be disappointed, but really such cases ought to come under the cognisance of the Society for Preventing Cruelty to Animals. Mind this is altogether a different affair from a good worthy man, seeing that things want doing, and without even a hint, of his own accord he does it cheerfully after the usual hours. Such work should not be forgotten, and when a young man willingly does such things he should be able to visit a neighbouring garden without breaking in on the rest and repose of the Sunday.

ORNAMENTAL DEPARTMENT.

Have fairly begun bedding out, at least will before this is in print. Our last cuttings have done wonders in a short time in the slight hotbeds, dibbed out at once without pot or other vessel. Such a plan, and with bedding plants in general, is a great saving where you can plant out near at hand. It would not do for commercial people, or where the plants had to be carried far. The plants grown in pieces of turf turned out so well that we shall be inclined to enlarge the numbers of the plants so treated. We will just for the present allude to a few points.

1. Single beds filled with bedding plants will be most pleasing if edged with a shaded or contrasted colour.

2. Groups of beds if at all large will be more easily planted if the beds are edged.

3. In a regular group, no plan is more satisfactory than planting in pairs, either opposite or crossed. This is just on the principle that like draws to like. Many of our readers, merely for variety, do away with all attempts at pairing, and if it please them we have no right to find fault. As we have previously stated, if they choose to run a black and a white horse in their carriage, if they choose to paint one side of their carriage claret and the other yellow, and have the wheels on one side red and the other side yellow, that is their affair, and we have no right to intermeddle or to quarrel with their taste. The person that pays has the right to determine, even though there may seem to us to be a want of balance.

4. The heights of the plants in a group should be uniform, or there should be a regular gradation of height from back to front, from centre to ends, and *vice versa*. Many flower gardens, otherwise beautiful, are often marred from inattention to this simple matter. We can recollect of a fine ribbon-border near London planted on the flat, and the middle row dropped down a foot or more below the rest. The planter considered it an eyesore; but next season there were from blind imitation alone some dozens of borders and beds as low in the middle as the bottom of a deep dish when compared with the rim. In beds scattered about it matters less, but in a regular group the gradation of heights is a great point of success; and

Lastly, This gradation of height does much to economise the labour of the future treatment, and, besides, the plants look so much better when growing as nature intended them to do, instead of being twisted and layered into all unnatural attitudes and shapes.—E. F.

TRADE CATALOGUE RECEIVED.

W. Cutbush & Sons, Highgate Nurseries, London. N.—*General Catalogue for 1865-6.*

F. & A. Dickson, 106, Eastgate Street, and Upton Nurseries, Chester.—*Catalogue of Select Bedding Plants.*

COVENT GARDEN MARKET.—MAY 20.

The supplies have again much increased during the past week, both continental and home grown, but we have not much variation to report from last week's quotations.

TO CORRESPONDENTS.

\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

ROYAL HORTICULTURAL SOCIETY'S SCHEDULES OF PRIZES (F. N.).—Apply to the Assistant-Secretary at the R. H. S.'s offices, South Kensington.

ADVERTISEMENTS (A Subscriber).—You can send postage stamps.

NEW LATE WHITE BROCCOLI (W. Paul, Waltham Cross).—When we received a specimen (May 18th), the head was perfectly firm and close; colour almost as white as that of the Cauliflower; and the incurving dense growth of leaves renders it self-protecting. The head is above the medium size, and almost a globe, being nearly as deep as it is broad. These qualities render it a very desirable late variety.

GOOSEBERRY CATERPILLARS (Dalton).—Dusting the bushes with fresh white hellebore powder will kill them. Repeat the dusting until they cease to appear, and then syringe the trees thoroughly to wash off the powder.

HEATING BY ONE OR TWO BOILERS (Eskdale).—"Whether would two lots of houses, 30 yards apart, be best heated by one boiler or two? They are new houses; two, a vinery and stove in the one place, and there will be three or four pits and houses in the other." In your case we would decidedly have two boilers, as the extra expense for two boilers and extra fuel will be much less than 180 feet of piping applied to no purpose, and the heat thus lost. Besides, it is not safe doing a great deal with one boiler, unless you can have another in reserve. We know some places where the bursting or leaking of one boiler in winter would next to wreck the inmates of a number of houses, unless all sorts of extemporised stoves were resorted to.

VARIEGATED AGERATUM (H. R. C.).—The only variegated Ageratum we know, had dirty yellowish white on the leaves, and it grew from 15 to 24 inches in height. Though looking tolerably well in doors, it was ugly out of doors. The inch you sent of a variegated dwarf one, a sport from Prince Albert, if it keep true seems to be better, as, though shrivelled, the green of the leaf was blotched with a rich yellow. So far as we could judge from such a morsel, we should say it was worth looking after, but you had better send a whole shoot or plant.

FLOWER-BUDS OF PELARGONIUMS AND CINERARIAS WITHERING (Inquirer).—We should say from want of air and want of water, and then, perhaps, excess of the latter.

GREENHOUSE EVERGREENS (Radford).—We cannot occupy our space with such a list as you require, with directions for their culture. We readily give information relative to any particular plant or subject, but for general directions you had better buy "In-door Gardening," which you can have free by post if you enclose twenty postage stamps with your direction.

**SOWING HERBACEOUS CALCOLARIA SEED (*Idem*).**—The beginning of August is a good time for sowing it; and in a shady place, under a bell-glass or hand-light out of doors, the best place.

**SEEDLING PANSETS (*W. S. D.*).**—Good border flowers, but not superior or novel.

**FRAGANTHA NOT FLOWERING (*A Subscriber of Some Years*).**—The probable cause of the tree not flowering is too severe pruning, and the well-ripened shoots being cut off. To bloom freely it does not require very close pruning, and it, like every other flowering tree, produces fruit or berries at the upper part. To make it produce fruit or berries at the lower part, which is up-hill work, you may train in some young shoots, and these will flower in a year or two if not too much shaded by the neighbouring branches. We have it against a wall, which it covers completely, and as bushes on rock-work, the tree in the former case being close-pruned in order to cover the wall with green, and it does not bloom much and produces few berries; but that on the rockwork is seldom pruned, and it flowers and fruits abundantly. If you were to thin out or train the branches so that air and light might be admitted freely to the wood, and never allow the shoots to become crowded, but stop in August those which grow too rampant, perhaps buds would be formed, and the tree bloom, and produce its berries freely. We have little hope, however, of your making it produce berries at the lower part so well as at the upper part under any circumstances. Perhaps it would have flowered more profusely had it not been pruned.

**DESTROYING INSECTS (*Idem*).**—Laurel leaves will destroy green and brown aphids, thrips, red spider, and mealy bug. The way we use them is to bruise them with a mallet, and spread them on the floor or under the plants on stages in the evening, shutting up the house. The leaves are removed in the morning and the plants syringed. One bushel of bruised leaves is the quantity required for a four-light pit. Unless Laurel leaves are plentiful fumigation with tobacco is a cheaper, safer, and more certain means of destroying aphids and thrips. We have found that a handful of bruised Laurel leaves put in a can of water overnight, make a wash which few insects like, if the water is syringed over the plants in the following afternoon. We have also used them for fumigating, first bruising, and then placing them on hot cinders or charcoal in a flower-pot, and using a pair of bellows to make them burn. The house is filled with smoke, and the plants syringed in the morning. Laurel water, and the leaves both bruised and burnt, are destructive to insects, but care is required, otherwise the leaves of the plants may be seriously injured. Perhaps the most cleanly and effective of insect-destroyers is quassia water, made by boiling 4 ozs. of quassia chips in a gallon of soft water for ten minutes, and adding to it whilst hot 4 ozs. of soft soap. This, applied with a brush, will kill all the aphids family, and when syringed on the plants it kills all it touches; for syringing with there should only be 2 ozs. of soft soap to the gallon of water. Planting Potatoes in an orchard-house would not cause the trees to be infested with caterpillars, which, we presume, are what you mean by worms.

**MANURE ON VINE-BORDERS—APPLYING MANURE WATER (*Omicron*).**—The manure placed on the border in autumn should be removed at once. The only good it can do is to prevent evaporation from the surface, and keep the soil more uniformly moist. On the other hand it prevents the sun from heating the border, and the air from entering the soil. Remove it entirely and point the soil over a few inches deep, but not so deeply as to injure the roots. Liquid manure may be given with advantage during the growth of the Vines—that is, when the Grapes are well set, and once or twice a-week according to the weather. If the Vines are in an inside border it may be given twice a-week, but never, whether the border be inside or outside, until there is a necessity for it, which the condition of the border alone can enable you to determine. It would be better applied at a temperature higher than that of the soil. There is everything to fear from applying it too strong; it should, therefore, be applied weak, and not after the Grapes change colour. Unless you have some experience in its application you would consult your own interests by leaving manure water alone—at least give but few applications, as, for instance, give a good watering with liquid manure diluted with six times its volume of water the first dry weather after the Grapes set, and again when they are advanced for colouring. You will thus help them at the first and second swelling, and that will usually be sufficient for ordinary outside borders. When the borders are very narrow and very full of roots, more frequent applications may be given, and then it is necessary to dilute the liquid more than when given less frequently, and where the soil is less fully occupied with roots. We caution you against using liquid manure too often and too strong, judgment must tell when to give it, and care is needful not to give it too strong.

**MESEMBRYANTHEMUM COMPOST (*E. A. C., of C.*).**—The main point is to provide perfect drainage, either by placing stones or pieces of pots under the beds, and to raise the beds above the surrounding level. They do well in a compost formed of turves cut 3 inches thick from a pasture where the soil is light and sandy, and laid in a heap for twelve months, turned over twice, and chopped pretty fine. To three-fourths of this material add one-fourth sharp sand, and if the loam is deficient in vegetable matter one-fourth more of well-rotted leaf mould. Mesembryanthemum should have a sunny situation, and though capable of enduring drought better than the majority of plants, a copious watering during dry weather will be of service. Probably your climate is not sufficiently warm for the species that do not bloom. Perhaps if you were to pot and grow them in a greenhouse they would flower, planting them out in the summer only, or in May, and taking up early in October.

**OPHIRE ROSE ON MANETTI STOCK (*J. Caldwell*).**—This is a free-growing and good Rose but rather tender, and should have slight protection in winter. As it does not succeed with you, the soil in which it is planted is probably too highly manured, so that the roots have not taken free hold of the soil. From some cause or other it is quite certain that the plant is not healthy, and that we should attribute to the repeated applications of manure water. Discontinue these until the plant grows more freely, and water during dry weather with water only, syringing the head frequently in the evening of hot days. Remove the mulching or point it in, and keep the surface about the plant frequently stirred, but not so deep as to disturb the roots. If the plant grow no better this summer take it up in autumn, but do not cut-in the roots much, merely cut-in a little the points of those which are long and straggling. Plant in rather strong turfy loam, and place a few inches of litter on the surface around the plant as far as the roots extend. Strong applications of manure water are very injurious to a sickly plant.

**FRENCH ASPARAGUS.**—"I am at a loss to know what point Mr. Watson wishes to prove in sending you ten heads of Asparagus grown by L'Hérault, of Argenteuil. I stated most distinctly that my remarks applied to Asparagus grown on the French system in England, and that I never doubted Mr. Watson's statement as to the Asparagus of L'Hérault. I admit L'Hérault does grow very fine Asparagus, it being a question for different palates to decide whether they prefer the delicate or the full-flavoured. Beyond proving that L'Hérault is a successful Asparagus grower, and verifying Mr. Watson's account of it, the ten heads sent you go no way to prove my statement wrong. To do this it is necessary to grow Asparagus on the system of L'Hérault in England, which if it be at all like that I have grown on the same system, commonly known as the French, and like what I have eaten of the growth of others, will be as 'tasteless and as tough as the root of an Elm tree' for fully two-thirds of its length. Mr. Watson being about to produce some of this esteemed vegetable on the system of L'Hérault will be better able to tell us what it is like. It is not a question as to whether Asparagus grown on a certain plan in France is 'deliciously tender,' but whether it will be so grown on the same system in England, where the Asparagus is of full flavour, and nearly all, if not quite all, eatable if cut, as it ought to be, never below the surface.—GEORGE ABBY."

**CURATE'S VINERY (*Cast Iron*).**—Any one may construct this in the forms mentioned in Mr. Rivers's "Miniature Fruit Garden," and in our columns. Those forms are not protected by any patent. We do not recollect the reference to the patented heated process.

**GLOIRE DE DIJON ROSE LEAVES BLOTCHED (*M. H.*).**—The leaves sent were severely blotched, and this we ascribe to the excessive mulching with sheep's dung. The late heavy rains having washed the fertilising matter into the soil the roots have taken it up in excess, the leaves have become gorged, and mildew has been the result. Syringe the tree freely in the evenings of hot days, and keep well watered at the root, but avoid mulching with very rich and fresh manure, and beware of applying manure water in too powerful doses. Lessen the mulching of sheep's-dung, or, better, remove it.

**STOPPING SHOOTS OF ORCHARD-HOUSE TREES (*O. N. J., Sussex*).**—The fifth leaf is time enough to top or pinch out the terminal bud of Peaches and Nectarines in pots, and the same plan may be followed with Apples and Pears, though it is as well to let them grow a joint or two more, as topping too early causes the latent buds below to break into shoots, instead of ripening into fruit-buds.

**VINE LEAVES (*F. G. H.*).**—There is no disease on the Vine leaves, except the least trace of rust fungus from extra feeding, and a hot, moist, still atmosphere. The holes and blotches in our opinion are produced by the sun shining on the leaves when damp, and surrounded by a high moist temperature. Early air-giving is the only remedy. 100° is rather too much with so much air. With plenty of sun we like it to do the heating during the day; but 100° is rather too much, and imitates that you keep the fire too large.

**PINE CULTURE (*Pines*).**—There will be no difficulty in growing Pines planted out in a pit 24 feet by 6 feet, heated by dung and leaves only, since you can obtain plenty of those materials, and also plenty of labour. Such a pit should be from 7 feet in height at back, and from 5 feet in height at front, to a foot or two more, according as you may deem necessary. The whole might be above ground with a bank of fermenting material all round to give both bottom and top heat, the bottom of the bed being either an open chamber, or a bed formed of rough flues by clinkers, bricks, stones, &c. The bed, however, would be more easily managed if about the half of the depth were under the ground level. Whether you had an open chamber, or a chamber of flues by clinkers, you would need about half of the above depth for stiff plants, and more if very large ones. The most economical mode would be to build with single brick on bed, with nine-inch piers every 3 or 4 feet, and to make the lower part of the wall, back and front, pigeon-holed. The linings should be at least 2½ or 3 feet in width, and 3 feet at least in depth—that is, the curb should be from 6 to 12 inches above the ground level. This would secure you heat enough during the summer months, and you could obtain top heat enough in the other months by raising the linings against the walls. If you objected to this mound in winter, you would need to make the linings fully 3 feet in width, and make a flue back and front—say 2 inches wide—with slates, or tiles, to receive heat from the chamber beneath, so as to obtain a sufficiently high atmospheric temperature without giving too much bottom heat. By this means too, all steam from the linings would be completely under control, and such a pit may be managed with much neatness by means of boards to cover the linings. Where fermenting material was scarce, such a bed might be heated by the fermenting material being placed in a chamber by means of close-fitting double doors at back and front. The linings will answer the purpose very well where there is plenty of material. It should never, however, be forgotten, that one load of fermenting material shut in directly below the plants will do more than five times the quantity placed as a lining round the bed, as the most of the lining goes to the benefit of the outside atmosphere, unless the lining is itself covered-in. With abundance of material and labour, dung and leaves may do whatever hot water, or flues, or stoves can do. The chief advantage of your pigeon-holes below will be, that the moisture and enriching gases from the linings will pass beneath the bed, and if the bottom is a little open, the roots will receive the benefit. The great point is to secure enough of top heat without too much bottom heat, and to be able to regulate the dryness or moisture of the top heat at will. A nine-inch wall would be substantial. We shall publish "A Manual of Pine-culture," in a short time.

**DELPHINIUM CHINENSE (*P. P.*).**—"Will seedlings of the above (2 inches high, in second leaf, and transplanted this day, May 10th), bloom this year, that is in August next?" The plants will be hardly strong enough, but will bloom in autumn if well watered.

**SETTING A BOILER (*Eskdale*).**—There is no definite rule for the depth of a boiler, but if you are safe from water in the stovehole, the boiler will act better if some 2 feet at least below the flow-pipe in the house. Much less will do if the water should trouble you. For a length of 50 feet the flow-pipe should rise to the extreme end from 6 inches to 1 foot, and have an air-pipe there. We have, however, had them on the level, and doing well, but we favour a slight rise.

**REGENERATION OF SOCIETY (*G. Garibaldi*).**—Dividing our farms into four-acre allotments will not regenerate society. Fergus O'Connor thought it would, but he would tell you he was mistaken if he could speak from his grave in Kensal Green Cemetery.

**FLOWER-GARDEN PLANTING (N. C. Nenagh).**—In some small groups, if on grass, it often answers well to edge all the beds with white, but in such a group as yours, containing some seventeen large beds, it would tend to promote a monotonous sameness; and though blue is not, as a rule, telling against grass, yet we would have that and other colours for edgings rather than have them all of one colour. If we edged at all we certainly would edge all the groups. You seem to understand the matter so well that, instead of giving explicit directions, it will be more satisfactory to you to dwell on a few general points. 1st. Being on grass we approve of edging blue Lobelia in 1, 3, 13, 17, with Silver Queen Geranium; but Cerastium would have been better, because it could easily be kept lower than the Lobelia. 2nd. These four clumps indicate a system of opposite pairing, which is kept up in 8, 10, and 7, 11, and therefore we do not see the propriety of cross-pairing 4, 14, and 6, 12. We would make the pairs opposite, as 12, 14, and 4, 6, and continue it with 7, 11, 5, 13, &c. 3rd. We would not have the four beds round the centre clumps all filled with yellow Calceolaria, as, with the exception of 12, 6, purple Verbena, there is no particular colour to contrast with them, and for *Aurea floribunda* blue is rather a better contrast. You have 1 and 3 blue and white, why not make 2 and 16 yellow and purple, and then make 8, 10, yellow and blue? 4th. As 1, 2, 3, are the three beds next the house, one of two rules as to heights ought to be observed. Either these three beds should, if anything, be lowest; and if the beds are not level they should rise gradually, at least in the centre beds, to 16, 15, 17; or 9 in the centre should be rather the highest, and the other beds fall to either end to 2 and 16. More depends on the arrangement of heights than is generally imagined. As at present proposed, your large centre bed 9 filled with Centaurea, &c., will be the lowest, and 13 and 5 will be much higher,

leaving it, as it were, in the bottom of a basin, whilst Stella in 13, will occupy the rim. That centre No. 9, with a dwarf Geranium along with Centaurea, will be your prettiest bed. Stella in No. 5 would be too high for it when seen from the walk at the house.—R. F.

**CROSS-BREEDING VERBENAS (C. F. B.).**—To cross the Verbena, the best plan is to slit the tube so as to allow the pollen to act on the stigma. Practically the simplest plan is to place the plants you wish to cross under glass, close together, and surrounded with netting. The wind and the bees will do what will give you some trouble and require some nicety to do more thoroughly.

**CHARLOCK, &c. (A. Billimore).**—The seeds of Charlock buried deep in the soil will retain their vitality for many years, and will vegetate when brought to the surface. Oats if unbruised pass through horses un digested, and vegetate freely afterwards. There is no such thing as spontaneous generation—it is only a term for concealing ignorance of how an organised form is created.

**PEACH LEAVES CURLED (J. B. Bogd).**—The curling and blistering of the leaves of Peach trees on an open wall is attributed to their exposure to great changes of temperature; such curling very rarely occurs under glass.

**NAMES OF FRUIT (R. G. W.).**—We cannot identify the Apple you have sent.

**NAMES OF PLANTS (L. D. S.).**—1, *Pteris caerulea albo-lineata*; 2, *Orychium lucidum*; 3, *Cystopteris fragilis*; 4, *Platyloma rotundifolium*; 5, *Polypodium vulgare*; 6, *Hymenophyllum tumbridgeense*; 7, Not determinable; 8, *Polystichum aculeatum lobatum*; 9, *Polystichum capense*; 10, *Lastrea dilatata*.

### METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending May 20th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.
	Max.	Min.	Air.		Earth.				
			Max.	Min.	1 ft. deep.	2 ft. deep.			
Sun. 14	29.896	29.851	58	33	54½	53½	S.W.	.02	Overcast; very fine; fine; cool at night.
Mon. 15	29.667	29.603	58	29	54½	53½	S.	.01	Slight drizzle; densely clouded; very fine; slight frost at night.
Tues. 16	29.704	29.697	64	39	54½	53½	S.W.	.00	Very fine; cloudy; fine throughout.
Wed. 17	29.905	29.868	65	38	55	53½	S.	.02	Cloudy and fine; slight rain; overcast at night.
Thurs. 18	30.189	30.034	70	31	55	53½	W.	.00	Very fine throughout; dry air; cool at night.
Fri. 19	30.327	30.290	71	37	56	54	W.	.00	Very fine throughout.
Sat. 20	30.286	30.161	75	48	57	54½	E.	.00	Very fine; hot and dry; air very dry; warm at night.

### POULTRY, BEE, and HOUSEHOLD CHRONICLE.

#### THE WOODBRIDGE POULTRY EXHIBITION.

THAT the show just concluded has been by far the most successful of any held by this Society admits of no question, for, independently of the decided superiority of the birds exhibited as a whole in classes, or individually, the entries themselves show an addition of fifty pens beyond the aggregate of last year. This favourable result is entirely attributable to the harmonious manner in which every member of the Woodbridge Committee personally interests himself in the success of the undertaking, even as though the results were altogether attributable to his individual exertions alone. By the kindness of Major Long the Abbey Grounds have been always placed at the service of the Society, and these grounds contain specimens of the horse-chestnut of a growth but rarely met with, one especially (now in full blossom) being fully 40 yards in diameter, and of equal height—a tree which appeared to excite the admiration of every visitor. To those sightseers, also, who last week paid Woodbridge a visit, a stroll to the Seckford Almshouses situate within a stone's throw of the Poultry Show failed not to be most interesting, as being one of the most commodious and extensive range of buildings in the kingdom devoted to a charitable purpose. The whole have been erected without any restriction as to outlay, and the accommodation throughout admits not of improvement. To the aged poor, perhaps, a greater boon could not have been afforded, for not only is a happy home in their declining years placed within reach, but a small and exceedingly well-fitted church is provided for their accommodation. It is replete with every convenience, and daily services are regularly conducted, the galleries only being open to the public generally. In walking, through the graveyard attached the ages of those interred spoke strongly that such a charity was no mean acquisition to any locality, and tended to longevity. The two eldest inscriptions were each ninety-one, the youngest sixty-two, whilst the ordinary age would be about eighty-four. An additional interest was given to the scene by the fact that several pairs of Nightingales build here annually,

and by the kindness of our guide, we were introduced to a nest containing several young ones, to which the mother bird was so anxiously devoted that she actually continued her maternal duties (although three faces were gazing upon her for several minutes, within the distance of only a couple of feet), without the slightest emotion or concern whatever, nor did the male bird sing with less energy on account of our intrusion. It is evident that known security gives these birds such confidence, and thus adds a peculiar charm to the whole neighbourhood. Many of the plants are of exceeding beauty, and the grounds of the charity are particularly well kept.

But to return to the show-field. The poultry were exhibited under two extensive tents, and the arrangement of the pens was very good. Game fowls headed the prize-schedule, Mr. Fletcher, of Stoneclough, near Manchester, taking both cups, the one with a splendid pen of Black Reds, the second cup with a pen of Red Piles. The competition was capital, and the difficulty of winning, of course, proportionate. Dorkings were generally good, but undoubtedly open to much improvement in respect to condition. The *Cochins* were one of the principal features of the show, and here Captain Heaton, of Manchester, took both the principal premiums with birds of great merit, a group of Light Silver Cinnamons taking the cup, and his well-known Buffs the second place. Besides these, there were exhibited such White and Partridge-coloured *Cochins* as could easily have secured prizes, had classes been allotted to them respectively. The *Spanish* class was a very good one, and the class for Dark *Brahmas* one of the best we have seen for years. The Light *Brahma* class was not nearly so good. The *Hamburgh* classes were not equal to those met with in the northern counties of England, but much better than those of the Woodbridge Show in previous years. The Extra Variety class was one of the best in the show, and embraced all the most popular and unique breeds. *Game Bantams* mustered strongly and of good quality.

The *Aylesbury Ducks* and *Geese* were unusually good, and but for the mishap of death to a Duck during transit, for it had been evidently dead for hours, all the prizes would have gone to Mr. Fowler, of Aylesbury.

The "Emu fowls" in the selling class were a decided rarity, and drew much public attention.

The *Turkeys* were superior specimens, and the *Pigeons* were most deserving.

The competition was throughout greatly in advance of last year, in fact, as may be seen by the appended prize-list, exhibitors at Woodbridge sent birds from places as distant as Manchester, Darlington and even Dublin. With so much public support, a couple of energetic bands, and weather the most favourable that could be imagined, we cannot but congratulate the committee on the increasing success of their show, nor do we doubt but that a slightly improved prize-schedule (as now contemplated) will bring still "more glist to the mill" on future occasions.

**GAME** (Black-breasted and other Reds).—Cup, J. Fletcher, Stonedough. Second and Third, S. Matthews, Stowmarket, Suffolk. Commended, Captain T. Wetherall, Loddington, Northamptonshire.

**GAME** (White and Piles, Blacks and Brassy-winged).—Cup, J. Fletcher, Stonedough. Second, Rev. F. Watson, Kelvedon. Third, J. J. Hazell, Great Bromley, Essex. Commended, S. Matthews, Stowmarket, Suffolk.

**GAME** (Duckwings and other Greys and Blues).—First and Third, S. Matthew, Stowmarket. Second, R. Goodwyn, Woodbridge.

**DORRINGS** (Coloured or White).—First, J. Frost, Parham, Suffolk. Second, J. K. Fowler, Aylesbury. Third, H. Lingwood, Needham Market, Suffolk. Highly Commended, W. Syson, Debach, Suffolk.

**COCHIN-CHINA** (Any variety).—Cup and Second, Captain Heaton, Lower Broughton, Manchester. Third, F. W. Rust, Hastings (Buff). Highly Commended, F. W. Zurhorst, Doonbrook, Dublin (White); H. Lingwood, Needham Market (Buff). Commended, J. K. Fowler, Aylesbury.

**SPANISH**.—Cup, Captain Heaton, Lower Broughton, Manchester. Second, F. Crook, Forest Hill. Third, R. Wright, Holloway Road. Highly Commended, J. K. Fowler, Aylesbury. Commended, Mrs. Patisson, Maldon, Essex; J. H. Cuff, Cattle Market, London.

**BAHMA POOTRA** (Dark).—Cup, H. Lacy, Hebden Bridge, Yorkshire. Second, W. L. Barclay, Leyton, London. Highly Commended, J. Hinton, Hinton, near Bath; W. Hargreaves, Bacup, near Manchester. Commended, R. W. Allen, Woodbridge; R. H. Boyle, Dublin; J. K. Fowler, Aylesbury.

**BAHMA POOTRA** (Light).—First, J. Pares, Chertsey. Second, F. Crook, Forest Hill. Highly Commended, J. Pares. Commended, W. Syson, Debach, Suffolk.

**HAMBURG** (Golden-spangled).—First, A. K. Wood, Kendal. Second, Rev. T. L. Fellowes, Acle, Norfolk.

**HAMBURG** (Golden-pencilled).—First, H. Crossley, Broomfield, Halifax. Second, W. B. Webb, Stowmarket, Suffolk.

**HAMBURG** (Silver-spangled).—First, Rev. T. L. Fellowes, Acle, Norfolk. Second, W. L. Barclay, Leyton, London. Highly Commended, A. K. Wood, Kendal.

**HAMBURG** (Silver-pencilled).—First, T. J. Saltmarsh, Chelmsford, Essex. Second, Rev. T. L. Fellowes.

**ANT VARIETY**.—First, E. Pigeon, Lympstone (La Flèche). Second, J. Pares, Chertsey. Third, J. R. Pease, Darlington (Silkies). Highly Commended, J. Hinton, Hinton, near Bath (Malays); P. Edgington, Leiston, Suffolk (Normandy); R. Tate, Leeds; J. R. Morley, Woodbridge (Pheasant Malays). Commended, E. Packard, Ipswich (Crève Cœur); J. Gilbert, Ipswich (Crève Cœur).

**BANTAMS** (Game).—First, G. Manning, Springfield, Essex. Second, J. Wiggins, Stowmarket, Suffolk. Highly Commended, R. Goodwyn, Woodbridge. Commended, G. Manning.

**BANTAMS** (Any variety).—First, G. Manning, Springfield, Essex (Gold-laced Sebright). Second, J. Cullingford, Woodbridge (Sebright). Commended, Miss M. Newson, Tunstall, Suffolk.

**SELLING CLASS**.—First, J. Wright, Woodbridge (Emu). Second, E. Pettitt, Colchester (Game). Third, Rev. F. Watson, Kelvedon (Brown-breasted Red Game). Highly Commended, R. W. Allen, Woodbridge (Game Bantams, Brown Red). Commended, S. Alexander, Woodbridge (White Dorking); G. Manning (Brown-breasted Red Game Bantams); W. G. Bannister, Woodbridge (Silver Polands).

**GAME COCK**.—Prize, E. Pettitt, Colchester. Commended, S. Matthew, Stowmarket.

**DORKING COCK**.—Prize, W. G. Bannister, Woodbridge. Commended, J. Frost, Parham, Suffolk.

**BEST COCK** (Any variety).—Prize, J. Pares, Chertsey (Light Brahma). Commended, J. Wright, Woodbridge.

**BANTAM COCK**.—Prize, G. Manning, Springfield, Essex (Black-breasted Red). Highly Commended, J. K. Fowler, Aylesbury. Commended, J. Frost, Parham, Suffolk.

**SWEETSTARKS**.—Game.—Prize and Extra Prize, S. Matthew. *Dorking*.—Prize, O. E. Cresswell.

**DUCKS**—*White Aylesbury*.—First, J. K. Fowler, Aylesbury. Second, J. F. Wigg, Woodbridge. *Rouen*.—First, J. K. Fowler. Second, J. F. Wigg.

**GRESE**.—First, J. K. Fowler. Second, W. L. Barclay (Toulouse).

**TURKEYS**.—First, F. R. Pease, Darlington. Second, J. K. Fowler. Extra, R. Garrett, Saxmundham, Suffolk.

**PRESONS** (Any variety).—First and Second, E. E. M. Roys, Ashby-de-la-Zouch (Carriers and Owls). Highly Commended, J. W. Pounney, Woodbridge (Carriers); Rev. F. Watson, Kelvedon (Blue Owls); E. E. M. Roys (Powters); R. Garrett, Saxmundham; E. Brown, Sheffield; H. Bunce, Brunswick Road, Walworth (Almona Tumblers). Commended, J. W. Pounney (Powters).

**EXTRA**.—Highly Commended, J. Canham, Sutton, Suffolk (Himalayan Rabbits).

Mr. Edward Hewitt, of Eden Cottage, Sparkbrook, near Birmingham, officiated as the Arbitrator.

**HENS EATING EGGS**.—Hens may be cured of eating their eggs, by blowing out the contents of an egg, and filling it with mustard, made into a paste. Make a hole in each end

and then blow the contents out, and when filled paste paper over the hole. One taste of the mustard effects a cure.—(*Rural American*.)

## QUADRUPEDAL CHICKENS.

It may be interesting and amusing to the readers of "our Journal" to know that I possess a chicken, more than a week old, having four legs. It is in perfect health, eats and sleeps well, and can stand comfortably on two of its legs, but when it attempts to walk is apparently at a loss to find use for more than two legs, and the other two impeding its movements, the chick is quite a fixture.

Although I have bred and been amongst fowls for several years I never saw a similar freak of nature in poultry. It is a matter of great doubt whether a double-yolked egg ever produces two chickens, or even one. I have tried several, but they always turned out addled at the expiration of the twenty-one days. Is it possible that the chicken in question is the produce of a double-yolked egg, placed in the nest unobserved when the hen was sat?

I am told by a poultry-breeder of some years standing that he once had a chicken with two legs of its own and two duck's legs, and a duck's tail in addition. This enormity did not live long, probably from being unable to make up its mind as to whether it was a duckling or a chicken. My quadruped is doing well, and I hope to amuse the poultry-loving public by its production at one of our summer shows.—**CHANTICLEER.**

## ARTIFICIAL SWARMS.

So many inquiries reach me regarding the best mode of making artificial swarms, that it is pretty evident that the advantages of this process are beginning to be generally appreciated, and that bee-keepers are more and more unwilling to submit to the anxiety and uncertainty, to say nothing of that hope deferred which maketh the heart sick, so frequently attendant upon natural swarming.

Those bee-keepers who have not advanced beyond the use of ordinary straw hives, or boxes destitute of either bars or frames, cannot do better than follow the instructions given by me in No. 161 of the new series of "our Journal," by the adoption of which artificial swarming may be effected with ease and certainty. It may, however, be remembered that "PHILISCUS," in answer to whose inquiry these instructions were given, objected that the removed hive might suffer too great a shock from the desertion of the whole, or nearly the whole, of its adult population, and that my friend Mr. S. Bevan Fox, whilst fully approving of the plan recommended by me, admitted that in the course of his practice instances of this character had occurred. I have, therefore, recently adopted the plan of confining the bees of the removed hive until after dark in the evening of the day on which the operation is effected, and find that this precaution effectually mitigates the evil complained of. As free ventilation during their imprisonment is absolutely essential, the best mode of confining the bees is by tying the hive up in a piece of cheese-cloth and suspending it in a cool dark cellar. As bees are extremely impatient of confinement at this season, it is best to place the hive in its new position and give them their liberty the same evening, merely deferring it until it is too dark for any to take wing.

Those more advanced apiarists who have adopted moveable-comb hives, and are desirous either of propagating Ligurians or rapidly multiplying their stocks, will find it very advantageous to make use of what have been styled "nucleus boxes," and start a number of "nuclei," or small artificial swarms, in them. These nucleus boxes should be of such a size as to accommodate four combs on the bars or frames in ordinary use in the apiary, and should be fitted with floor and crown-boards. It will be found advisable to screw the latter to the box, whilst for the convenience of frequent examination the crown-boards may be loosely laid on without fastening of any kind. A "duchess" slate, 12 inches by 24 inches, forms a cheap and effective protection from rain and sun, whilst its weight keeps the crown-board close and prevents its being readily dislodged by high winds.

In order to stock a nucleus box a strong stock in a bar or

trame-hive should be looked over until the queen be discovered on one of the combs. This being carefully set aside and remaining undisturbed, one of the other combs is selected containing brood in all stages from the egg to the sealed nymph, and this with the adhering bees must be placed in the nucleus box into which the bees from two other combs of the same hive should be brushed with a feather, and a spare comb having been placed on either side of the brood-comb the whole must be shut up, and (ventilation having been duly cared for), conveyed to a dark and cool place until after sunset, when it should be put in its place in the apiary, and the bees set at liberty.

If the object be to Ligurianise an apiary the vacancy in the parent stock should be filled up with a brood-comb from a black colony, and if this can be done, the abstraction of bees will (as stated in reply to my esteemed correspondent "W. L."), scarcely be missed, and may be repeated almost *ad infinitum* about every other day; but every comb of black brood should be marked with the day of the month on which it is inserted, and not employed for breeding Ligurian queens until say twelve days afterwards. If brood-combs are unattainable, or the object be not to multiply Ligurians, the place of the one abstracted should be occupied by an empty worker-comb, which will be rapidly filled with eggs; but if no worker-comb be attainable the remaining combs must be brought together and the vacancy left on one side.

Towards the afternoon of the day following, the newly-formed nucleus should be examined, with the view of ascertaining whether it possesses sufficient bees to raise a queen and hatch the brood. At least both sides of the brood-comb should be well covered with bees, and if such is not the case, another comb must be lifted out of the parent hive, and the absence of the queen having been insured by first ascertaining her presence on a different comb, the adhering bees should be brushed into the nucleus. Most of the adult bees will speedily desert the new for their old habitation, but enough young ones that have never taken wing must perforce remain to constitute an important, and probably a sufficient, addition to the population of the juvenile colony. Royal cells will soon be started, and on the ninth or tenth day all but two of these may be removed to assist in forming other nuclei, which will thereby gain a great advantage in point of time. They should be cut out with a triangular bit of comb attached (apex downwards), and inserted in a similarly-shaped hole cut in another brood-comb, whilst the greatest care should be taken to avoid bruising or chilling the royal embryos.

Fourteen days from the formation of the nucleus is the average time occupied in rearing a queen, whose first business is to destroy such of her royal sisters as are yet in embryo, and fourteen days more generally elapse before she begins egg-laying. These periods vary, of course, with the state of the weather and other circumstances, and I have even known a queen hatched so late as the twentieth day, but that which I have stated is the time usually occupied. If all go well, the population will by this time have considerably increased by the hatching out of all the brood, and as soon as eggs are laid another ripe brood-comb should be added. In a few days a fresh accession of numbers will take place from this source, when the colony may be shifted into a hive of the ordinary size, when by the judicious addition of another brood-comb or two and a few empty combs, aided by the breeding powers of the juvenile matron, it may be rapidly built up into a strong stock.

By repeating this operation as often as the number of hives in the apiary will admit without unduly weakening the stocks themselves, and taking care at the same time to utilise all superfluous royal cells, a more rapid rate of increase may be attained than by any other method known to—A DEVONSHIRE BEE-KEEPER.

#### RESULTS OF STORIFYING.

YOUR esteemed correspondent Mr. Bevan Fox seems to have misunderstood my communication in No. 200 of your Journal, detailing my apiarian proceedings last summer; as he appears to have the impression that the storified hives yielded an average of 35 lbs. each, and also furnished me with swarms. It will be seen, on reference to the article referred to, that out of six stocks kept through the winter

three were managed upon the storifying system, and three devoted to the formation of swarms. Two of the storified hives sent out swarms, which were, however, promptly returned, and royal cells excised to prevent a second issue. These hives therefore were practically prevented from swarming. The third hive did not attempt to swarm.

The three together yielded over 100 lbs. of very pure honey in supers, but the stock hives were left in a very impoverished condition and required liberal feeding to enable them to stand the winter.

All the prime swarms from the three hives devoted to swarming did very well, and from two of the stocks second swarms were also artificially raised. The prime swarms in every case sent out maiden swarms, which were returned after the royal cells had been excised. All the prime swarms and the parent hives were very heavy in the autumn, and required no feeding; although in the autumn 10 lbs. of fine honey was abstracted from one of the stocks, and nearly as much from one of the swarms. From another of the swarms I removed more than 10 lbs. of honey in the spring, still leaving the bees an ample supply for their own consumption. The swarms and stocks from which they issued (with one exception), proved much more populous in the spring than the stocks which had been storified.—J. E. B., *Wolverhampton*.

#### EARTH CLOSETS.

THAT the public owe a debt of gratitude to the Rev. H. Moule cannot be disputed, and, therefore, it may seem ungracious to say anything in disparagement of his patented earth closets; but having had one in use for some time, truth compels me to state, that although well supplied with earth, both fine and dry, the machinery has often refused to act. On one occasion a small piece of wood had got among the earth. On other occasions no cause was known. It appears to me that if the earth were simply poured out from a jug, and the closet constructed without any machinery whatever, the result would be more satisfactory, and the construction cheaper. My only regret is, that this suggestion may lessen the pecuniary advantages, which may fairly be considered due to Mr. Moule for his valuable discovery.—G. S.

THE BEE AS A PHYSICIAN.—In Marktstett, Lower Franconia, Bavaria, in the autumn of 1864, a bee is declared to have become an M.D.! Its owner, who was deaf, was stung by it in the eye-lid near the temple. He applied earth and water to the wound without effect, but at last fell sound asleep. When he awoke the church clock struck. He listened with surprise and counted the strokes. All right! The clock struck, and the bee-sting had given him back his hearing, which he had lost two years previously from the effects of a severe cold.—(*Regensburg Gazette*.)

#### OUR LETTER BOX.

FOWLS DISORDERED (*An Amateur*).—Loss of appetite and dark combs are not sufficient particulars to enable us to recommend a remedy, for they may be caused by over-feeding, or organic disease. Give each a tablespoonful of castor oil, abundance of green food, and no hard corn. They are probably too fat.

ADDRESSES (*John Cowburn*).—If you enclose to us a letter, in a stamped envelope, we will direct and forward it to "A Renfrowshire Bee-keeper."

FOUL BROOD (*W. T. Lanarkshire*).—The piece of comb appears to be infected with virulent foul brood. If the stock be populous, the mode of cure recommended by Mr. Woodbury, in No. 123 of our New Series, might be tried. If weak we should kill the bees, and make the most we could of the contents of the hive, keeping the whole out of the reach of other bees.

DROWN KILLING (*A Lady Bee-keeper*).—The recent unfavourable weather is the cause of the premature expulsion of drones in one of your hives.

PLACING A NATURAL SWARM IN A STEWARTON-HIVE (*H.*).—A natural swarm may be hived at once in the stock-box. The intervention of a common hive is only necessary in the case of a forced swarm, and that merely because it is more convenient to drive bees from an ordinary hive into one of the same form, rather than into an octagonal box.

EARLY EXPULSION OF DRONES (*A. S. A., Stamford*).—The untimely destruction of drones and drone-brood is owing to unfavourable weather, and indicates that all preparations for swarming are abandoned for the present. The return of fine weather may induce the bees to renew these preparations, but the probability is, that the issue of a swarm will be much delayed, if not altogether prevented, by the check which has been given to the prosperity of the colony.

SMALL DRONES (*M. S., Brixton*).—Some of the bees accompanying your letter are ordinary workers, whilst others resemble small drones brood in worker cells, but they reached us in too mutilated a condition to admit of a positive decision. The recent unfavourable weather is the cause of drones being expelled from the non-suppered straw-hive.

WEEKLY CALENDAR.

Day of Month	Day of Week.	MAY 30—JUNE 5, 1865.	Average Temperature near London.			Rain in last 38 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock after Sun.	Day of Year.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 68.9°, and its night temperature 45.1°. The greatest heat was 85° on the 3rd, 1846; and the lowest cold, 32°, on the 31st, 1857. The greatest fall of rain was 0.91 inch.

PROPAGATION OF THE FIG.

IG trees are raised from seed, and propagated by grafting, budding, layering, suckers, cuttings, and eyes. From seed there is a faint chance of new sorts, but the fruit, from its very nature, seems to be scarcely susceptible of improvement by cross-breeding. The seed should be taken from the pulp when the fruit is fully ripe, washed, dried, put away in paper until spring, when it may be sown in sandy loam, just covering the seeds, and plunging in a hotbed of 75°. When the seedlings are sufficiently large to handle pot-off singly in 32-sized pots, and keep them in a vinery until autumn, shifting them, however, into 24-sized pots in June, and keeping them well watered during the summer. In future seasons they should be kept pot-bound, and closely stopped to five joints, or if there be room on the garden walls they may be planted on the south aspects only, and they will grow like Willows. It is a pity to take up much space with

them, for they will not produce fruit in less than three years if grown in pots in a vinery; and I never could induce them to ripen fruit on walls in less than six, though very closely stopped and root-pruned. The readiest way of inducing them to fruit is to insert eyes, as in budding Roses, in an old tree on the trellis at the back of a vinery, in the July of the same season as that in which they are raised. In this way they will occasionally fruit in the second year, but more generally in the third. Cuttings may likewise be taken and grafted on an old plant just when it begins to grow, the scions being dormant or their vegetation not so forward as that of the stock. Where there is no old plant on which to graft or bud, I have worked on year-old trees from eyes, discarding the seedlings when the grafts or buds had taken. It is astonishing what an influence the stock has on the graft or bud, either soon arriving at a fruiting state. I have raised Figs from seed, but have only had two worth their room, and one I have discarded, having another which I consider an acquisition, it being a White Ischia in part and in part a Brown Turkey. One remove further and it will be a White Ischia with the charac-

teristics of the Brown Turkey. Beyond the desirability of obtaining new kinds there is no advantage in raising from seed.

By grafting and budding, an old-established tree may be given a new head in a short time. Tongue-grafting is the best mode when the shoots of the stock are little thicker than the graft; cleft and crown-grafting are better when the branches of the stock are thick. Beyond changing an undesirable for a better variety without losing time there is no advantage in grafting and budding, for every shoot will make a cutting, and every bud a plant; half a dozen plants may be obtained from buds to one from grafting, and instead of one plant from a cutting half a dozen may be had from eyes.

Fig trees may also be raised from suckers, but these are not so good as layers, for suckers receive a great check when detached, and are apt to throw up suckers after they become plants. They should be taken off in autumn with roots attached, and either potted or planted at once in the places where they are to remain, or planted a foot apart by a south wall to gain strength, cutting them down to three eyes in the spring if they are to be trained to a wall or trellis, and not stopping them if standards are desired.

For layering select the shortest-jointed wood; avoid that which is long-jointed. The operation is best done in pots, bending the shoot over the pot, pegging it down in the centre, and fastening the point of the shoot to an upright stake. An incision is not necessary, though one may be made at the upper side of the shoot, and immediately below a joint. With a knife remove all the eyes that would be buried in the soil, and rub out all others up to 9 inches or 1 foot for dwarf standards, stopping or pinching out the leader three joints above the disbudded part, leaving five, however, if the wood is short-jointed. If the plant is intended for a trellis or wall, leave three joints or cut down to that, and if for a standard of any height, disbud to the required height, not stopping the leader until from three to five joints above the required height. In pegging the shoot down into the soil be careful not to break it, and the same careful attention is needed in tying the shoot upright. If the weather is dry and the operation performed out of doors, water copiously. The soil should, of course, be kept moist under glass. If layering is done in spring the layers will be well rooted by autumn, and should then be detached, potted if intended to be grown in that way, and wintered in a cool house or shed; or if required for planting against walls or trellises this may be done at once.

Cuttings a foot long, taken off with a little heel of the old wood, may be potted singly in 32-sized pots with the heel close on the drainage, and then headed down so as to leave but one or two joints above the soil, picking out the eyes at the base of the cutting so far as it is inserted in the soil. Such cuttings placed in a hotbed and duly watered will grow, and when rooted may be removed to a vinery. The best time to put them in is spring, just before they begin to grow, though they may be taken at

any time after the leaves fall, and be kept with the ends in soil until wanted for grafts, cuttings, or eyes. The plants from cuttings may be planted out of doors in July, previously hardening them off a little; or they may be planted under glass or kept in pots, shifting them in July into 24's, and again, when the leaves change, into eight-inch pots for fruiting another season in pots in unheated houses, or for forcing.

The best system of propagation is by eyes. These are made in precisely the same manner as Vine eyes, and are inserted upright in 48-sized pots in sandy loam, and with the upper end of the eye buried half an inch in the soil. They should be placed with the eye in the same position as when it was attached to the plant. If laid flat the shoot will not come erect from the eye, but take an oblique direction, and an undesirable twist or turn is thus given, if a straight stem is wished. If the pots are watered and placed in a mild bottom heat of from 75° to 85°, a top heat of 60° or 65° from fire heat, and the soil kept moist, the shoots will soon appear and roots will quickly form. Keep the soil moist, and besides maintaining a moist atmosphere sprinkle them overhead twice daily, morning and evening. When the plants are well rooted remove them to a vinery or any house with a little artificial heat, which is necessary to obtain plants quickly of a size for bearing, but any house will do, though the plants will not be so soon fit for producing fruit, and they should have the warmest part of cool houses. They may also be planted out against south walls in June after hardening them.

If dwarf trees are wanted, with the finger and thumb pinch out the point immediately above the fifth leaf, and side shoots will be emitted; disbud to three on the uppermost, leaving one on each side and a leader. When these have made five leaves pinch out the ends, and we have three shoots on each, all the rest being rubbed off, and we have the foundation of a tree to be trained fan-fashion. If a tree on a stem 9 inches or 1 foot high is the object in view leave the leader alone and disbud all shoots that come along the stem, and if a standard with a longer stem be desired disbud all the side shoots up to the required height, and pinch out the leader three joints above the part disbudded. If fruit show rub it off at once, and when the shoots come, whether it be the same year as the plant is propagated or afterwards, and they have a tendency to grow erect, tie them down to make horizontal growth and a good-shaped head, stopping them at the fifth leaf. Disbud the shoots where they come too close together, stopping them again when they have made five joints or leaves, but do not stop the midsummer shoots, and only the first shoots should be stopped.

In the above manner dwarf and standard Fig trees for walls and trellises can be had in a short time for growing in cool houses (those not artificially heated), for walls, and for forcing, and a few hints on their culture will shortly be given.—G. ABBEY.

#### NAMING RHODODENDRONS.

VARIOUS articles have appeared in this Journal as to the soil and culture desirable for the Rhododendron, but I have for a long time expected to see in your columns some remarks on another part of the subject—the nomenclature of a plant that has risen, and justly so, into such high repute. The Rose has long and properly been styled the Queen of Flowers, the Rhododendron is with as much justice entitled to be styled the King of Flowering Shrubs. The increase of new varieties is now very considerable, from the number of persons who have turned their attention to the subject of hybridising, and the facility with which seedlings are raised. We have yearly accessions of new sorts to the numbers already under cultivation, and should matters go on as at present, in regard to nomenclature, we must shortly get into great confusion unless the names of the raisers be given with the adopted name of the variety.

What has led me to notice this is that I have had experience of what is heretated. I cultivate upwards of 200 choice named varieties, and in making my collection I purchased from a respectable nurseryman a plant of Prince Albert, and a duplicate of what should have been the same from another equally respectable party, but they are totally different

sorts. From another vendor I obtained a plant of Leviathan; this I expected to be a fine white, tinged rose, but it turns out to be a plain red. In both cases I complained, but by both parties whom I blamed for sending me what was not the variety wanted, I was told there were two varieties of that name, and I believe both the sellers might be perfectly honest. As an instance, three or four years ago I exhibited at the Roxburghshire Society's Show, in April, a seedling which had a first-class certificate and was that day named *Mirabilis*. In May succeeding one of the Bagshot nurserymen, I think it was Mr. Standish, exhibited a seedling at one of the London shows, and named it *Mirabilis*. This I only knew by reading the report of the show. I did not, of course, alter the name I had given, but added Deansi to it, which would prevent any one purchasing from thinking he was having what was not the variety intended in both cases.

What I should think is now absolutely necessary is, that all new sorts should have the raiser's name succeeding the name of the variety, as in the case of Dahlias, Hollyhocks, Carnations, &c. Nurserymen in printing their catalogues should aim at this, and give the raiser's name or the person sending the varieties out, so far as known, but I have seen no attempt at this, except in one instance, that of Mr. Veitch of Chelsea, in advertising the seedlings raised by his late father.

I raise thousands of hybrids and have a few good varieties amongst them, but I should feel annoyed at sending them out with names which, unknown to me, were adopted by others. Give the raiser's name, and then the public know what they buy, and raisers are free of all blame for what they sell, if these suggestions are acted on. It is only what the public are entitled to.—W. DEANS, *Jedburgh, N.B.*

#### ROYAL HORTICULTURAL SOCIETY.

IN accordance with the Minute of Council of the 16th May, 1865, the Fruit and Floral Committees met the Council on Monday, May 22nd, when the following resolutions were unanimously carried—viz.,

Proposed by Dr. Hogg, seconded by Mr. Moore, and unanimously carried:

"That in future, for the year 1866, Special and Great Shows, at present held on Saturdays, shall be held on some other day of the week."

Proposed by Mr. Lee, seconded by Mr. Wm. Paul, and unanimously carried:

"That this Meeting recommend that the Fruit and Floral Committees on Tuesdays, should meet at 11 o'clock, and the plants be removed not earlier than 5 o'clock p.m., and that exhibitors are earnestly requested to send all objects for exhibition before half-past 10 o'clock, a.m."

#### VINE CULTURE—STOPPING THE SHOOTS.

I HAVE a Vine spur-pruned showing fruit on nearly every shoot. Should these shoots be stopped, leaving one joint between the bunch and where nipped off? and when the laterals break at the bottom of the leafstalks after the above stopping, should they be taken clean off, or should I allow one joint, a leaf, &c., to remain? If the Vine is very vigorous, and say four years old, and bears on every shoot, will it be likely, when cut back on the spur-pruning system next season, to produce fruit again on each shoot?—A. B.

[As the question you have asked is one of great importance to many amateurs just at this time, I shall enter more fully into details than I otherwise would have done. In doing so I shall describe the operation of stopping or pinching the Vine, and add a few instructions for its management afterwards, in a plain and intelligible manner, so that those not acquainted with the management of the Vine may be able to cultivate it successfully with pleasure and profit.]

In the first place, I shall suppose your Vines to have arrived at that stage of growth when they would require stopping. The proper time to do this is when the shoot has made three joints above the bunch, then pinch out the uppermost joint, leaving two joints between the top of the shoot and the bunch. The reason of my advocating leaving the shoot till it has made three joints above the fruit joint

is, because the young leaf on the second joint is very frequently injured if the point of the shoot is pinched out as soon as the second joint is made; but if left a few hours longer the point of the shoot can be pinched out without doing any injury to the leaf on the second joint. The two first leaves that are formed above the fruit joint must not on any pretence whatever suffer any injury by mutilation or otherwise, as they are the main lungs through which the Vine receives its atmospheric food, which is immediately conveyed to the bunch. In a few days after the first stopping, the shoots will throw out laterals or side shoots, these should be stopped at the first joint. By this time the Grapes, if all go on well, will be in flower. If the weather is favourable give all the air you can to disperse the pollen. If it is too cold to give air you must create a current artificially; the best mode of doing this is to use a thin piece of board about 2 feet long, and a foot or 18 inches wide, and by waving this to and fro the pollen is easily scattered about. In giving air always avoid direct currents, unless the air outside is very mild, and the wind not too high. Always open your front and back lights alternately. If they are opened opposite each other a sharp current of air passes through the house, which often rusts the young Grapes, and gives them a severe check, from which they do not soon recover; in fact, this often disfigures them for the season.

*Thinning the Fruit.*—This is a delicate operation, and should be performed with great care. In the first place see that your scissors are sharp at the point. Secondly, be careful not to rub the berries with the scissors, the points of which should not be wider apart than is necessary for taking hold of the fruit-stalk. Commence the operation of thinning as soon as the fruit is fairly set; the berries that ought to be cut out are every day impoverishing those that should remain. In thinning the bunch endeavour to carry in your mind's eye the size the berries will be when ripe, and thin accordingly. Leave the berries all over the bunch regularly distributed, so that the bunch when ripe will be filled out, having no open spaces, but every berry in its proper place. With a little practice and proper attention this may be done at the first thinning; in fact, there ought to be but one thinning. After the operation of thinning is finished, and the young Grapes are about the size of Peas, all the lateral shoots that are made above and below the fruit joint should be pinched out, so that the whole force of the Vine may be directed towards the fruit. The Vines should not be syringed after the bunches are formed. Proper directions for this will be given in some future paper on pruning and starting the Vine into growth. The syringe must only be used for sprinkling the floors and stems. After the Vine has set its fruit, the next operation will be

*Shouldering the Bunches.*—This is done by fastening small strips of matting to the shoulders of the bunches, and drawing them slightly away from the main part of the bunch, and fastening the other end of the strip of matting to the trellis or any convenient spur of the Vine, this allows the air to circulate freely through the bunch, and if this operation is performed judiciously, the shape of the bunch will be improved, it also acts as a support, especially when the bunch is large. From the time of thinning the Grapes till they begin to form their stones or seeds, the temperature of the house should never be lower than 60° by night, and from 70° to 75° by day. If the temperature rise to 80° or 90° with the sun, it will do no harm, providing there be plenty of air on at the time. Shut the house up about 2 or 3 p.m., in bright weather, earlier if it is dull and cold. Pay great attention to giving air, and shutting it off; for instance, if the sky become cloudy suddenly, partly shut up the house, and if the sun come out again soon afterwards open the lights as soon as possible. Fine Grapes cannot be grown unless proper attention is paid to this particular and most essential part of the work connected with Grape-growing.—J. WILLS.]

(To be continued.)

#### VEGETABLE VARIATIONS.

"T. G. H." sent you, a short time since, an extract from the "Naturalist," on a "curious effect of grafting," which has since been illustrated by "E. S." A very curious case in point came under my notice last summer.

In the garden of a friend in the neighbourhood of Bath, are two Laburnum trees, the pink variety, with short full racemes. In both of these trees were sundry branches of pure yellow blossoms, and all over the trees were bunches of blossom containing one long yellow raceme in the midst of short pink racemes, and *vice versa*.

But the strangest fact remains. High up amongst the branches were tufts of quite a different Broom-like plant with pink blossoms. They were too high for me to ascertain the genus and species to which they belonged, but they appeared of a more prickly character than any Broom with which I am acquainted.

The trees were old ones, and my friends were unable to throw any light on the manner in which they had been grafted or budded, it having been done by a former inhabitant; but for the ten years they resided in the house the characteristics of these trees have been constant.—ELLA.

#### ROYAL BOTANIC SOCIETY'S SHOW.

MAY 24TH.

THE first great Show was held on Wednesday last, and well did it sustain the high reputation which the Regent's Park Exhibitions have long maintained for that freshness and brilliancy which nowhere else exist in an equal degree. Indeed, it may safely be said that for extent and general effect it has never been surpassed by any show at the same season. Not only were the stove and greenhouse plants most worthily represented, but there were gorgeous Orchids, gigantic Azaleas, Roses such as have been rarely equalled, and wonderful Pelargoniums, whilst the lofty Palm and the lowly Fern helped to swell the train.

STOVE AND GREENHOUSE PLANTS.—Many good collections were shown, but the plants were nearly of the same kinds as those which have appeared at our exhibitions for the last three or four years, and this constant repetition becomes wearisome. It is high time that other species should be added to the somewhat limited list of those at present grown for exhibition purposes. In collections of sixteen Mr. Peed again showed his fine *Allamanda grandiflora*, a large *Erica depressa*, a fine bushy plant of *Ixora Griffithi*, a fine *Chorozema*, and two good *Pimeleas*. From Mr. Whitebread came *Allamandas*, *Aphelexes*, *Azaleas*, *Heaths*, the showy scarlet *Clerodendron splendens*, *Rondeletia speciosa*, and a good *Stephanotis*; and from Messrs. Lee a fine *Acrophyllum venosum*, a large bushy *Erica depressa*, *Ixora coccinea*, a fine *Stephanotis*, and *Aphelexis macrantha purpurea*, very bright in colour. Mr. Baxendine sent a *Hoya Paxtoni*, a pretty plant, but from the drooping habit of the flowers it does not show to advantage unless the pot be tilted. *Clerodendron Thomsonae* and *Rhynchospermum jasmoides* were also shown in the same collection; but of the former by far the finest specimen in the show was that from Mr. Fraser, though it was not fully out, being in this respect surpassed by one from Mr. A. Ingram, in which the scarlet corolla formed a beautiful contrast with the snowy white calyx. A magnificent plant of *Prostanthera lasianthos*, measuring some 5 feet high by as much in diameter, was also shown by Mr. Fraser, as well as good plants of *Adeandra fragrans* and *Erica Bergiana*. A fine bushy *Rhynchospermum* was also shown by Mr. Ingram, and in other collections we remarked several good *Aphelexes*, *Allamandas*, *Heaths*, *Combretum purpureum*, and *Chorozemas*. In mixed collections of flowering and ornamental-foliaged plants Messrs. Lee again exhibited their fine *Alocasia metallica*, a noble plant of *Cibotium princeps*, *Theophrasta imperialis*, and *Cordylne indivisa*, very fine, and the variegated *Ananassa sativa* which, bearing a fair-sized Pine Apple with a variegated crown and several offsets from the base of the fruit, had a remarkable appearance; Mr. Williams's collection comprised *Azaleas*, *Heaths*, *Crotons*, *Colocasia albiviolacea*, the stalks of the broad foliage having a violet tinge with yellowish variegation; the pretty purple and white *Statice profusa*, and a beautiful plant of *Gleichenia semivestita*. From Messrs. A. Henderson came a fine plant of *Medinilla magnifica*, a basket of the showy red and black *Clianthus Dampieri*, *Vincas*, a large *Caladium*, and fine plants of *Crotons*, *Rhopala De Jonghi*, and *Alocasia macrorrhiza variegata*, the leaves largely splashed with white.

Prizes.—For sixteen: first, Mr. Peed, gardener to Mrs. Tredwell, Norwood; second, Mr. Whitebread, gardener to H. Collyer, Esq., Dartford; third, Mr. Kaile, gardener to Earl Lovelace. For ten (nurserymen): first, Messrs. Lee; second, Mr. Fraser; third, Mr. Rhodes; fourth, Mr. Baxendine. For ten (amateurs): first, Mr. Chilman, gardener to Mrs. Smith, Epsom; second, Mr. Page, gardener to W. Leaf, Esq., Streatham; third, Mr. A. Ingram, gardener to J. J. Blandy, Esq., Reading; fourth, Mr. Carson, gardener to W. R. G. Farmer, Esq., Cheam; fifth, Mr. G. Wheeler, gardener to Sir F. Goldsmidt, Bart., Regent's Park. For six: first, Mr. Kemp, gardener to Earl Percy, Albany Park; second, Mr. J. Wheeler, gardener to J. Phillpot, Esq., Stamford Hill; third, Mr. C. Smith, gardener to A. Anderson, Esq., Lower Norwood; fourth, Mr. Young, gardener to H. Stone, Esq., Leigh Park. For fifteen fine-foliaged and flowering plants: first, Messrs. Lee; second, Mr. Williams.

ORCHIDS constituted one of the grand features of the Show, a magnificent bank of these flowers filling nearly the whole of one side of the great tent. It would be almost an endless task to enumerate the species of which the numerous collections were composed. Foremost among the collections of twenty were Mr. Baker and Mr. Bullen. The former had good *Phalenopsis*, including *Schilleriana* with eighteen fine flowers, *Saccolabium retusum* and *curvifolium*, the latter with ten spikes; a pan of *Cypripedium barbatum superbum* some 3 feet across, *C. villosum* with half a dozen blooms, fine *Vandas*, *Trichopilia crispa* very fine, *Lælia purpurata*, *Cattleya Mossiæ*, *Dendrobium nobile* and *Lindleyanum*, and *Sobralia macrantha splendens*. Mr. Bullen had a splendid *Dendrobium densiflorum* upwards of 3 feet across, bearing numerous beautiful spikes of its orange bloom, by far the finest specimen in the Show; *Cypripedium Hookeræ*, *C. barbatum superbum* with some forty blooms, *Saccolabium guttatum* with eight spikes, *Vandas*, *Calanthe veratrifolia*, *Cattleyas*, &c. Mr. Page sent, among others, *Cypripedium Stonei*, the well-known *Dendrobium nobile*, and the large white-and-orange-flowered *D. formosum giganteum*. In the other classes Mr. Penny sent *Trichopilia crispa* very fine, *Cypripedium caudatum* with three flowers, the charming *Odontoglossum phalenopsis*, and good *Saccolabium*; and from other exhibitors came *Cattleya Acklandiæ*, *Chysis Limmingbi*, *Cyrtopodium punctatum*, good *Dendrobiums*, *Oncidium*, and *Saccolabium*, *Cattleya Mossiæ*, from Mr. Wilson, with large flowers, very fine in colour; and the new *Phalenopsis Lüddemanniana* from Mr. Wilson and Mr. Robson—that of the latter with four good-sized blooms.

Prizes.—For twenty: first, Mr. Baker, gardener to A. Bassett, Esq., Stamford Hill; second, Mr. Bullen, gardener to A. Turner, Esq., Leicester; third, Mr. Page; fourth, Mr. Peed. For twelve: first, Mr. Penny, gardener to H. Gibbs, Esq., Regent's Park; second, Mr. Wilson, gardener to W. Marshall, Esq.; third, Mr. Young, Leigh Park; fourth, Mr. A. Ingram. For six (nurserymen): first, Messrs. Jackson, Kingston. For six (amateurs): first, Mr. Wiggins, gardener to W. Beck, Esq., Isleworth; second, Mr. Wheeler, gardener to J. Phillpot, Esq.; third, Mr. Chilman; fourth, Mr. Robson, gardener to G. Cooper, Esq.

HEATHS.—Among these were nice specimens of the showy scarlet *Westphalingia*, *ventricosa magnifica* and *ventricosa coccinea minor*, *elegans*, *tortuosiflora*, *tricolor flammea*, *Albertus*, buff, *Sindryana*, *denticulata moschata*, remarkable for the flowers coming mostly in fours united at the base, *Victoria*, *eximia superba*, the pretty blush white *perspicua nana*, and many others.

Prizes.—For ten: first, Mr. Rhodes; second, Messrs. Jackson; third, Mr. Baxendine. For eight: first, Mr. Peed; second, Mr. Page. For six: first, Mr. Chilman; second, Mr. Wheeler, gardener to J. Phillpot, Esq.; third, Mr. C. Smith, Norwood, and Mr. A. Ingram; Extra, Mr. Wheeler, gardener to Sir F. Goldsmidt, Bart., and Messrs. F. & A. Smith.

AZALEAS were not so closely trained in as last year, when they had too much the appearance of monster crinolines, and the flowers being relieved by a little foliage, and not too much, the effect was altogether more pleasing. Mr. Veitch's magnificent plants put all other competitors in the shade in the class for eight. They were from 6 to 7 feet high, some were 7 feet in diameter at the base, and the whole were profusely set with bloom. The kinds were *Gledstanesi*, *Cri-*

*terion*, *Rosea superba*, *Trotteriana*, *Chelsoni*, very fine, *Variiegata*, Mrs. Fry, and *Extrani*. In the class for six Mr. Turner was first with plants which, though not on the whole so large as those of Mr. Veitch, were nevertheless extraordinary specimens of cultivation. They were *Barclayana*, *Coronata*, *Arborea purpurea*, *Gem*, *Illustris Nova*, and *Juliana*. Good collections were also shown by Mr. Fraser, Messrs. Lane, and others. Among the new kinds those which were finest were *Louise von Baden*, large pure white and apparently free-flowering, *President*, rosy salmon, large, and very fine in form and substance, *Kinghorni*, rosy lilac, also of fine form and great substance, and *Mars*, orange red. The above were shown by Mr. Turner.

Prizes.—For eight (nurserymen): first, Mr. Veitch; second, Mr. Fraser; third, Mr. Rhodes. For eight (Amateurs): first, Mr. Carson; second, Mr. J. Wheeler; third, Mr. Page; fourth, Mr. Whitebread. For six (nurserymen): first, Mr. Turner; second, Mr. Veitch; third, Messrs. Lane; fourth, Mr. Fraser and Mr. Williams. For six (amateurs): first, Mr. Penny; second, Mr. Todman; third, Mr. A. Ingram; fourth, Mr. Kaile; fifth, Mr. Chilman. Prizes were also awarded to Mr. Turner for his new *Azaleas*, and to Messrs. Lane for their collection.

ROSES were shown in splendid condition, especially Messrs. Lane's and Mr. W. Paul's, those from the former were very full of bloom and the flowers distributed all round the plant. *Madame Villermoz*, *Paul Perras*, and *Souvenir d'un Ami* were very fine, and among the others we remarked *Niphetois*, *Chénéolé*, *Victor Verdier*, and *Charles Lawson*. In Mr. W. Paul's collection, *Souvenir d'un Ami*, *Madame Villermoz*, and *Senateur Vaisse* were also remarkably fine. Good collections also came from Messrs. Paul & Son and Mr. Turner, those of the latter being in eight-inch pots. Among them was a plant of *Alba rosea* with beautiful white blooms 5 inches across; and *President*, likewise fine. Numerous boxes of cut blooms were shown by Mr. W. Paul, Messrs. Paul & Son, and Messrs. Lane.

Prizes.—For ten: first, Messrs. Lane; second, Mr. W. Paul; third, Messrs. Paul & Son; fourth, Mr. Francis. For six: first, Mr. Terry.

PELARGONIUMS from Mr. Bailey of Shardeloes threw all others, fine though these were, into the shade. They were marvellous examples of what can be effected by skilful cultivation, being from 4 to 5 feet across, and a mass of bloom. The judges considered that the first prize was not a sufficient reward for such superior cultivation, and gave a medium gold medal of the value of £10. The finest were *Spotted Gem*, *Lord Clyde*, *Sanspareil*, *Etna*, and *Lady Canning*, the others being *Guillaume Severyns*, *Rose Celeste*, *Ariel*, *The Belle*, and *Sir Colin Campbell*. In the nurserymen's class for twelve Mr. Turner had finely-bloomed plants of *Lady Canning*, *Guillaume Severyns*, *Fairest of the Fair*, *Desdemona*, *Lord Clyde*, *Prince of Prussia*, *Garibaldi*, *Rembrandt*, *Pizarro*, *Fair Rosamond*, and *Butterfly*. In Fancies he was first with *Lady Craven*, *Ellen Beck*, *Undine*, *Modestum*, *Delicatum*, and *Roi des Fantaisies*. Very good plants also came from Messrs. Fraser, Bailey, and Wiggins. Some seedlings were also shown, the best of which were *Charles Turner*, from Mr. Hoyle, noticed last week, *Lady of Quality*, also from the same raiser, a crimson with a white eye and dark top; *Elegans*, from Mr. Nye, a pretty crimson with a conspicuous white eye; and *Clytie*, a light pink and rose *Fancy* from Mr. Turner, to all of which first-class certificates were awarded.

Prizes.—For twelve: first, Mr. Turner; second, Mr. Fraser. For ten: first, Mr. Bailey; second, Mr. Wiggins. For six, Fancies (nurserymen): first, Mr. Turner; second, Mr. Fraser. For four (amateurs): first, Mr. Bailey; second, Mr. Weir.

NEW PLANTS, &c.—Among the novelties from Mr. Veitch were *Maranta Veitchii*, with beautifully marked foliage, *Bertolonia pubescens*, also with very ornamental foliage, *Dieffenbachia grandis*, the leafstalks marked with dark green, *Retinospora obtusa nana aurea* and *Anthurium cordifolium*, which have been noticed on previous occasions, and *Peperomia maculosa*, for all of which first-class certificates were awarded; and second-class ones for the following—viz., *Peperomia acuminata*, the leaves deep green with a silvery stripe up the middle, a new Peruvian *Adiantum*, *Schizmatoglottis* sp., and *Odontoglossum cordatum*, which have been

noticed in previous reports. Among other plants from the same firm were *Leptopteris superba*, one of the most beautiful of Ferns, with dense translucent and extremely graceful fronds, a fine pan of *Anthurium Scherzerianum*, remarkable for its curiously-formed spathe and spadix and brilliant colour, and *Dieffenbachia Barquiniana*, having the foot-stalks and midribs of the leaves ivory white. Messrs. Ivery again exhibited the new Ferns, shown at the Crystal Palace. First-class certificates were given to all but *Scolopendrium fissum-latum*, which had a second-class, a similar award being made for *Asplenium adiantum-nigrum microdon*. Mr. Bull likewise exhibited new plants, a most extensive collection, but most of them have been seen before at Floral Committee meetings from time to time. First-class certificates were given for *Ficus Porteana*, the variegated *Aubrieta purpurea*, *Sphærogyné cinnamomea*, the beautiful *Bertolonia margaritacea*, *Athyrium f. f. Vernoniae*, *Retinospora leptoclada*, the new red-bracted *Bougainvillæa*, *Cupania undulata*, *Asplenium myriophyllum*, *Maranta Van den Hecke*, and *Calonyction sanguineum*, for several of the new *Aucubas*, and for *Woodsia polystichoides Veitchii*. Besides these he sent several plants, such as *Amorphophallus zebinus*, the variegated *Sedum azoides* and *Privet*, &c. Messrs. Jackson, of Kingston, exhibited *Columnæa erythropha* with scarlet flowers 3 inches long, and a variety of *Clerodendron Thomsonsæ* with larger flowers; and Mr. Thompson, Ipswich, *Aquilegia cœrulea*, all of which had certificates of the first class.

Among miscellaneous objects were a group of hardy Ferns from Messrs. Ivery, Palms from Mr. Bull, *Calceolarias* of a good strain both in large and small pots from Mr. James of Isleworth, Pansies, and a wreath of *Bougainvillæa* from Mr. Fleming of Cliveden, covered with its beautiful rosy bracts, the peculiarity of which was that it had been grown without bottom heat. The Castle Kennedy Fig was exhibited by Mr. Fowler, the gardener at that place; two dishes of Strawberries by Mr. Carmichael, gardener to H.R.H. the Prince of Wales at Sandringham; and a basket of excellent *Granadillas* by Messrs. Mart, of Oxford Street.

The American plants of Mr. John Waterer added an additional attraction to the Show, and in a few days the *Rhododendron* valley will present a gorgeous spectacle. As it was, it constituted a show of itself, and one of no small merit.

## ROYAL HORTICULTURAL SOCIETY.

### FLORAL DECORATION FÊTE, MAY 24.

THE array of titled dames and other notabilities, the fact of its being the Queen's birthday, and the amount of prizes offered, were all insufficient to produce anything but a most wretched display; and sorely did I grudge the two hours that it took me to reach Kensington from the Regent's Park, make my notes, and return. My own inclination would lead me to say nothing about it, for folks will hardly credit what a miserable failure it was. The Show, if such it can be called, was held in a corner of one arcade, which was more than enough to receive all the subjects for competition. There were decorations for churches, a few bouquets, a few wreaths, and some flower-stands for tables of artificial and natural flowers. With regard to the first of these, I must own I do not see why the Royal Horticultural Society is to assume that all its members approve of the system of church decorations. There are many persons who think that this wants checking rather than encouraging, and it seems to be not quite correct to throw the influence of a large Society into one side of the question. However, let that pass, for I do not think the decorations exhibited would be likely to induce any one to wander in that direction. There was a motto, "Alleluia! The Lord is risen! Alleluia!" formed of yellow Everlastings on a brown ground, which obtained the first prize for Miss Sutherland; a cross with Lilies of the Valley, and a motto entwined round it; then there was another cross formed of *Narcissus* with green background. A third prize was awarded to a double triangle, an ornament intended for Trinity Sunday; one was decorated with *Cornflowers*, the second with red *Pelargoniums*. Such were the church decorations. Then Mr. Lucking exhibited some pretty bouquets, nearly equal to what one may see in Covent Garden any day. They were, of course, pretty; and the

bridal one, formed mainly of Orange flowers, double *Pri-mulas*, Lilies of the Valley interspersed with Maiden-hair, was doubly good. There were two or three wreaths with the motto, "God Save the Queen," the taste of which was not, I hope, a test of the loyalty of the makers, for they were very confused and ugly. A group of rice-paper flowers arranged in one of Miss March's stands for the dinner-table, exhibited by Miss Austin, Hector Villa, Wilnot Road, Dalston, was very pretty indeed, but did not come within the terms of the Exhibition. There was another stand of a similar character formed of natural flowers, but not by any means remarkable. There was also a contrivance for lighting a dining-room, of which I can only say it reminded me forcibly of the system of lighting which I remember when a boy some of us adopted in a magnificent display of private theatricals, which we held in the coach-loft to the admiring gaze of a dozen of our schoolfellows. We cannot find fault with the Society for endeavouring to create a better taste in these matters; but I think all will feel that after the failures of last year and this, it will be better to try some other plan of "evolving it out of the depth of our æsthetic consciousness."—D., Deal.

MESSESS. WATERER & GODFREY'S AMERICAN SHOW is now in full perfection, and the immense tent in which it is held, covering an area of 350 feet long by 150 feet wide, and containing several hundreds of *Rhododendrons* and *Azaleas*, presents a glorious spectacle, for though many of the plants suffered considerably from the severe frost of the 30th of April, they are nevertheless in excellent bloom. In the centre, which is sunk considerably below the sides, is a gravelled walk at least 30 feet wide, with several circular and oblong beds containing specimen plants, and on each side of this central walk are banks of *Rhododendrons* edged with turf; then walks, 8 feet wide and other beds on a higher level, and finally a walk surrounding and overlooking the whole, with Conifers intermixed with *Rhododendrons* next the walls of the tent. The following are the best of the different colours:—Purple: *Nero*, *Curiceanum*, *Ne Plus Ultra*, and *Sir Isaac Newton*. Crimson: *Atrosanguineum*, *Blandyanum*, *Brayanum*, *Mrs. W. Bovill*, *Archimedes*, *Charles Bayley*, and *Vandyke*. Rose: *Sir Charles Napier*, *Roseum pictum*, *Elfrida*, *Giganteum*, *Titian*. Crimson-edged: *Alarm*, *Bylsianum*, and *Concessum*. Lilac: *Everestianum* and *Fastuosum flore pleno*. White: *Mrs. John Clutton*, very fine and of beautiful form; and *Purity*, which, though not equal to the former, is cheaper. Of new kinds, *Stella* is a pale rose with a dark blotch in the upper petal, and a great improvement on *Lady Eleanor Cathcart*, having larger flowers; *Lady Clermont* is a fine salmon with dark spots; and *Charles Dickens* and *H. H. Hunnewell* are beautiful additions to the bright crimson class, the latter in particular having a very large truss. *Alexander Dancer*, with large rosy crimson flowers with a slight magenta tinge, is also a fine variety.

## FLOWER SHOW AT THE CRYSTAL PALACE.

### FLORISTS' FLOWERS.

THE excision of cut flowers from the schedule, a step taken in order to enable the Company to throw more weight into the more showy and important classes, had the effect of considerably diminishing the number of florists' flowers at the Great Show; for with the exception of a box of *Roses*, two of *Pansies* and *Tulips*, respectively from Messrs. Paul and Son, Downie, Laird, & Laing, and Mr. Ayres and Mr. Turner, there were none to be seen in a cut state. The value of the two former collections, beautiful as they were, was considerably diminished by their not having any names attached. I have never seen cleaner or more beautiful *Tulips* than were in the stand of Mr. Turner, their shape, texture, and size being all that could be desired. The *Pansies* were also exceedingly clean and well grown; but there was nothing very striking amongst the *Roses*, a few blooms of *Teas* being, however, as they always are, pleasing.

In *Pelargoniums* in eight-inch pots the two principal exhibitors were Mr. Fraser, of Lee Bridge, and Mr. Charles Turner, of Slough, who were placed first and second. Those sent in by amateurs were very inferior; so much so that in

one class the second and third prizes, and in another the first and second, were withheld from want of merit. Mr. Fraser's twelve Pelargoniums in eight-inch pots comprised *Rose Celestial*, *Etna*, *Fairest of the Fair*, *Leviathan*, *Sylph*, *Roseum*, *Lurline*, *Osiris*, *Sir Colin Campbell*, *Lilacina*. Mr. Turner's contained *Lilacina*, *Lady Canning*, *Leviathan*, *Desdemona*, *Fairest of the Fair*, *Candidate*, *Guillaume Severyns*, *Rose Celestial*, *Bertie*, *Ariel*, *Royal Albert*, and *Celeste*. These were all fine specimens of cultivation, but there was a freshness about Mr. Fraser's which placed him in the position that he occupied. In Fancies the run was very close; and although Mr. Fraser's did win, it was only by a neck, the overbloomed state of *Roi des Fantaisies* in Mr. Turner's lot being the point, I fancy, that told against him. I wonder that this variety is grown for exhibition, for notwithstanding the brilliancy of its colours, it is so flimsy that it can never be depended upon, and is so soon shattered by a journey. Mr. Fraser's six were *Queen of the Valley*, *Roi des Fantaisies*, *Delicatum*, *Celestial*, *Arabella*, *Goddard*, and *Cloth of Silver*. Mr. Turner's were *Lady Craven*, *Evening Star*, *Roi des Fantaisies*, *Celestial*, *Ellen Beck*, and *Delicatum*. Both collections were models of fine growth, and it would be difficult to imagine how they could be surpassed. Of seedling Pelargoniums there were not many exhibited, but one or two were of great excellence. Charles Turner (Hoyle), is a fine, beautifully shaped, orange scarlet flower, and must in the eye of the raiser be considered first-rate, or he would never have named it after Mr. Turner. It was awarded a first-class certificate, as was *Marion*, a large soft rose with clear white throat. *Elegans*, a fine, clear, painted flower, received a second-class certificate.

Roses in pots were exhibited in fine condition, and deservedly attracted great attention. The first prize for twelve in 13-inch pots was awarded to a very fine collection from Mr. Wm. Paul, containing *Souvenir d'Elise Vardon*, very fine; *Louise Odier*, good; *Baronne Prevost*, poor; *Madame Villermoz*, very fine; *Souvenir d'un Ami*, a splendid plant; *Senateur Vaisse*, good; *Paul Perras*, *Comtesse de Barban-tanne*, *Madame de St. Joseph*, very fine; and *Catherine Guillot*, beautiful. Messrs. Paul & Son and Messrs. Lane were placed equal second, one collection being not quite out, and the other a little overblown. The former contained *Madame Julie Daran*, excellent; *Jules Margottin*, *Comte Boubart*, *Niphotos*, *Charles Lawson*, excellent; *Paul Ricaut*, *Coupe d'Hébé*, *Souvenir d'un Ami*, and *Madame de St. Joseph*, very fine. Messrs. Lane's were—*Catherine Guillot*, *Souvenir d'un Ami*, *Anna de Diesbach*, *Coupe d'Hébé*, *Victor Verdier*, *Gloire de Dijon*, *Charles Lawson*, *Moiret*, *Paul Perras*, and *Souvenir de la Reine de l'Angleterre*. The collections of twelve Roses in eight-inch pots were greatly admired, and deservedly so, for they were admirably grown, and are of a size more pleasing to the general run of fanciers than the larger plants. Mr. Turner was placed first with a beautiful set, in good condition, clean and fresh. They were *Madame Villermoz*, *Catherine Guillot*, *Senateur Vaisse*, *Celine Forrestier*, *Victor Verdier*, *Charles Lawson*, *Le Rhone*, a splendid flower, *Gloire de Dijon*, *Souvenir d'un Ami*, *Baronne Adolphe de Rothschild*, and *Juno*. Messrs. Paul & Son were second, and had *Maréchal Vaillant*, good, *John Hopper*, *Victor Verdier*, *Madame Rivers*, *Senateur Vaisse*, *Charles Lawson*, *President*, *Catherine Guillot*, &c.

A more successful exhibition was never held at the Crystal Palace, and, as usual, the greatest courtesy and attention was shown to all engaged in it. The crowds of people that thronged the parts where the Roses, Geraniums, &c., were staged showed how popular these flowers are; and one could not help feeling how well deserved were the encomiums which were passed, not only on the plants, but upon the Company, who so liberally and promptly fell into the wishes of the exhibitors, and on Mr. Wilkinson, who with so much urbanity and attention carried out the arrangements for the Show.—D., Deal.

#### MR. SALTER'S PYRETHRUMS.

VERSAILLES NURSERY, HAMMERSMITH.

No time should be lost by all admirers of hardy herbaceous plants, in visiting Mr. Salter's garden. The magnificent collection of both single and double Pyrethrums

is now in perfection. It would be difficult to do justice to their beauty by any attempt at description, they must be seen to be appreciated, and no one will feel disappointed who will take the trouble to inspect them. The vivid colours of rosy red and carmine are very attractive, both in the single and double varieties. As a decorative border plant, we have nothing at this time of the year to equal them; used as border plants in front of a shrubbery they will be very effective. In a short time the herbaceous Pæonies will be in perfection. These exquisite hardy plants are but little known, or they would be highly appreciated. Those who are beginning to tire (if not already weary) of beds of yellow and scarlet, would do well to inspect Mr. Salter's general and extensive collection of hardy herbaceous plants. The collection of Zonale Pelargoniums in this establishment is very first rate. There are several seedlings of 1864, which will take a prominent position in this deservedly popular class of flowers; but if for no other purpose let no lover of useful decorative hardy plants lose any time in paying his or her respects to the Pyrethrums.—X.

#### THE BEARING-POINTS OF PEACH AND NECTARINE TREES.

It is generally supposed that when standard Peach and Nectarine trees are planted in the border under glass the fruit will be borne chiefly by that part of the tree nearest to the glass, but after many years' experience I have proved the reverse to be rather the case. I have eight of these trees planted out, and I think there is even more fruit where the branches commence from the stock than in any other part of the tree, and all the trees are loaded with fruit, with the exception of two, which I had ordered to be dug up, as they are of a sort which does not answer under glass. For the same reason the shoots grow out immediately above the stock where the graft is, so that the trees can always be kept in shape. Some of these stocks are now 10 inches round, and I have one Nectarine of which the branches extend 10 feet in diameter. It is quite loaded with fruit, some of which last year sold in Covent Garden at 18s. the dozen.—CONSTANT READER.

#### REPORT ON THE BEDDING PELARGONIUMS GROWN AT CHISWICK, 1864.

BY THOMAS MOORE, F.L.S., SECRETARY TO THE FLORAL COMMITTEE.

THE most approved sorts are indicated throughout by three asterisks (\*\*\*) and the next grade by two (\*\*). The varieties which are not distinguished by any mark are to be regarded either as unnecessary, from their similarity or inferiority to other kinds, or from their absolute worthlessness.

##### SERIES I.—PLAIN-LEAVED VARIETIES.

##### 1. FLOWERS SCARLET.

*Achilles* \*\* (Presented by Mr. Bull).—Vigorous habit; flowers large and of fine shape, in fair-sized trusses, scarlet, lighter and brighter than *Punch*. This was formerly called *Vivid*, but the name has been since altered to avoid confusion, there being already a fine scarlet variety bearing this latter name.

*Brilliancy* (Bull).—Vigorous habit; flowers in immense trusses, large, and of a bright scarlet, but not distinct enough from *Punch*.

*Doris* (Bull).—Vigorous habit; flowers large, light scarlet. Too thin as a pot plant.

*Eleanor* \*\*\* (Bull).—Dwarf, free habit; flowers large, scarlet, of good quality. As a pot-plant, under glass it proved also dwarfish and free, with bright scarlet flowers in large trusses, for which it was adjudged three marks.

*Envoy* (Bull).—Vigorous habit; large scarlet flowers in large trusses, but not considered superior to *Punch*.

*Faust* \*\*\* (Bull).—Vigorous habit; flowers very bright scarlet, large, and of first-rate shape, borne in large trusses. It proved also a very showy plant when grown under glass, producing immense heads of flower.

*Garibaldi* (Downie & Co.).—Vigorous habit; flowers scarlet, of good quality; much in the style of *Punch*, and too much like it to be also required.

*Harkaway* (Taylor).—Dwarf habit; leaves smooth; flowers orange scarlet, of loose shape.

*Lady Cowper* (Francis).—Dwarf and compact; flowers light scarlet, white in the eye. Too near to Waltham Pet.

*Lady Rokeby*\*\*\* (Bull).—Moderately vigorous habit; flowers light scarlet, in fair trusses. This proved good as a pot plant, but not so good as a bedder.

*Le Zouave* (Van Houtte).—Vigorous habit; flowers large, very bright scarlet, but not sufficiently numerous in the truss.

*Little David*. (Low & Co.).—Very similar to Little Major, and, like it, suitable for small beds, or for edgings.

*Little Major*\*\*\* (Turner).—Dwarf habit; flowers light scarlet. This variety maintained its previous character as a good dwarf bedder.

*Major Domo* (Bull).—Moderately vigorous; flowers light scarlet. A fine bold plant for pot culture.

*Mars* (Turner).—Dwarf, moderately vigorous habit; leaves distinctly lobed; flowers of good form, very bright orange scarlet.

*Palastro* (Salter).—Dwarfish habit; leaves lobed; flowers dull orange scarlet.

*Punch*\*\*\* (Fraser, Turner).—Vigorous habit; flowers large in bold ample trusses, bright scarlet, and very showy. The best of the large-growing plain-leaved scarlets in the whole collection.

*Red Dragon* (W. Paul).—Vigorous habit; leaves faintly green-zoned; flowers very rich deep scarlet in compact trusses, and of good form. The deepest coloured scarlet in the whole collection.

*Rigby's Queen* (Fraser).—Vigorous habit; leaves hairy; flowers large, loose, light scarlet. Not adapted for beds.

*Royal Dwarf* (Turner).—Moderately dwarf habit; flowers scarlet, free, but not equal to Trentham Scarlet.

*Royalty* (Bull).—Vigorous habit; bright scarlet flowers.

*Royalty* (Williams).—Moderately vigorous; flowers bright scarlet.

*Stella* (Dixon).—Dwarf habit; flowers of a deep rich scarlet, as in Red Dragon, but not effective.

*Trentham Scarlet*\*\*\* (Fraser).—Moderately dwarf; flowers bright scarlet, in good trusses, free. One of the best of the dwarf-growing scarlets for bedding purposes.

*Waltham Pet*\*\*\* (W. Paul).—Very dwarf compact habit; flowers light scarlet, of good shape, with a small white eye. A good dwarf bedder.

## 2. FLOWERS CERISE OR ROSY SCARLET.

*Beauté de Meldeise* (Fraser).—Very similar to Lady Middleton, and too near to be required.

*Lady Middleton*\*\*\* (Taylor).—Moderately vigorous; flowers in large trusses, of good size and form, bright cerise. Also called Trentham Rose and Shrubland Rose.

*Lord John Russell* (Rollisson).—Dwarf habit; flowers deep rosy scarlet; distinct in colour.

*Viceroy* (Bull).—Vigorous habit; flowers large, rosy scarlet.

*Visitor*\*\* (Bull).—Moderately vigorous; flowers rosy scarlet, of fine shape and of large size. It was of indifferent quality as grown in pots.

## 3. FLOWERS ROSE PINK.

*Christine*\*\*\* (Kinghorn).—Moderately vigorous habit; flowers rose pink, freely produced, and of good form. Both this and Rose Queen hold their place in the first rank of bedding varieties.

*Primer* (Bull).—Moderately vigorous habit; flowers bright rosy pink with white base.

*Roseum Compactum* (Salter).—Moderately vigorous habit; flowers in compact trusses, small, rose throughout.

*Rose Queen*\*\*\* (Kinghorn).—Moderately vigorous habit; flowers rose pink, with the base of the upper petals paler, freely produced, and of good form.

## SERIES II.—ZONATE VARIETIES.

### 1. FLOWERS SCARLET.

*Admiration* (Williams).—Moderately vigorous; leaves dark zoned; flowers bright scarlet.

*Adonis*\*\*\* (Hally).—Dwarf, free bold habit; leaves with a dark submarginal zone; flowers large, well formed, in fair trusses, light scarlet, with a white eye.

*Agatha* (Rollisson).—Moderately vigorous habit; leaves

dark zoned; flowers small, well formed, light scarlet, in abundant compact trusses; free and showy.

*Amiral Protet*\*\*\* (Van Houtte).—Moderately vigorous in habit; leaves with an indistinct zone; flowers large, deep scarlet, of fine shape, and produced in bold effective trusses. It proved a very showy pot plant, under which circumstances only it was grown, and it is to this condition that the marks of merit are intended to apply.

*Attraction*\*\*\* (Turner).—Moderately vigorous; leaves with an indistinct green zone; flowers abundant, bright scarlet, in fine trusses, of good form and moderate size. Also called Scarlet Perfection, Sutton's Perfection, Old Perfection, Boule de Feu, and Montfordi.

*Baron Ricasoli* (E. G. Henderson & Son).—Moderately vigorous habit; leaves with sharply defined dark zone; flowers in fair-sized trusses, dull crimson scarlet.

*Beauty* (Bull).—Moderately vigorous; leaves with broad dark zone; flowers large, scarlet.

*Cheshire Hero*\*\* (Wills).—Moderately vigorous habit; leaves with an indistinct zone; flowers soft, light scarlet, with a cerise tint, free.

*Climax* (Bull).—Moderately vigorous; leaves with an indistinct zone; flowers bright scarlet. Indifferent under glass.

*Clipper*\*\*\* (Bull).—Moderately vigorous habit; leaves with broad dark zone; flowers bright scarlet, large and of fine shape, produced in good trusses. Equally good as a pot plant under glass.

*Comet* (J. F. Chater).—Dwarfish habit; leaves with dark centre or zone; flowers scarlet.

*Commissioner*\*\* (Bull).—Vigorous habit; leaves with broad dull-coloured zone; flowers in compact trusses, well formed, of a bright orange scarlet; a fine variety.

*Cornelius Hegel* (E. G. Henderson & Son).—Dwarf habit; very broadly dark-zoned leaves; flowers light scarlet.

*Cottage Maid*\*\* (Scott).—Vigorous habit; leaves dark zoned; flowers abundant, in compact trusses, light scarlet, small and well formed. A free showy sort; the same as New Globe, or too closely resembling it.

*Editor* (Bull).—Vigorous habit; indistinctly zonate leaves; large bright scarlet flowers.

*Emperor of the French*\*\* (Turner).—Vigorous dwarfish habit; leaves large, very distinctly zoned in a vandyked pattern; flowers large, in bold trusses, light scarlet.

*Etandard* (Salter).—Dwarfish free habit; leaves with an indistinct and unequal broad zone; flowers deep scarlet.

*Firefly* (G. Smith).—Dwarf habit; leaves dark zoned; flowers abundant, bright scarlet.

*Foxhunter* (J. F. Chater).—A small weak plant; leaves marked with a narrow dark zone; flowers scarlet.

*Gaiety* (Hally).—Moderately vigorous habit; leaves darkly zoned; flowers light, bright scarlet, with a pale eye.

*Garibaldi*\*\*\* (W. North).—Very dwarf close habit; leaves small, flat, with a broadish well-defined dark zone near the edge; flowers bright scarlet, of good shape, in compact trusses. A beautiful plant for small beds or margins.

*Harry Hieover*\*\* (E. G. Henderson & Son).—Dwarf habit; darkly-zoned leaves; loose orange scarlet flowers. It was considered rather desirable as a dwarf variety for edging flower-beds.

*Hibberd's Pet* (Carter & Co.).—Of moderately vigorous habit; leaves dark zoned; flowers light scarlet but not effective, the trusses being small and the flowers loose. It was also of indifferent quality under glass.

*Lilliput* (Turner).—Dwarf; leaves darkly zoned; flowers scarlet, in small trusses.

*Lucien Tisserand*\*\* (E. G. Henderson & Son).—Moderately vigorous habit; leaves marked with a dull broad zone; flowers showy, large, bright scarlet with a light eye.

*Lucius* (Bull).—Vigorous habit; dark-zoned leaves; scarlet flowers.

*Martin Gireau*\*\*\* (Rollisson).—Vigorous habit; leaves with broad dull zone; flowers large, in fine trusses, of good form, light scarlet.

*Meteor* (J. F. Chater).—Moderately vigorous; leaves dark zoned; flowers scarlet.

*Neatness* (F. & A. Smith).—Dwarfish vigorous habit; leaves with dark vandyked zone; flowers of good form, large, scarlet, in small trusses.

*Persian*\*\* (Bull).—Vigorous habit; very dark broad zone; flowers fine, large, and well formed, of a soft carmine scarlet.

*Petit Mont Rouge* (E. G. Henderson & Son).—Dwarf habit; leaves with a dark zone; flowers very bright scarlet.

*Philomelle Leseine* (E. G. Henderson & Son).—Leaves marked with a dull zone; flowers light scarlet.

*Princess of Prussia*\*\* (Rev. J. Dix).—Vigorous habit; leaves with an indistinct zone; flowers small, salmony scarlet, in large close trusses. A good pot plant, but not very well developed in this instance.

*Queen Mab* (Hally).—Dwarf habit; leaves dark zoned; flowers orange scarlet.

*Really Good* (Bull).—Vigorous; dark-zoned leaves; flowers light scarlet, of fine shape.

*Red Jacket* (Veitch, Turner).—Vigorous habit; leaves broad with narrow dark vandyked zone; flowers light scarlet. Similar to Emperor of the French, but inferior to it.

*Red Riding Hood*\*\* (Hally).—Dwarf habit; leaves dark zoned; flowers very bright scarlet, of fine form.

*Reidii* (Fraser).—Dwarf vigorous habit; leaves dark zoned; flowers deep scarlet with white eye, in small trusses.

*Rev. Joshua Dix*\*\* (the Society).—Moderately vigorous compact habit; leaves marked with a dull zone; flowers above medium size, of good shape, in compact trusses, and of a very bright scarlet. A seedling raised at Chiswick, and both distinct and good.

*Senator* (Williams).—Vigorous habit; leaves with very dark centre or broad zone; flowers scarlet.

*Victor Emmanuel*\*\*\* (Clarke).—Vigorous habit; leaves with broad dull zone; flowers large, in bold trusses, and of fine quality, very similar to those of Punch. One of the best of the zonate scarlets.

*Vivid*\*\*\* (G. Smith).—Moderately vigorous habit; leaves with broad dull zone; flowers of fine form, in bold trusses, of a bright scarlet. A very fine sort, one of the best as to the shape of the flowers, and equally good as a pot plant.

*Volcano*\*\*\* (Wills).—Moderately vigorous habit; leaves with indistinct green zone; flowers light orange scarlet, large, in bold trusses, and freely developed.—(*Proceedings of the Royal Horticultural Society.*)

(To be continued.)

## THE MODERN PEACH-PRUNER.—No. 10.

### FORMS OF TREES FOR LONG PRUNING.

ON the question of form there is not so much real difference of opinion as exists as to the most advantageous way of managing the shoots. It is true we can find, especially in the French works, a great variety of shapes indicated as suitable according to circumstances, but many of them are too fantastic to be of any practical use. Examining them is not, however, without profit, for we may generally trace in them some leading principle based on reliable ex-

perience. Thus the student will discover that the chief aim and object steadily adhered to, has generally been to divide, as near to the base of the tree as possible, the main current of the ascending sap into two well-balanced portions. Wherever this leading principle has been departed from, it will be seen that the object then in view was to cover a somewhat lofty wall in the quickest manner, without at the same time sacrificing the claims of the lower branches to be

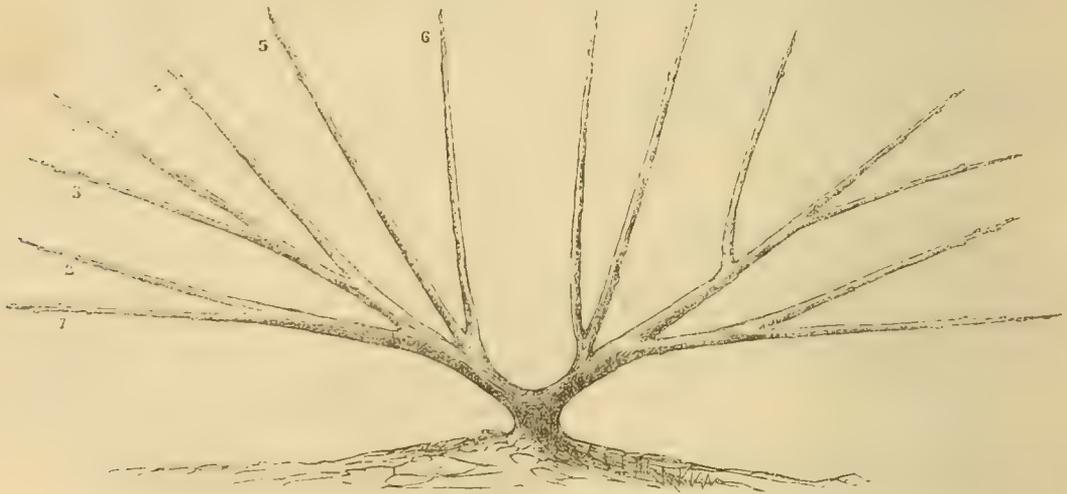

FIG. 9.—The Montreuil Fan.

properly constituted. For this purpose a main central stem has been provided, much less lateral expansion has been allowed, whilst the lowest branches have sometimes been turned upwards at their extremities to favour their development, for that development is always endangered under this form. It is evident that walls of 9 or 10 feet in height, which are by no means the worst suited for many localities, require a shape combining great power of lateral expansion, without sacrificing the harmonious proportions of the whole tree. To accomplish this there is certainly no form which equals the *espalier carré*, of which, as the name indicates, the squareness constitutes the chief advantage.

This form has, therefore, been selected as a model for walls of about 9 or 10 feet in height, where a large tree of any favourite variety was desired. At the same time it cannot be too often repeated that modern gardeners prefer smaller-sized trees and more in number. In this way a succession of crops is best secured, and a greater variety of fruits may be cultivated.

For walls of about 12 feet in height the old Montreuil fan is extremely well adapted. It is a symmetrical shape, easy to establish, and durable. In both of these old and well-known forms it will be seen that the sap has been directed into two main channels from the commencement of the formation of the trees. These channels remain to the last as the main arteries of the whole system. Their position at the most favourable angle, and their early formation cause, as Lepère truly remarks, the sap to acquire "the habit of using them in preference," while their larger proportions secure a more abundant flow. Kept carefully balanced, by the usual means, during the first five or six years, they continue as the guiding principles of either wing. Their importance and use are aptly explained by their French name, "mother branches," and in each of these forms they are marked 1, in our engravings.

The *espalier carré* and Montreuil fan are neither of them difficult to acquire. Their harmonious proportions are far more pleasing, even when without foliage, than the ordinary

irregular fan shapes. It is surprising that these irregular shapes should still be recommended in works on this subject. The reason given is that the vicissitudes of the English climate require irregular forms, as being those most easily remedied when injured. But it would seldom happen that either of the leading branches in the *espalier carré* could be irretrievably injured, while in the case of the Montreuil fan, it would suffice to lower the branch immediately above the injured portion into the blank space, allowing a new shoot to grow from its upper side to fill up its old place. For these and other reasons these two forms are here selected as models for long pruning. Other forms will occur when close pruning is treated of. Those with a main central stem from which lateral branches are developed yearly, are of obvious formation. In them the lowest branches should be carefully established from the first, as these generally languish in the course of time.

THE OLD MONTREUIL FAN.

In the first year the leading branch (marked 1) of either wing is developed, and carefully balanced by the usual means (described in No. 7, Section 2). Both of these leading branches are shortened to about 12 inches at the first winter pruning, and during the course of the second season of growth the secondary branch (marked 2) of either wing is developed. At the winter pruning the leaders (1) are shortened in again, but considerably less (unless bare), while the secondaries (2) are encouraged to extend more freely. During the third season of growth another secondary (marked 3), and a tertiary (marked 7) in either wing, are simultaneously produced. The winter shortening of all these branches is now still less. During the fourth year all these existing branches are simply maintained in equi-

librium, in order to remedy any defects before proceeding further. In the meantime the shoots on all these branches have been carefully stopped, so as to equalise still more the tree, and to make them fruitful. A little fruit has by this time been taken, but not much. Another object is to allow the tree to gather strength, and to habituate the sap to these channels before proceeding to form the upper portions, which, being more vertical, are more liable to become too strong.

In the ensuing, or fifth season, the two secondaries (4 and 5), of either wing are now developed simultaneously. During the sixth year the whole form is maintained in equilibrium, and the tree has now become productive and vigorous, while the branches require much less shortening. In the seventh season, the tertiary (6), of either wing is developed, which completes this beautiful and simple form. After this nothing is needed but to keep the shoots close and healthy. The weak points are at the angles of insertion of the secondaries, where the shoots are more apt to be crowded than in the *espalier carré*; but this is a defect inevitable in any form partaking of this character, as is seen in the case of Seymour's training and other modes.

THE ESPALIER CARRÉ.

The leading branches (marked 1), of either wing are first developed, and treated as in the case of the Montreuil fan. The second year the first lower secondary (marked 2), of either wing is produced. In the third year the second lower secondary (3), and in the fourth year the third lower secondary (4), of either wing are established. The fifth season is devoted to equalising the whole form. In the fifth, sixth, and seventh years the three upper secondaries are developed, and the upright tertiary (8), of either wing

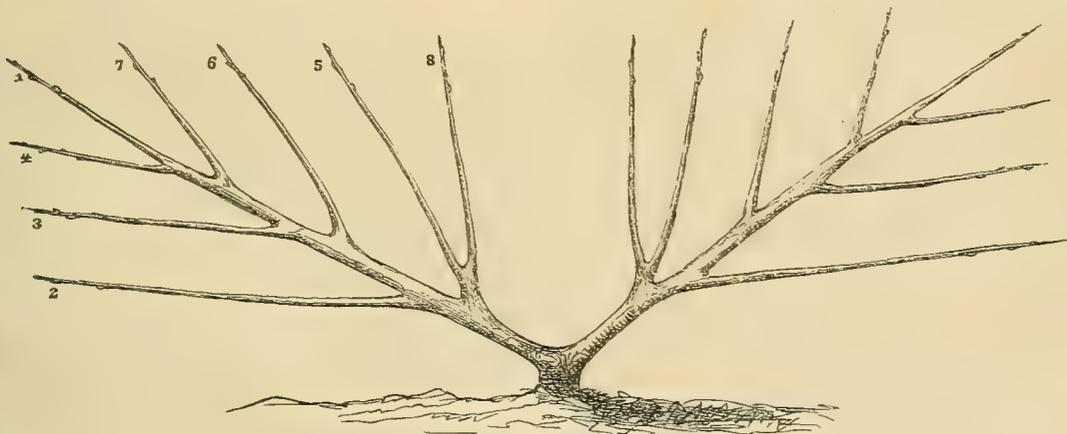

FIG. 10.—The Espalier Carré.

being also laid in, the form is complete. The branches are shortened less at every ensuing winter pruning, and the fruit-shoots carefully stopped from the second year.

The weak points of this fine old form are the rather large interval between the extremities of the secondary branches, amounting to nearly 3 feet. In close pruning, with the shoots more shortened-in, much wall space would be wasted, therefore, the *espalier carré* (unless with a greater number of secondary branches), would not be so suitable. But, on the other hand, the angles made by the insertion of the secondaries on the leading branches are open, and afford much scope for furnishing these difficult portions of the tree. The largest tree at present in the Lepère gardens extends over 40 feet of wall, and one eight years old and just complete, measures 30 feet in width. These are trees of free-growing varieties, such as Grosse Mignonne, &c., and superbly cropped.

Good specimens of waved forms may be seen in England and France. In this case it is proper to divide the tree into two wings, though with a waved central main stem there is little danger of the tree being out of balance. In either of these cases the interval between the branches which are laid in horizontally, should be about 2 feet. In short, excessive

shortening of the branches should be avoided; all vertical lines should be left till the last to be established, and for the first years little fruit should be expected. When once the tree is well formed the branches may be left untouched, and the shoots being carefully attended to, the tree will bear and grow. In irregular fans with central stems, the fruit is comparatively valueless in the lower branches, which languish as the sap is attracted to the upper branches, while the whole centre of the tree is apt to become bare and exposed for the same reason.—T. BRÉHAUT, *Richmond House, Guernsey.*

WIREWORMS.

My garden is infested with wireworms, they have destroyed one row of Peas, and have attacked Scarlet Runners, notwithstanding that I put over the seed a plentiful supply of coal ashes. Last year my Scarlet Runners were nearly destroyed by them, and I barely got my seed back. I have tried various remedies—salt, soot, and lime, but cannot succeed in driving them away. Just to show you what quantities there are, I pulled up a few Turnips that had been dug-in, and had sprouted, and they were eaten into

holes, and the holes were literally swarming with the wireworms.

In a book I have by my side, a paragraph gives a method of extirpating the wireworm—namely, by sowing a crop of White Mustard seed on the field infested by the worm. Will you tell me—First. Whether you think this plan worth trying. Second. The proper time for sowing the Mustard seed. Third. Whether the crop can be made available for any purpose?—WIREWORM.

[Wireworms are so tough-skinned that no amount of salt or lime would kill them, less than a quantity which would destroy vegetation also. Oil is the most fatal of applications to these vermin, and we therefore incline to believe those who state that if seed is covered thickly with Rape dust, which retains some oil, it preserves the seed, and is fatal to any wireworm entering the dust. If Mustard sown in a field extirpates the wireworm, it must be, we think, by being offensive to the beetle (Elatery), to which the wireworm eventually is transformed. Those who advocate the use of White Mustard, drill it on the land, and allow no other crop or weed to grow there. The seed of the Mustard, of course, would be saleable.]

#### DATURA CHLORANTHA CULTURE.

In answer to "PUEB," I shall first observe that this plant has large vine-like foliage, and large, trumpet-shaped, single or double flowers, those of the double variety being in my opinion the better, of a rich yellow colour, and finely scented. It is one of those half-hardy plants that do little good planted out of doors, though a sojourn there for a limited period is of advantage to plants required for late blooming. To do any good planted outside it requires a sheltered border, but though it does very well in some warm situations, yet it has never fallen to my lot to find one warm enough. To produce its flowers satisfactorily, the plant should be placed in heat in spring, vigorous growth induced, well hardened off, and not planted out before the middle of June, and then only in a warm situation.

The seed should be sown in March, in sandy loam and leaf mould, and the pot plunged in a brisk heat of from 70° to 80°. In this it should be continued until the plants are sufficiently large to handle, when they may be potted singly in small pots, and as soon as well established removed to a warm greenhouse or vinery, affording abundance of light by close proximity to the glass, and fresh air, to keep them stiff and short-jointed. If grown in the shade they are spare and dwindling. Pot as the plants fill the pots with roots, using pots a size larger each time until in 9 or 10-inch pots, using at the last potting soil from rotted turves chopped fine two-thirds, and leaf mould one-third, with a free admixture of sharp sand. Keep the plants liberally supplied with water, but never water until the soil appears dry, then give enough, and before the foliage droops. When the trumpets appear liquid manure in a very diluted form may be employed at every alternate watering. Avoid keeping the soil very wet, nor is rich soil good for them whilst young. They are very liable to the attacks of red spider, and should be syringed to keep it in check. Plants raised in spring occasionally bloom well in autumn when grown in a greenhouse. Whilst in bloom they need the same liberal watering as when growing, but after flowering the supply should be diminished, and the plants wintered in a dry part of the greenhouse, giving no more water than enough to prevent the wood shrivelling. I find they flower much finer the second year than the first, and with greater certainty, if well exposed to light and air, and but sparingly supplied with water in the autumn. Thus the wood is ripened, which is an important point. This, of course, can be done very easily by diminishing the supply of water after blooming, even if it be late, and placing near the glass, very little water being given after the leaves fall. They will live in a house from which frost is only just excluded, if the soil is dry, and the wood well ripened; but they are annuals if the soil is kept wet, for the wood not being well ripened it shrivels, and they are almost certain to damp off.

In the spring of the second year the shoots may be cut in to three or four eyes, and the plants shifted into pots of less size, reducing the ball considerably, potting in sandy loam

with a little well-rotted manure, and providing good drainage. If there is convenience to plunge the pots in a mild hotbed that will be of service, and so, too, is bedewing the shoots night and morning. When the shoots are an inch or so in length the plants should be potted into their blooming pots, those of 12 or 15 inches in diameter are not too large. Use rich turfy, sandy loam, a little leaf mould, and sand if necessary. Drain to one-third the depth of the pots, for abundant and frequent watering will be required. They may be grown on in a warm greenhouse or vinery until June, when they may be transferred to a greenhouse or conservatory to bloom, or they may be hardened off, and the pots plunged in a warm situation out of doors, where they sometimes bloom well. I have put a portion outside, taken them up early in autumn, and found them flower finely in the greenhouse late in the season. They were usually taken in early in September. If allowed to bloom outside they should be removed before frosts occur, and be kept dry in a house secure from frost during the winter. Planted out in the borders of a greenhouse they form fine objects.

To obtain a more continuous and early bloom the seed may be sown in June, the plants potted off singly in small pots, transferred to 4½-inch pots in September, and kept in these through the winter, on shelves in a warm greenhouse, with little water. In spring they are successively potted as the pots become filled with roots until in 9 or 12-inch pots, after which, when well grown, they produce their golden trumpets in profusion. These are close upon 9 inches in length. Slight encouragement in spring when breaking, and making sure of the wood being well ripened in autumn, with a dry soil in winter, are the main points of their culture.—G. ABBEY.

#### WORK FOR THE WEEK.

##### KITCHEN GARDEN.

ADVANTAGE should be taken of showery weather to transplant and earth-up all crops that require it; if done when the soil about them is dry, the roots will not receive that benefit from rain which they otherwise would do. In pricking-out or transplanting care should be taken to press the soil close to the roots of the plants, if it is left hollow and loose about them drought will soon stop their growth, or probably cause them to perish. To plant with a trowel is far preferable to planting with a dibber, as, with the latter, the roots are either left in a cavity or are crushed together and rendered nearly useless. The difference between careful and careless planting will soon be perceptible in the plants of the same sowing, if, in the one case the plants are dug up with the greatest care, and are then transplanted and watered, and, in the other, they are pulled up, and deprived of half their roots, and as carelessly planted. *Asparagus*, it is advisable to discontinue cutting from weak beds or those which have been only a year or two in bearing. Keep both old and young beds free from weeds, and thin any other crops that may be growing on them. *Broccoli*, prick-out any that is sufficiently advanced in growth. Sow a full crop of Cape and Grange's Early White. *Cabbage*, where they were planted in the autumn at a foot apart in the rows, every alternate plant to be pulled as required for use. This will give those that remain time and space to attain perfection. *Cardoons*, sow a late full crop. Plant-out the early crop; if they were sown in the seed-beds, choose a rich piece of ground for planting them out. It will not be necessary to plant largely of the first crop, as it will soon run to seed. *Celery*, prick-out some of the most forward into trenches, keep it well watered in dry weather. Continue to prick-out from the seed-beds for late crops. *Cucumbers*, where seed has been sown on ridges to produce Gherkins, thin the plants to three under each hand-glass. Keep up the heat of the principal beds, if fine long fruit is required. *Dwarf Kidney Beans*, earth-up those that have been planted-out, and sow again. *Endive*, make another small sowing. The sowing for the main crop should not be made before the middle of the month. *Lettuce*, make a sowing of two or three sorts, by this means the season of one sowing is prolonged. The Paris Coe is a very good summer Lettuce. *Mushrooms*, the hay with which the productive beds are covered will require renewing occasionally, as it is liable to

get damp and mouldy, which will rot the Mushrooms. *Potatoes*, take the first opportunity of earthing-up all that are sufficiently forward, the others to be hoed between, to loosen the earth and to destroy the weeds. *Turnips*, make a good sowing for early autumn use. Thin-out the advancing crops. *Vegetable Marrow*, plant out this very useful vegetable on a rich piece of ground, where there is plenty of room for it to grow.

## FRUIT GARDEN.

Activity must now be exercised in this department, as the rapid growth of the trees will require constant attention in stopping, removing superfluous shoots, and nailing-in. Peaches may now have their final disbudding. Let every shoot not required be removed with a sharp knife, and the remainder carefully nailed-in. Give the fruit a moderate thinning, but leave more than will eventually be required, as a portion will probably fall off in stoning. Apricots to be thinned with the same discretion. Keep the lateral shoots of Vines closely stopped at the first joint. Strawberry-beds may soon require attention as to watering should the weather become dry. After thoroughly clearing the beds, an effectual soaking should be given, and if a moderate watering from the stable tank can be supplied when the ground has been well saturated with clean water, it will greatly assist in securing large fruit. The beds should be mulched as soon after watering as convenient, in order to prevent evaporation and the fruit from being soiled. Next to slates or tiles clean straw is the best material for this purpose. The mowings of lawns are sometimes used, but this material is objectionable, as it forms an excellent harbour for slugs, soils the fruit, and spoils its flavour.

## FLOWER GARDEN.

The weather during the past week has been all that could be desired for present operations. Verbenas and Petunias when turned out into their summer quarters should have the shoots pegged down, the benefit of little basins round the plants will be readily seen, if the weather become hot and dry. Heliotropes and tender annuals may now be planted out with safety. Attend to staking Carnations and Pinks as they grow, this will greatly improve their appearance when in bloom. All annuals to be thinned out as soon as they are well above ground, for if left to grow too thickly they spoil one another. The early-flowering bulbs, as Tulips, Hyacinths, Turban Ranunculuses, &c., should not be left in the ground after the decay of the foliage, as if wet weather occurs they will be making fresh roots, which weakens them for next season. The Pæonies, Phloxes, Delphiniums, Lysimachias, and other tall herbaceous plants must be properly staked.

## GREENHOUSE AND CONSERVATORY.

The early-forced Camellias now showing bud may shortly be placed out of doors. A shady border is frequently resorted to. We would, however, place them facing the sun, and provide a light canvass screen to throw over them. All young or other stock growing on for specimens of high cultivation must now have much room. Let it be a rule that no two specimens touch. Weed out all rough, exhausted, or inferior plants. Very young stock of Ericas, Epacrises, and small fancy New Holland plants will be best in a pit or frame, placing the lights to the north. Pinch off the decaying blossoms of hybrid Rhododendrons, give liquid manure, and, if wanted for early work, endeavour to force them slightly into wood. Get some young Thunbergias put into their final pots for trellising. Look to the runners of the tree Violet, and also the Neapolitan, and do not delay any longer with the Chrysanthemums. Attend to plants for autumn and early winter decoration, such as Japan Lilies, scarlet Salvias, tree Carnations, and things of that sort. Give plenty of pot room, good rich compost, a moist atmosphere, and plenty of space for the proper development of the branches and leaves. The atmosphere of plant-houses can scarcely be kept too moist at this season, therefore, sprinkle every available surface frequently, and syringe growing stock lightly twice a-day during bright weather. Go over twiners frequently, and regulate their growth before the shoots become entangled, but avoid keeping them tied too closely, for they are never seen to advantage unless they are allowed to hang in a natural and graceful manner.

## PITS AND FRAMES.

Young stock in pits and frames will soon be making rapid

growth, and must be carefully attended to as to watering, stopping, training, &c. Examine Heaths frequently for mildew, and apply sulphur the moment it is perceived, some of the soft-leaved varieties being very liable to be attacked by that pest at this season. Expose Zinnias and other tender annuals entirely, night and day, by removing the lights. Plants that are kept to succeed Tulips, Ranunculuses, &c., should have plenty of room given them. Attend to the late-struck plants, they will come in very useful by-and-by to fill up vacancies in beds, &c. Double Wallflowers, Mule Pinks, and some common Dianthus, Alyssums, Phloxes, perennial Iberises, and many kinds of dwarf Cistus, and Helianthemum, may be propagated under hand-glasses in a shaded situation, and will be found very useful next spring.—W. KEANE.

## DOINGS OF THE LAST WEEK.

## KITCHEN GARDEN.

DELIGHTFUL rains on Tuesday evening which have refreshed everything wonderfully, and made not only hoeing, but thinning Onions, Carrots, Parsnips, &c., a work of pleasure, as well as one of utility. The thinnings of Onions dibbled thickly in poor sandy soil, or what is made so by placing a little of such soil on a hard bottom, is a good plan of producing pickling Onions on strong heavy lands. We can hardly grow picklers here by any other mode.

*Peas*.—Have had a nice supply of Tom Thumb Peas from our orchard-house, and also from an early kind we received from an old gardener under the name of Sebastopol, but which, from its appearance, we judge to be Dillistone's Early, of which, however, we shall be more sure ere long. This was planted in front of the lean-to house, and allowed to scramble as it liked to a row of Strawberries in pots. From the same sort we have also gathered on the 22nd out of doors from plants that were turned out from turves. As yet we have gathered none out of doors from Sangster's No. 1 treated in the same way. We suspect that from Sangster's we shall gather double or treble the quantity we shall do from this Sebastopol, or Dillistone's, but then the earliness is a consideration. We know what it is to have ladies and gentlemen going round and counting the pods on Peas and Beans until there should be enough for a dish. We have not yet had a dish of Broad Beans, but shall not be long in having them, and to help the rapid swelling of the Beans inside the pod have watered a row well with manure water, after stirring the soil on both sides of it. There are some old-fashioned epicures who would place little value on the finest specimens of the artistic cook's achievements when compared with a fine dish of young green Broad Beans. Like many other things, they are often spoiled by the attempts made to disguise altogether that they are garden Beans. We are glad that Peas will now be coming in, as the Asparagus must not be cut much more. We are now allowing all to grow freely, otherwise it would be of little use forcing it. *Cabbages*, especially those tied, are now hearting freely, and when we taste one we cannot help wishing that the great bulk of working men should know the luxury that a Cabbage is when cut, boiled, and then eaten, as there is no comparison between such a Cabbage and one that has been lying hours on a stall, after, perhaps, being packed and heated with kindred hundreds in a waggon. For the same reason all market Peas are generally merely so many make-shifts and make-believes. Gentlemen can only have them first-rate when sent from a distance from their own gardens, when they are sent in thin layers, so that they are neither heated nor dried by the air. Gave up planting in the flower garden to sow more Peas, and to stake the secondary and tertiary crops, which want it badly. We have had fine crops of Peas on the ground without staking, but they take up much more room, and the plants are apt to be injured when gathering the pods. The same objection does not apply to

*Scarlet Runners* when grown without stakes. If the plants are topped when a foot high, the pods will come in great bunches near home, and the only extra care they require is covering the ground with grass or clean litter, or such as will be made clean by a good shower, so that the pods may be gathered clean. Where some 3 feet or so in width can

be spared in a cottager's garden, we know of nothing from which such a supply of valuable nourishing food can be obtained, as from a row of Scarlet Runners, without stakes, but topped, and the mass of scarlet flowers and beans close to the ground. It is to us enough, in most places, to sow these Beans in the beginning of May, but the cottager will act wisely if he sow in light rich soil thickly in April, so that he can cover them or protect them at night, and then plant them out 2 or 3 inches apart in the middle or towards the end of May. When grown on the dwarf system without stakes, a few sheets of paper, an old cloth or two, or a few branches with leaves, will easily ward off the first frosts, and by so doing we have often gathered succulent pods far into November. Of course, we are aware of the fine picturesque effect of such Beans when supported by tall sticks, or held up by strings round the wall of a town garden; but pretty well as much produce may be obtained without the labour and expense of sticks and strings. Strange, that in the northern part of our island so little of this Bean is used by the common working people for supplying varied and wholesome nourishment. Such a subject is well worthy the attention of the large-hearted gardeners who have lived in the south, as the brothers Thomson, of Dalkeith and Archerfield. Would that some could thus be instrumental in increasing the comforts of a thinking, intellectual people. On our last visit to Scotland, we had many evidences that this valuable vegetable was used too much as it was in our boyish days—trained against the windows or the wall as an ornament, not as something valuable to be put "intilt" the pot and kettle.

FRUIT GARDEN.

Besides watering Strawberries out of doors, keeping up a good supply under glass, moving a lot under glass that were potted some three weeks ago, thinning Grapes, regulating Melons, thinning and disbudding Peaches in-doors, orchard-house, &c., the chief work has been uncovering all Apricots, Peaches, &c., out of doors—that is, removing the last of the sprays with which they were protected, washing well to take away all collected dust and filth of any kind. Examined Cherries to see if there were any green fly, or rather black fly, and where there was the appearance of anything, dipping the point of the shoot into quassia and soap water, as a very cleanly and effective operation. The only thing that as yet seems to trouble us are some caterpillars, that roll themselves up in the leaf, and others that riddle the leaf as if permeated by myriads of small shot. However, as yet, they are within bounds, and have done but little harm.

ORNAMENTAL DEPARTMENT.

Here much time has been taken up with potting greenhouse and stove plants, giving extra water in these warm days, when the thermometer even at night rivalled the heat of a hot August, instead of the month of May; rolling and mowing lawn; fresh surfacing and rolling walks; moving some herbaceous plants, &c.; but the chief labour has been preparing, hardening-off, and making the ground all right for turning out lots of bedding plants. Those who thought proper to read some late remarks, would perceive that in the preparation of the plants, and that of the soil, are to be found two elements of success. We knew of some hundreds of Scarlet Geraniums taken last year from a shaded vinery, and at once planted out, but it was the middle of September before they recovered from the sudden check. A ten-days hardening-off would have saved all the annoyance. It sometimes happens that to finish a group, plants must be used not so well hardened off as we would wish, but in such a case a few branches, or something of that kind, is placed around them until they become used to the situation. A dull, shady day should be chosen for removing entirely all such protective shading. We have just planted our main straight ribbon borders, which rise from a walk between them. The planting is with smaller things this season, but which will fill the border, and be, we hope, of a regular gradation as to height. From the walk and the grass verge the planting is as follows in straight lines—*Cerastium tomentosum*, *Lobelia Paxtoniana*, *Cloth of Gold Geranium*, *Purple King Verbena*, *Centaurea candidissima*, *Brilliant Geranium*, *Aurea floribunda Calceolaria*, *Stella Geranium*, and *Ageratum*.

We do not intend that any of these shall need much pegging or training to keep them uniform in slope and full, yet distinct, in line so as to prevent stiffness.—R. F.

COVENT GARDEN MARKET.—MAY 27.

Abundant supplies of Cabbages and other Greens continue to pour in. Very good spring Cauliflowers are now to be had, and are taking the place of Broccoli, now nearly over. Of Peas there is an unusual quantity for the season, and they sell at from 4s. to 8s. per bushel; and of Kidney Beans there is also a fair supply. Lettuce and other salading is in great request. Grapes are sufficient for the demand, and very good. Foreign Cherries, consisting of Early Purple Gean and May Duke, have now come in.

TO CORRESPONDENTS.

\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

N.B.—Many questions must remain unanswered until next week.

KILLING WOODLICE (*J. Mackenzie, M.D.*).—We know of no better plan of getting rid of these pests than boiling them, where it is practicable to do so. In places where boiling water cannot be used for fear of spilling plants, there is no better plan than laying traps for them, and keeping several toads and frogs in the house. Constant attention to trapping and scalding them with hot water, and keeping a supply of toads and frogs, will soon bring them to grief. You are quite right in thinking early thinning of fruit is necessary. Grapes, especially, should be thinned, many of the varieties as soon as they are set—indeed, we this year thinned some before they came into bloom, and we have no doubt that it will be very beneficial to them. With regard to Peaches, Nectarines, &c., the fruit-buds should be well thinned before they open their blossoms. The best time to do this is when the buds are about the size of a small barleycorn.

PEACHES, NECTARINES, &c., AGAINST A PARK PALING (*An Old Subscriber*).—We do not think that either of the above fruits would do well against a park paling unless the boards fitted closely together, which is generally not the case with the pieces of wood park pallings are made of. They are usually split or cleft, instead of sawn. Pears might do against a fence of this sort, but why not build a wall if fruit-growing is an object with you? The wall would not cost much more than double the expense of the park paling.

LEFORD HORTICULTURAL SOCIETY (*Farnborough*).—If the names of the Directors are not accepted as a guarantee that it is a sound Society, nothing that we can say would be more influential. If the Directors ever have cause to be dissatisfied with the management they are too practical not to apply a remedy.

WATER-PROOFING (*A Donegal Subscriber*).—To render the sail-cloth tubing waterproof it should be painted over with Indian-rubber dissolved in naphtha. Your plant is *Hydrothamnus fasciculatus*.

BUNCHES OF GRAPES FALLING (*R. G. B.*).—They are very severely shranked. It usually arises from the roots being torpid. If outside they are probably too cold, and if inside they have probably descended too deep. In the former case we should cover the border at night, and remove the covering during sunny days. In the latter case we should remove the soil, so as to bring the upper roots within 3 or 4 inches of the surface, and use tepid water when they require moisture. It is not improbable that you have applied water too abundantly and too cold.

**CATERPILLARS ON WHITE THORN** (*A Subscriber*).—The "cobwebs" containing blackish caterpillars are the larvæ of the small Ermine Moth. The only remedy we know is to have them picked off and crushed. This would quickly be done by children, and they might be rewarded for the number of the white parent Moths they caught. These Moths will appear in a few weeks.

**STOCKS** (*B. N.*).—The *Ten-week* is so called from the time elapsing between its sowing and blooming. It is *Mathiola annua*. The *Brompton* is *Mathiola simplicicaulis* of some, but is generally considered to belong to the same species as the *Queen*, which is *M. incana*. The *Intermediate* is *M. græca*, and so called because its leaves are smooth, so as to place it as an intermediate between the *Stock* and *Wallflower*.

**TRELLIS FOR SION HOUSE CUCUMBER** (*J. B.*).—The trellis will do very well. Cucumbers are much better in every way grown on trellises than in any other mode. If we had had the forming of a trellis we should have avoided the dip in the centre. It should have been put in at equal distances from the glass all over—say 16 or 18 inches. The night temperature is not quite enough to grow Cucumbers well, it should be from 65° to 70°. The day temperature will do very well.

**VINE LEAVES SCORCHED** (*J. H. Cook*).—The cause of your Vine leaves scorching and curling up is want of moisture at the root, and we should think that you have not been in the habit of giving air early enough in the morning. If this is the case the sun has done all the mischief. To prevent further injury apply plenty of water to the roots and give more air, and earlier in the morning; if the weather is bright, open the front lights; if dull, only open those at the back of the house. For further instructions see an article in another page.

**CREEPERS FOR THE NORTH-EAST WALL OF A HOUSE** (*A Subscriber*).—We should think a slight projection over the main walls rather an advantage than otherwise, especially for some of the more delicate kinds of creepers, because it shelters them well from the wet. The following is a list of the kinds we would advise you to plant:—Several of the best variegated forms of Ivy, Ampelopsis, or Virginian Creeper, *Bignonia capreolata*, *Clematis sempervirens*, *C. Hendersonii*, *C. montana*, *C. vitalba* (the *Traveler's Joy*), *Jasminum officinale*, *Lonicera grata* (evergreen), *Wistaria*, white and blue. Some of the climbing Roses would also answer well for the purpose, such as *Ruga*, *Garland*, *Crimson Boursault*, *Dundee Rambler*, *Rampant*, &c.

**BOTANICAL QUERIES** (*A Constant Subscriber*).—We think you cannot mean what your request includes—viz., "The orders and tribes into which Geraniaceæ are divided, with their specific names and characters." To do this we must go through all the species in the genera *Erodium*, *Geranium*, *Monsonia*, *Sarcocaulon*, *Pelargonium*, and *Hyosecharis*, and if we included, as you add, "bedding Geraniums," we should have to fill a volume. We shall publish the report of the Royal Horticultural Society on bedding Pelargoniums, which may answer your purpose. It is quite impossible to answer such sweeping questions as you ask about Pæonies and Irises, number of species, colours, &c., You must refer to Loudon's "Hortus Britannicus," or the "Cottage Gardener's Dictionary."

**DISPOSAL OF MARKET-GARDEN PRODUCE** (*Wonerth*).—Apply to a salesman, or advertise.

**SIBERIAN ARBOR VITÆ** (*A Reader*).—We are not surprised at your uncertainty about this tree, for not only are there discrepancies in nurserymen's catalogues, but in the writings of botanists. We believe that *Thuja plicata*, *Wareana*, *sibirica*, and *tatarica*, if not identical, are compact-habited forms of *Thuja occidentalis*. There are three species of the *Halesia* or *Snowdrop Tree*; shrubs about 8 feet high, with white, Snowdrop-shaped flowers; natives of North America. Gordon's "Pinetum" might suit you.

**INSECTS** (*A New Subscriber*).—The insect sent from the Vine is not the Vine bug. It is the old enemy, *Otiorynchus vastator*. Hunt for it after dark with a lantern, having first laid a sheet of paper under the tree. The small shoot was so dried up and crushed that we could make nothing out of the apparently white eggs.—W.

**PORTABLE BOILER** (*A Subscriber*).—We know of no maker of the boiler of which we gave a drawing at page 269. It is an American invention, and we noticed it because we think any iron manufacturer who made them in this country would find a good sale for them. If you applied to some such manufacturer who advertises in our columns he would tell you for what price he could make you one.

**SPOT ON CAMELLIA LEAVES** (*Elizabeth*).—We should think the spot on your Camellia leaves has been caused by the sun. The plants should never be placed in positions where the direct rays of the sun can strike them.

**SEEDLING PELARGONIUMS** (*P. Drummond & Co.*).—Your seedling Pelargoniums appear to be good, but neither of them is new in colour. The pink one is very bright, but there are many as bright. We should prefer seeing plants of both seedlings before giving an opinion of their merits. The petals had all fallen, therefore it is impossible to speak of the form of the flower and size of the truss, &c.

**ALPINE AURICULAS** (*Tyro*).—An Alpine Auricula has the outer edge of the petals shaded by a mixture of two colours not separated into distinct bands of colour, as in the edged varieties. The paste round the tube is yellow instead of white, as it is in the edged and in the one or self-coloured varieties. Your specimens are—1, *Cerasus padus*, or Bird Cherry; 2, *Halesia parviflora*, or Small-flowered Snowdrop Tree.

**PLANTING AN ORCHARD IN THE WEST OF IRELAND** (*M. A. C.*).—It is difficult without knowledge of the locality, to point out what would be the best kinds of fruits to grow, as from an acquaintance with the fruit-growing counties near London, we know that even the distance of less than half a dozen miles makes a great difference in the character of soil as regards its suitability to certain varieties of fruits; in other words, the same kinds do not prosper equally well at places but a short distance apart, even when soil and situation seem to be alike. We may, however, say, that as a universal rule or nearly so, Cherries do best in a grass orchard, while other fruit trees do not seem to be injured by the ground between them being cultivated, provided the soil be moderately deep, and the subsoil not objectionable; but as the trees grow older, it is usual in the orchard districts to do away with the under-cropping and sow the ground with grass. To a perfect stranger we would say that he may plant five-feet standard Apple and Pear trees 20 feet apart, or if 24 they would be none the worse; or if he prefer an orchard of dwarf trees, 15 feet might do; but then all hopes of having it in grass must be abandoned. We have seen trees spaced 30 feet apart with advantage, and also seen less than 12 feet allowed. We fear we cannot give him much information as to kinds, but if he plant Lord Suffield, the New Hawthornden, Dumelow's Seedling, Sturmer Pippin, and Winter Queening, he cannot well do wrong; but for table kinds and also for Pears he had better consult some skilful cultivator in the locality, whose experience has enabled him to say what are likely to do well, and what not, and although "M. A. C." need not necessarily act on all the information so gained, he may benefit much thereby.

**DUBBIEU ON FRUIT TREES** (*Critic*).—We never did nor can we recommend Mr. Wardle's translation of this book. Mr. Wesley's advertisement makes an erroneous statement. The quotation is from a correspondent's communication.

**NAMES OF PLANTS** (*W. Clark*).—*Asplenium hemionitidis*. (*J. B. Boyd*).—The Fern is apparently a sterile frond of *Polybotrya cylindrica*, and the leaf we think is of *Corynocarpus levigatus*. (*T. C. D.*)—1, *Saxifraga sarmentosa*, L.; 2, *Sparmannia africana*, L.; 3, *Habrothamnus fasciculatus*, Miers; 4, *Spirea salicifolia rubra*, Hort.; 5, *Spirea trilobata*, L.; 6, No flower. (*Z. C.*)—1, *Coronilla emerus*, L.; 2, *Viburnum lantana*, L. (*Cissie*).—We cannot name plants from their seeds. 1 is a leguminous seed, perhaps of the genus *Erinacea*. 2 and 3 are, as you suppose, the same, and are fruits of a species of *Rhamnus*. 4, Fruit of *Zizyphus lotus* (?) (*Bank-siana, Surbiton*).—The leaf sent may belong to *Lomatia salicifolia*, Br., but we cannot decide without better materials. It was introduced by Messrs. Loddiges in 1808.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending May 27th.

POULTRY, BEE, and HOUSEHOLD CHRONICLE

POULTRY JUDGES AT BIRMINGHAM.

KNOWING how willing you always are to open your columns for the discussion of any important matter in reference to poultry, I am sure the question of appointing Judges for the great Birmingham Poultry Show is of such importance that you will willingly find room for the correspondence this letter may lead to. I am not an unsuccessful exhibitor at Birmingham, therefore I can write upon this subject without the sarcasm in which so many writers indulge; I am not going to find fault because I do not win, for I have

rarely shown at Birmingham without taking prizes, and when I have been beaten it has always been by birds superior to my own; and I am not going to find fault with the Judges that have hitherto acted, although I have not the least doubt that many errors have been made, and whoever acts as Judge at a show of such magnitude as Birmingham must be clever indeed to judge it without a mistake or a complaint.

Some very angry letters have appeared strongly condemning the appointment of judges who are dealers in poultry, and the grounds of objection are too strong for my pen to attempt to argue against; but I cannot but confess that I should regret to see Mr. Baily's name erased from the list of Birmingham Judges. There are many varieties

of fowls of which I believe Mr. Baily to be a most important judge. The responsibility of the Judges at Birmingham appears to increase every year, and will considerably so this year, in consequence of the increase in the prizes, and many valuable silver cups are given in addition by the amateurs. I do think that if a large amount of valuable silver plate is added to the prize list by the exhibitors, the Council ought to consider their wishes as to who shall award those important prizes, and I wish most respectfully to ask the Council, through the medium of your Journal, how it is that we are not allowed the assistance of the most satisfactory judge in the kingdom, Mr. E. Hewitt?

I am a constant reader of your Journal, and notice that nearly every show that takes place is judged by Mr. E. Hewitt, and it is very rare to hear a complaint, and I am satisfied I express the unanimous view of the poultry amateurs of England, when I state that it is their most anxious wish to know that he will act as one of the judges at our next Birmingham Show. I trust the Council will take into full consideration this appeal, and unite the name of Mr. E. Hewitt to the list of Birmingham Judges, whose name I am sure will restore much of lost confidence, and will prove a most satisfactory addition.—A BINGLEY HALL EXHIBITOR.

[The writer, as he intimates, is one of the most successful of exhibitors, and we can state emphatically that we know that the Council of the Birmingham Show would gratify exhibitors generally, and remove much obloquy from themselves, if they added Mr. Hewitt to the Judges of that Show.—Eds.]

#### BRAHMA POOTRAS—PRIME AGE OF DUCKS.

IF "WILTSHIRE RECTOR" is not much attached to his Cochins I would advise his trying Brahmas, they are the same gentle sensible creatures, good layers, good mothers, and good on the table. I have tried Cochins, and liked them very much, but I think the Brahmas are superior. They will fully appreciate a run in his neighbour's field, but they will not fly over a fence into any garden, however tempting. My only grief is that they must be killed sometimes, for it is painful to give the order, when they walk about with you like dogs, and trust you so entirely.

I should be glad if any one would tell me if it be better to keep Ducks until they are two or three years old, or to rear young ones every year for breeding.—M., *Sunny Vicarage*.

[Mr. Baily fully endorses all you say about Brahmas. They are, in his opinion, superior to Cochins, and thinks that those who say they are identical have a great deal to answer for. A second-season Duck is better than a first, and therefore we advise you to keep those that have proved themselves good ones. We often keep them for four years or seasons, and have no reason to repent it.]

#### HATCHING THIS SEASON.

I do not for a moment suppose that any persons having the least claim to respectability would play any tricks with the eggs they dispose of for sitting, but as I have this season purchased sittings from some of the best yards in the kingdom, I will, with your permission, give you the results of each sitting.

On the 12th ult., the second day after receiving them, I put a dozen of Capt. Heaton's celebrated Buff Cochins under a very steady hen in a basket, with 3 inches of sand at the bottom, and a turf on the sand. When two days overdue I examined the eggs and found all bad but one, which contained a chick, nearly matured, but dead.

On the 24th inst., I have a sitting of Mr. J. Baily's Spanish due, and will also with your permission send you the results.

I may state that out of a sitting of my own, Partridge Cochins, due on the 13th inst., I only hatched four, nearly all the others seem to have died in their shells some few days before due.

I am told by all my friends (amateurs like myself), that my houses and yard are all that can be desired. Of one thing I am certain, that they are scrupulously clean, yet somehow or other I have been singularly unfortunate with

all my sittings at present. Will you inform me if cocoa-nut fibre refuse on the ground is objectionable for sitting instead of short straw, as recommended by Messrs. Crook?—PERCY CROSS.

[We shall be glad to hear of your progress, and to advise you as you go on. This has been an exceptional hatching-time: we know many instances in which eggs have failed where the previous sittings from the same yard, and under the same management, hatched twelve or thirteen. When your chickens die in the shell it is from being too dry; moisten every egg for six or seven days before hatching. We never heard of short straw for a nest, nor do we in any way approve of baskets for sitting hens. Let your nests be on the ground, put a moist sod for the bottom, over that you may put straw enough to keep the eggs in, but not short straw. If we wanted to insure disappointment in hatching, we would advise to set the hens in baskets partly filled with short straw.]

#### DOUBLE EGG FERTILE.

I SEE in a letter signed "CHANTICLEER" a doubt thrown out as to whether a double-yolked egg is less prolific. I hasten to inform "CHANTICLEER" and your readers that a few days ago an egg (Dorking), set by me produced two chickens. The egg was chipped and one chicken partly got out of the egg, but whether from want of room, or from being crushed against each other by the hen, they died before getting quite clear of their narrow home. Both chickens were well grown, and looked healthy.—REV. E. C., *Walton Parsonage*.

#### THE DERBY CANARY AND ORNITHOLOGICAL SOCIETY.

HAVING read your remarks upon my recently-published "Handbook, &c., on Canaries and other Birds," which has found favour with many breeders in different parts of England, and to a certain extent meets with your approval, allow me space to reply. As you have "brought me out of my shell," it is quite natural I should have a "chirp" or two, and will leave the subject to the opinions of the many breeders as to whether your remarks on my book have not been made without fair consideration as to what it was intended for. I endeavoured to prepare my pamphlet with care, not only for the benefit of the breeders in this district, but also to afford the fanciers in other towns an opportunity of learning what the Derby breeders have done, so that it might act somewhat as a guide to them, but never intended it as of "interest for the general reader."

I am as great a friend to the "general diffusion of the Canary fancy as any man breathing, and when I wrote the eighth rule, that "No person is admitted as a member of this Society unless residing in the county or borough of Derby," knew full well what benefit I was affording to the members in this particular locality. It was not intended that a code of laws suitable for a local society should be also suitable for an All-England show; and as to your expressing "a regret at this exclusiveness in these days of railroads," the very fact of some of the Derby breeders being able, well able, to bring out also an All-England show annually, second to none in the kingdom, proves your remarks against the eighth rule of our local society to have been made without a knowledge of what actually takes place in Derby towards promoting the extension of the fancy, facilities being given to the breeders and fanciers in all parts for availing themselves of the railroads.

I know full well the anxiety and attention that has been devoted towards making the Derby local Society what it is, and I feel proud in saying there is not existing another Canary society of a local kind that can excel ours. The Committee of the Derby Society have at all times been willing to render assistance to any breeders wishing to form a club in any other town, and what effect has the formation and encouragement of local shows in different parts of England? Why, they act as feeders and supports to All-England shows, by birds being sent for exhibition. They likewise cause an increase of breeders, and the more breeders and fanciers the greater the chance of the classes

being well filled with good birds, and if the fancier be one who gives his mind to the cause, he will soon cast on one side mongrel stock for first-class blood. My object is to increase the love for birds. As a breeder I have had much practice, and have with my pen publicly, and more especially privately, done what I could to further and encourage the study of birds, as to which fact many gentlemen (amateur breeders) can bear me out.

The remarks on the Belgian birds, and the classification of some of them, savours so much of what I have before had to contend with, that I could not prevent a smile on seeing a signature at the foot of an article in the same Number of your Journal, and thinking of past remarks respecting the Belgian birds, the kinds exhibited at every All-England show. As to the erect Belgian, or the Dutch birds, I like to see them, and would ever be willing for classes to be set apart solely for them. It would not do for marked or ticked Belgians to be classed with variegated Belgians, for the all-important reason that the marked or ticked birds are mostly bred from clear birds, and possessed of pure Belgian properties, fully equal in blood to the clear birds. The variegated Belgians are not so good in true Belgian form, and how is it possible to correctly judge a straight bird (or one not possessed with good back and shoulders), evenly variegated, with one only slightly ticked or marked in feather, and first-class in other respects? And, again, it would never do to have yellows and buffs judged together in one class. You say, "Would it not be better to have one standard for the best marked pied Belgians?" What advantage, I ask, can there be in throwing several classes into one whilst we have such choice specimens entered in each class? And while contracting the Belgian classes, you advocate new classes for Goldfinch Mules—namely, dividing them into clear and pied classes. I ask you how many clear Jonque or yellow Goldfinch Mules would be likely to be brought forward? I know, perhaps you do, there would not be such difficulty in finding two or three, or perhaps more, clear mealy Mules, but the two classes would be miserably weak. I venture to say that to the clear Jonque Mule class there would be said, "No entry."

In conclusion, my hints about cats apply generally, and not to your pussy, which may have received a superior education. I say, again, cats are not to be trusted with birds. It is against their nature not to catch and kill them. Your cat is one amongst hundreds for her merciful kindness towards the feathered tribe.—GEO. J. BARNESBY, Derby.

[We are glad to receive Mr. Barnesby's explanation, and also to hear him speak so well of the erect Belgian or Dutch Canaries, but as they were not included in his book we could only draw attention to the omission; but Mr. Barnesby's reasons for not classing ticked or marked birds with variegated, do not seem satisfactory. If, as his argument seems to imply, the one are straight and the other hunch-backed, it is an additional reason why the classification should be based on form, not on colour, as in this case it seems to us a difference without a distinction. In Pies the preference would be given to the best and most evenly-marked bird without reference to the ground colour. It is only when two are so nearly equal that Jonque would take the precedence of mealy. Clear Mules cannot compete in the class for piers, they are certainly out of place there, but are too valuable to be passed over, though they may be few and far between.

As regards the cats, if only stray cats are met, then, of course, every care must be taken to guard the birds from them; but the assertion made was too sweeping. It is surprising how soon cats may be instructed to live in peace with all domestic pets, and hundreds of such cats may be found among the bird dealers in London.]

#### DESTROYING THE QUEEN OF A SWARM.

To-day I had a swarm of bees from a stock which had been supered with a shallow straw hive containing several small combs, commenced by the bees last year.

I wished to prevent swarming, and for that purpose I stood at the entrance of the hive as soon as the swarm began to issue, and seized the queen as she came out. I confined her

for a few minutes, but fearing that destroying her would only defer swarming until another princess was raised, I set her at liberty, and after flying about for several minutes, she joined her subjects which had clustered on a neighbouring tree. The swarm was then hived in the usual manner.

I should like to know what would have been the probable result had I destroyed her majesty. I know the swarm would have returned, but would the bees have taken to the super, or would the next young queen have led them off again?—S. E. B.

[We think you were right in not attempting to thwart the disposition to swarm. Had you destroyed the old queen the swarm would probably have issued again a few days later under a young one.]

#### HIVES WITH ENTRANCES AT THE TOP.

I was not a little amused to find at page 352 that Mr. Henry Stuttle (C. Williams at page 277, his previous communication on this subject) wandered from his description of "Hives with entrances at the top" to have a hit at bees' enemies, "the very greatest their inexperienced masters" in general, including your Renfrewshire correspondent in particular. I most decidedly take exception to figure in such company, having always a great repugnance to the black list of the enemies of our little favourites, even although your correspondent be polite enough to add "myself included." Had he been a more careful—probably an older—reader of this periodical, he might have saved his criticism, seeing that my stock being reduced to beat-outs arose from no blunder in practice, but solely from their being contaminated by foul brood imported from Devonshire; on the contrary, my apiary has, with this exception, been on the whole a most prosperous one. He, too, was most unhappy in quoting your "Renfrewshire correspondent" as a sample of the "inexperienced," when, singularly enough, that correspondent was the very one who years ago drew attention in these columns to all the advantages of "end communications to supers," the first discovery on which Mr. Stuttle plumes himself, and still more singular, was long before familiar with moveable bars, and had them employed in "hives with entrances at the top," his second discovery, possibly about the time Gordon Cumming was firing away with the old rifle.

Although practice does not invariably make perfect, still it often familiarises one with many odd things, and amongst the rest I may be permitted to describe how I came to work and discard hives with entrances at the top.

What induced me first to take a special interest in the honey bee was a number of years ago opening up a couple of the many stocks of bees which from time to time had established themselves in the roof of our house; each colony occupied the vacant space between the "couples" or beams forming the roof, their combs being attached to the inner side of the "sarking," or boards to which the slates are nailed externally, from where they were carried down to the lath and plaster, a depth of about 10 inches. To compel the bees to extend their combs out into the boxes I had prepared and set up to fit the square cut out of the lath and plaster, I had the spaces below the combs boarded off level with the bottom of the boxes; their ends fitting into the spaces were, of course, quite open, and top and bottom fitted with bars and slides for supering and nadiring, with glass fronts and thermometer for observation. The plan succeeded so well that the very first season I took from these two hives half a hundredweight of beautiful honey. The following season to prevent swarming I had to go on nadiring, till latterly I had one of the colonies occupying four roomy breeding-boxes, it consequently followed that the bees wrought exclusively through the original entrance at the top, as I could not cut up the ceiling for every fresh box added; besides, from the level of the roof each additional one was brought further from it.

I had ample opportunities of watching all their proceedings through the glass fronts, and saw plainly the disadvantages of the entrances at the top, they were very much oppressed with heat, and I did not feel disposed to open a space below to communicate with the upper entrance, knowing full well the dislike of the "Sanitary" bee "Commissioners" to all

draughts, particularly through the brood combs of the hive's centre; and there was the constant liability to find pollen, and more rarely, brood in the supers. Often have I taken a chair and sat and watched the industrious little workers dragging their heavy burdens to the top, and failing to force a passage up through the crowd of nurses. Frequently have I noticed the dead workers, grubs, drones, or wasps, drop in the ascent, to be again seized upon and dragged upwards. However, these were minor evils in comparison to the one to which they had to yield. Although with great labour they managed to keep their hives pretty free of dead, they were unable to do so in the case of the small débris. To give them all the aid in my power I had the bars and slides forming the bottom of the lower boxes fixed to frames, and these again attached to the boxes with screws, so that on a cold day I could slip them off for a hurried clean. Unfortunately, however, the topmost boxes and the shelves in the roof were beyond my control, and in the débris there deposited grubs bred rapidly during warmish weather and took wing as wax moths, speedily reproducing their kind. My indefatigable little favourites did everything in their power to combat this new enemy, even to the cutting out portions of their combs, but they so multiplied, fitting through the hives in bands, that latterly the bees became dispirited, and I was most reluctantly compelled to abandon bee-keeping in high latitudes, under the impression that "hives with the entrance at the top" have to the inexperienced only novelty to recommend them.—A RENFREWSHIRE BEE-KEEPER.

#### DRIVEN BEES.

Do the following circumstances prove that I have failed in driving out a queen with her subjects? On Monday, the 15th inst., I drove a swarm about noon, and placed the hive in the position of the old stock. On Tuesday the swarm all left the hive, but in a few minutes returned. On Wednesday, Thursday, and Friday they swarmed each day, and hung upon a bush close at hand. I hived them in a fresh hive (a straw one, for I have nothing else), each day, and once with three pieces of comb in it made last year. Being tired of this daily swarming and hiving, on Friday night I united them to another swarm which I had driven on Wednesday. However, it appears that they gave their new friends some of their roaming disposition, for all came out together on Saturday, but after about a quarter of an hour returned to their hive, on the outside of which they have now been hanging for a day and a half. Now, if it is probable that there is no queen among them, what am I to do?—C. H. L.

[As the queen is sometimes one of the last to ascend, it is just possible that you failed to expel her, and this would account for the bees so repeatedly deserting their new domicile and attempting, of course unavailingly, to return to their old one. Instead of risking the life of the queen of the second driven swarm by uniting it to the wanderers, it would have been much better to have put the one last driven in its old place, and shaken the errant swarm into the well-filled hive which the others had just quitted. If the bees are now without a queen the adoption of this course with a third stock is the best remedy.]

#### NATURAL SWARMS.

Not a few of the bee-keeping fraternity, more particularly beginners, are doubtless looking forward to and watching for that uncertain thing natural swarming. Presupposing that most of them have guarded against that very worst enemy—damp, and that all have succeeded in getting their stocks well forward, I purpose offering a few hints on the subject.

In the first place he must be a very casual observer who does not notice that bees are in want of something like nadering when the hives appear chokefull, and it is certainly bad policy to allow the bees to provide entirely for themselves at this time of the year without administering a little food. Bees which have been well forward previous to a period of cold weather are sure to retrograde without it, whilst backward hives with a little assistance are steadily

progressing. It is not at all times easy to know beforehand the time of a swarm issuing. I have known bees swarm before the hive was quite full or even a royal cell formed, whilst, on the other hand, I have seen them lie out for six weeks and never swarm at all. In the first case, it is prudent for every bee-keeper to be on the watch, and the second case, every judicious bee-keeper should prevent. I would here recommend artificial swarming, as no skilled bee-keeper will allow in swarming-hives, and would equally scout the idea of even seeing his bees become crowded in storifying ones, without additional room. Seeing, then, that the exact time of swarming cannot be hit upon, it is best to be on the watch, and more particularly so on account of bees swarming at all hours, night and day. This at first sight may appear erroneous, nevertheless it is the case. Although at night they do not fly to some spot contiguous to their hive but cluster on the outside of the hive itself, yet it is still the swarm, and if not taken away then two important ends are defeated—viz., honey-gathering and breeding.

The question of course arises, How does breeding stop? I answer, Simply because the queen is on the outside of the hive with the swarms, and there remains until she dies or is killed by her subjects, young queens being brought forward in the ordinary manner. Then is it that piping is heard before the issue of a first swarm.

A friend of mine, who keeps bees on the old-fashioned system of "let alone and they will work their own work, and will swarm when they are ready," had last year out of six stocks only two swarms. He would not be advised to use artificial means, or even so much as to turn up a single hive in order to ascertain its state, but only went about wondering what was the matter, and why there were so many queens thrown out, and satisfied himself with the idea that at certain times of the year bees retained a great number of queens. I could relate many more similar cases, but deem it unnecessary.

It is not a bad plan, in order to keep bees from lying out; to place on the face of their hive a smooth board fixed close to it by a mortice cut for the alighting-board to pass through, and so close to the hive that not a single bee can get between them.—A LANARKSHIRE BEE-KEEPER.

#### OUR LETTER BOX.

**GAPES (Hamburgh).**—Give your chickens a fragment of camphor about the size of a pea every night at roosting-time. Put a piece of camphor into the water they drink from. We really have no data on which to found advice about H. Atkin's pictures.

**DIARRHŒA IN CHICKENS (R. B.).**—Give each chicken half a grain of opium, three grains of powdered chalk, and half a grain of ipecacuanha in a pill daily until the diarrhœa is stopped, feed on bread sopped in ale, give plenty of lettuce leaves, and free access to a dust heap.

**REARING YOUNG TURKEYS (A Constant Reader).**—Turkeys require a dry spot, well exposed to the sun, but near to a bank, or small covert, or hedge-row. They want dust. The best food is boiled egg, ants' eggs, cooked chopped meat, bread and milk, dough mixed with milk, and made of flour of equal parts of oats, barley, and beans. Onion tops or garlic should be mixed in all their food when young. They should be chopped fine.

**SUDDEN DEATH OF CHICKENS (A. J. P.).**—When chickens die suddenly it is mostly from injudicious feeding, or from access to some poisonous food. Move your chickens as far as you can from the spot where they die, and give them bread and strong ale.

**CLEAVERS (A Constant Reader).**—Cleavers, Clivers, or Goose Grass, is a plant known to botanists as *Galium aparine*. It is one of the commonest of weeds, growing on moist banks. The hooky hairs upon it cause bleeding when drawn over the tongue. It is, as you say, often recommended to be chopped up and mixed with the food for young turkeys.

**TEACHING A STARLING TO TALK (W. C.).**—It is the common Starling that talks. We have but one British species, except the rose-coloured, which is a rare visitant to this country. By constantly repeating to it the words or short phrases you wish it to say it will learn them, and in the same way it may be taught to whistle tunes. When young the bird is very easily reared; by feeding it on raw meat cut up, occasionally worms, bread soaked in water, and hemp seed.

**PARROT PLUCKING OUT ITS FEATHERS (Idem).**—The reason of the Parrot plucking out its feathers is, most probably, irritability in the skin, caused by improper food of a greasy nature, such as meat, bones to pick, and too much hemp seed. Let it have a shallow pan with water to bathe in, and on a warm day take a watering-pot with a small rose and give it a bath.

**VARIOUS (B., Compton Gifford).**—The bees which frequent your deserted hive are scouts sent out by some of your neighbour's stocks that are about to swarm. They may possibly herald the advent of a stray swarm, or their visits may continue during the swarming season, ceasing only when it is entirely over. Buy Taylor's "Bee-keeper's Manual." Use Payne's improved cottage-hive for ordinary, and the Woodbury frame-hive for scientific bee-keeping.

**TRANSFERRED BEES (A Beginner).**—Your hive appears to be going on well. A glass may be put on at once.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 69.8°, and its night temperature 47.8°. The greatest heat was 90° on the 6th and 7th, 1846; and 12th, 1842; and the lowest cold, 34°, on the 9th, 1862. The greatest fall of rain was 1.48 inch.

A FEW NOTES ON CROPPING A KITCHEN GARDEN.

MUCH pleased was I with the remarks on "Kitchen-garden Cropping," by "BURNTWOOD, P. D." (page 377), whose mode of obtaining so much produce from a limited space deserves to be widely known, not only because it shows what may be done, but also as it may induce others similarly situated to give an account of their practice, and

as cases differ widely, much useful information may thus be elicited. It is, however, well to remember that there is in general a wide difference between the practice of the country and that of the suburban gardener, the latter having to make the most of a limited space, though to compensate for this disadvantage he can in most cases obtain plenty of manure; while, on the contrary, the country gardener has often more ground at his disposal, but is obliged to be more sparing of manure. Now, although it is not exactly true that manure will do anything, it is nevertheless a very powerful agent in producing some of the more common vegetables. Those of the gross-feeding class can be urged into growth by the aid of this powerful auxiliary where the natural ground from previous hard cropping would seem to claim a rest, but plenty of good dung restores the worn-out soil, and another crop is obtained. Most vegetables delight in rich soil, and may therefore be grown on the forcing system just described; but the practice of the rural gardener is somewhat different, he uses manure sparingly. Very likely there are large grass and arable fields in his immediate vicinity having a claim to a share of the manure-heap as great as his, and he is obliged to be content with a less quantity than falls to the lot of his brother craftsmen living near the great metropolis. There is one practice, however, that is applicable to both, and that is the rotation of crops, which is attended with the best results, and "BURNTWOOD, P. D." has very wisely introduced it into his system, and doubtless with good effect. I will also add one or two modes of cropping which I have found answer very well the double purpose of making much of the ground and at the same time affording the necessary change in cropping.

One of the most important crops in all gardens, large or small, is Cabbage, and with me this crop remains longer in possession of the ground than any other, except

permanent ones, such as Asparagus; in fact, the main crop of spring Cabbages, intended for use in May and afterwards, is generally planted in October on ground that has previously been devoted to Onions, but which has been trenched and manured. The crop usually remains fifteen or sixteen months on the same ground, and is not removed until the second February following its planting, the spring cutting of Cabbage being succeeded by abundance of nice little sprouts, which afford a supply of Greens up to that time, when, perhaps, the hardness of the winter may have rendered them no longer useful. The site they occupy is then dug or trenched, and, if possible, sufficiently early for the soil to be exposed to frost before it is again occupied. Potatoes or Scarlet Runners are then put in, but none of the Brassica tribe, and for a like reason we prefer not planting Cabbage with Peas, as we generally contrive to have one main summer crop of Peas on ground that has not had any of the Cabbage family upon it in the preceding season, as Broccoli is usually planted between the rows of Peas, to occupy the ground when the Peas are taken away. I may mention that if the rows of Peas are 8 feet apart four rows of Broccoli may be planted between, the rows nearest the Peas being only 1 foot from these. Of course care must be taken in gathering the Pea crop, and after the last gathering the haulm ought not to remain a single day. After its removal the ground may be slightly dug, and the space it occupied and the rows of Broccoli adjoining, may be refreshed with a liberal watering of liquid manure; and although the rows nearest the Peas do show a somewhat uneven lanky growth, they speedily recover, and by the end of autumn the crop is about uniform. Of course when this mode of cropping is adopted the Peas sown are those only which come into use not later than August, so as to give as much time as possible afterwards for the autumn growth of the Broccoli.

Returning to the Cabbage crop, from which the above has been a digression, there is nothing, perhaps, in which the practice of the private grower differs so much from that of the great market gardeners as in regard to Cabbages. With the latter it is not unusual to see a large breadth of Cabbages all of a size and all fit to cut at once, and after cutting, the ground is dug or trenched, heavily manured, and a fresh crop is upon it in less than a week. This would not suit a private family, where a great number of different vegetables are wanted at different times instead of a waggon-load at once: consequently the private grower must select the variety of Cabbage that is least inclined to run to seed, and also suit the time of sowing to the same end, so as not have any portion of his crop running to flower either before cutting or afterwards. He may also if he choose sow and plant a few Coleworts; but in general he depends more on the various kinds of Greens, Brussels Sprouts and the like, to carry him through than on Coleworts, which after all differ only in name from the side sprouts of the preceding Cabbage crop. It must also be borne in mind in cropping that the Cabbage tribe occupy a large space of ground,

more so than any other remaining there during the winter, and that the crop which is best to follow another cannot be so precisely determined upon beforehand as to pass into a rule. There are some crops, however, which it is advisable to avoid as a succession to the Brassica tribe, and one of these is Carrots. Potatoes, however, may do, and Dwarf Kidney Beans and Scarlet Runners, as well as Broad Beans, and if necessary a portion of the ground may be set apart for Celery, and the trenches being dug early and well manured, Lettuce or some other light crop may be planted upon the ridges. We have likewise often had summer Cauliflower there, and sometimes a small-topped Potato; but it is not advisable to plant anything that is likely to be late in coming off, for it must be borne in mind that the Celery is the legitimate crop, and its welfare must not be sacrificed for the sake of a temporary occupant.

The rotation of crops is a subject which has been often adverted to in these pages, but I may observe that circumstances frequently occur to derange any established rule, and it becomes necessary to make the most of the ground. A crop of late spring Broccoli may occupy some out-of-the-way place where it would be useless to sow Peas on account of the ravages of small birds, and when it might be too late to plant Potatoes, or, in fact, they might not be wanted there, whilst sundry reasons point out the desirability of planting the plot with winter stuff again. This certainly may be done, but the ground must be liberally manured, and, what is equally beneficial, it will have to remain two or three months of the early part of summer idle or nearly so; certainly a crop of Potatoes or Kidney Beans may in some cases be taken off the ground, but such crops ought not to remain longer than is absolutely necessary in order to insure a due growth to the winter occupants, and where ground is plentiful and manure less so, a rest in the growing season is beneficial. There are many other cases in which any established rule for a change of cropping must be broken through, and with little or no detriment to the vegetable grown, only it is necessary, as above observed, to avoid, if possible, crops succeeding each other that resemble one another in their requirements, as the Cabbage and Broccoli family all do; for although they may be made to do good service on the same ground for a few years, it is only at the expense of the manure-heap or their quality. It is the same with other plants, and as an example bearing on this point some flower-beds were once pointed out to me that were not at all satisfactory, the plants being as much disposed to die as grow, and plants of exactly the same kind had occupied the same beds for a succession of years or until the ground was sick of them, as the common expression is. Robust crops, like those of the kitchen garden when afforded plenty of good manure, are less likely to suffer, still a change is advantageous and may generally be accomplished without loss to the quantity of ground required for each crop, and with much benefit as regards the quality of the produce. I am sure "BURNWOOD, P. D.," will excuse my differing in some little details from his excellent paper, which I commend to the general reader, especially to those near large towns, where every inch of ground has to be made the most of.—J. ROBSON.

### LIQUID MANURE.

THE advantages accruing from the judicious application of liquid manure to various garden crops, have been so ably advocated, its value shown, and the results obtained by its use so often stated, that it may seem unnecessary to say anything more on the subject. It is not with a desire to depreciate the value of manure in a liquid form, nor because I have any discovery to impart, that I take the matter up; but to state my own experience with liquid manure as applied to most flowers, fruits, and vegetables usually cultivated in gardens. I have found that, great as the benefits derived by the horticulturist from judicious and reasonable applications of manure water really are, there is everything to dread from injudicious and unseasonable applications. It varies much, and it is so difficult to know how much to dilute it, in order to have it of the right strength, that it is dangerous in inexperienced hands. I will, therefore, note the various forms in which it has been applied.

DRAININGS OF THE DUNGHILL contain some of the soluble

and most fertilising constituents of the manure. Those who allow them to run to waste lose the ammoniacal substances, the alkaline matters, and the phosphates. To collect the drainings it is necessary that the litter or fresh dung be laid on a concrete floor sloping from the centre to the sides, and all round there should be a channel or gutter concreted or made impervious to water, and falling to the liquid manure tank, which should be sunk about a foot below the surrounding ground level, and be made so that no water but what comes from the manure-heap can pass into it. The tank is best of iron, with a lid perforated with half-inch holes, through which the liquid enters the tank, and is cleared of straw, &c. A tank 6 feet square, and 6 feet deep, will be large enough. This will hold all the liquid that will drain from the dunghill for three months, with the usual average of rainfall. If the drainage from the stables, the cowhouse, pigstyes, and slops from the house, are conveyed to the tank, it will be full in a month or so. I must observe that there is a great difference between the drainings of an exposed dunghill, and those from the stables and offices, in which urine enters largely. The liquid from the dunghill is much less strong, and may safely be applied in moist weather undiluted, or in dry periods diluted with an equal quantity of water. That from the stables, offices, &c., being much stronger, requires to be diluted with at least four times its bulk of water, and occasionally six times will not be too much. If, however, all the waste of a house pass into the tank, and is only so much dirty water, then it may not be necessary to dilute the liquid at all, but take care to have it weak enough. The liquid from stables, cowhouses, &c., and household offices is fully six times stronger than the drainings of a dunghill.

An iron tank is certainly expensive, but I have no hesitation in pronouncing such tanks the best I have had experience with. The next best, in my opinion, are those of stone fastened together with iron cramps, and the joints cemented, but prior to cementing the joints on the inside, ramming firm the soil at the sides, and at the bottom, too, beneath the stone bottom. The joints should be well cemented, and the tank covered with flagstones with a moveable lid or trap door. Stone tanks are equally durable with iron ones. Another durable tank is formed with brick sides and a puddled bottom, the sides outside the brickwork being also puddled, and having a closely-boarded top or flagstones as a cover. In forming these tanks care should be taken to make the bottom very firm, and to carry it beyond the brickwork, so that the puddling carried up outside the walls may unite with the bottom. Not only should good clay be used, but it should not be made very soapy by pouring water upon it; if it is sufficiently moist to be rammed or beaten firmly it will stand water better than very soft clay, for such is apt to crack in dry weather, whilst moderately dry clay can be made firmer, and is not so liable to crack. The joints of the bricks may be stopped with cement, but this is not necessary if the clay be rammed sufficiently. Tanks with brick walls laid in mortar, cemented over inside, and resting on a flagged bottom with the joints cemented, are excellent receptacles for manure water. Common casks may also be used for the same purpose; it is only necessary to dig holes and let them into the ground, previously making the bottom as hard as a barn floor with clay, and ramming clay very firmly round them, and if this is done effectually they form excellent reservoirs for either liquid manure or soft water. These tubs are best connected with each other by a lead pipe, and there is no fear of leakage if the clay is well rammed, and not very wet.

In addition to providing a tank, it is desirable to have water near at hand, with which to dilute the contents. It is not only necessary to provide tanks for manure water, but also for rain water from the buildings around, which is too generally conducted to drains. In order to provide against dry periods, the manure tanks must necessarily be in the ground; but those for rain water should be raised above the surface, and may consist of a number of tubs ranged side by side, and connected with each other by lead pipes. These elevated cisterns being furnished with a tap and hose, the garden crops can be watered without much hand labour, the pumping of water into the water-cart or cistern being avoided. A little contrivance, and some additional expense at first, would effect a great saving of labour, and watering

would become a pleasant instead of an irksome part of a gardener's duties.

Where it is proposed to make the most of liquid manure, a boiler should be set sufficiently high, and conveniently near to allow of the liquid being pumped from the tank into it, and when heated to boiling point the liquid should run into the water barrel without further pumping or hand carriage, or into an elevated tank, to be distributed by hose, sufficient water being added to make it of the right strength. To do this it is essential to have the contents of all accurately gauged, and a proof-stick made that will show, by notches cut in it, the quantity of water or liquid in each. It should show the contents in six parts, which will be sufficient for all practical purposes except one, and that is the syringing of trees with liquid manure. The proof-stick should for the latter purpose be divided into twelve parts, each part showing an equal volume of the contents. All the tanks, barrels, and their contents being known, it is easy to dilute liquid manure by taking some out of this and adding to that, and so on. For syringing it is essential to have an engine fixed on the water-barrel, in addition to a tap to let off the water; but there will be little necessity for carrying the water at all if hose be provided, and then the work is done much more expeditiously. The engine on the barrel will be found suitable for syringing trees, the barrel being situated on the walk. Messrs. Warner's engines, such as are ordinarily placed in buckets, are easily fixed in a water barrel, and they are excellent for freeing trees of insects, and refreshing their foliage, the water being thrown easily against the trees over a 20-feet border, by employing a longer lever or handle than is usually affixed to them.

In whatever way the water is conveyed, by hose, carts, or water barrels, it is desirable to lessen as much as possible hand labour, and never to carry water in a watering-pot where a quantity is required, and it can be distributed over the ground by its own gravitation. Carrying it in watering-pots is a great waste of time, and prevents many things, that would be all the better of water, receiving any. A few yards of hose will be of much assistance in watering a garden.—G. ABBEY.

(To be continued.)

#### GARDENERS CLAIMING PLANTS GROWN ON THEIR EMPLOYERS' PREMISES.

My gardener is leaving me. Contrary to my expressed wish, he has purchased plants and placed them in my greenhouse. It has been a point of disagreement with us for two or three years. He has lost many plants which I have purchased, and said it was because they were not good ones, and what he has bought he says has prospered. I cannot say in a very large stock what he has purchased, or what he has paid for them, or what he had given to him. He claims a very large number, or I am to pay him for them. Many of them so claimed I should have said were mine. I have no wish to be hard upon him, and should give him a present; but I cannot but think that he is at my mercy, and that he has no legal right whatever to them, even if he could bring witnesses to prove that they were his. I shall feel greatly obliged by a correct opinion on this.—NORTHUMBERLAND.

[Your letter contains matter of very great importance. A good deal of looseness and misapprehension exists on the subject. As a gardener of some experience now, I got into disgrace with an old gardener lately, because in a friendly way I told him he spoke rudely if not very imprudently to his employer. That employer admired some plants and beds, and in his generosity wished the gardener to collect cuttings and slips of them to send to his friends; when the gardener stated he might have flowers if he wished, but that he considered the plants and slips were his, as he had either bought or begged them himself. Being a kindly man the gentleman said, "Well! well!" and there the matter ended. The gardener insisted that as he brought the plants to the place and they cost his employer nothing, the employer had a right to the flowers for the cost of soil and attention, but had no right whatever to the plants. This, in fact, would be pretty much the same as asserting that a servant might carry on a sort of business on his employer's premises without ever asking that employer's

consent—a system which even with his consent" seldom answers long, just on the simple principle of the next to impossibility of serving two masters equally faithfully.

Now, as one who has had a fair share in getting up large quantities of plants in the easiest way, I would wish to impress it clearly and deeply on my brother gardeners that all plants or cuttings they may procure and carry home in the crown of their hats, specimen-boxes, or by whatever conveyance, are their private property until, and no longer, they have taken their place on the employer's premises, and are growing in his pots and soil. From that moment I have always believed that in right and in law they were as much his property as the horse in his stable or the paintings in his mansion.

This may moderate the zeal of those who wish something of everything they see when visiting a place, though that enthusiasm has often been the means of making the employer as enthusiastic as the gardener, and thus eventually helped the interests of our commercial establishments. Going direct to the market is generally the best in the end, though merely as a matter of neighbourly feeling I would not wish to see the custom abolished of reciprocally giving and receiving a few cuttings. It would be well, however, for gentlemen's gardeners to discard at once and for ever all idea of their having any property in such things after they are grown. In many instances where a gardener was leaving his place, I have been consulted whether some nice plants that he had reared from begged cuttings were not equitably his, and if he could not send them away before he left. In every instance I have said that legally he had no claim whatever, but that there could be no harm in stating the matter to the employer. In a few cases where our advice was neglected there was much unpleasantness. Even such matters as begging and lending should be done after a clear understanding; it will not do to depend on use and custom if you wish to maintain your honour untarnished. Such looseness of ideas may have partly arisen from the fact that some gardeners, and especially exhibitors, were at one time privileged to purchase for themselves novelties, and to treat the proceeds as their own property. There are many reasons why gentlemen in general should not permit such a course; but when it does exist, being a private arrangement, no one else has a right to interfere. Wherever such a custom prevails it would be most satisfactory for all parties that the agreement was not only clearly understood, but reduced to writing and duly signed; otherwise dissatisfaction, if not something worse, might take place at the termination of the connection of master and servant by death or otherwise.

A servant, however great his zeal, has no right to purchase goods for his master without his consent; and a gardener in thus purchasing should not go beyond the sum agreed upon, unless he has a commission to obtain what is wanted or what he deems necessary. He may purchase as many plants as he likes for himself and pay for them, but he has no right to bring them on his employer's premises without his consent and direct agreement to that effect, and without that agreement the plants become the property of the employer.

That employer, we presume, would be bound by the act of his servant in purchasing, if the act was not repudiated and the things purchased returned. I applaud the kindly spirit of "NORTHUMBERLAND" in wishing to deal equitably with his gardener, but if the gardener purchased contrary even to his expressed wish in the open market from a nurseryman, &c., I suspect he must pay for these plants. To escape all responsibility the practice should have been stopped and the plants returned. I say this because, from our correspondent's statement, there seems to me to have been a looseness of business on both sides. The servant had no right to buy without the employer's orders. He had no right to purchase with his own money, and bring the plants on his master's premises. He was anything but wise if he did so, for these plants became then his master's. But if the servant had purchased plants from a nurseryman, and the master ratified the act of the servant by paying for them, I believe that for a future purchase the master would be bound by the act of the servant; but in such purchases the bill should be presented at the first settlement. It would never do to keep these things in abeyance and make

an unlooked-for charge at a future time. Equitably the matter need be no difficult one, as there will be the tradesmen's bills and vouchers to refer to. Without such vouchers, and of somewhat recent date, the demand for payment or the right of removal would even equitably be out of place. Such a thing would sap the foundation of all confidence between employer and employed. Wishing to stand up for the rights of my order, I am forced to say that, according to the representation given by the employer, the gardener is "at his mercy;" but as the employer himself does not seem free from blame in permitting a continuance of what he disapproved, I trust that if, on examining vouchers, &c., he is convinced that his servant acted more from obstinacy or ignorance than from any worse principle, he will so far waive his legal rights as to treat his servant mercifully if not equitably.—R. F.]

(With all that Mr. Fish has said we fully concur.—Eds.)

### ROYAL HORTICULTURAL SOCIETY.

FLORAL COMMITTEE, May 30th.—Many very interesting plants were exhibited at this meeting, at which the seedling Pelargoniums of the year, always so attractive and so looked for by the florist, made their *debüt*, and among them were some first-rate flowers. There were not so many collections of plants as usual, this being a very busy season of the year, and such frequent exhibitions of plants, necessarily prevents the growers from sending them. The following certificates were awarded:—Mr. Williams, Holloway, received first-class certificates for an Orchid, *Promenæa* species (*citrina*), and *Statice profusa*, a very handsome plant with deep blue and white flowers, most useful for spring decoration; and second-class certificates for *Anætochilus nobilis*, a very pretty sort. A special certificate was, in addition, awarded for a fine specimen of *Lomaria gibba*. In Mr. Williams's collection were also *Maranta orbifolia*, *Smilax aculeata*, and *Cissus amazonica*. Mr. Veitch had first-class certificates for a beautiful *Maranta*, and *Amaryllis ignescens*, a new hybrid, one of the most beautiful in cultivation, bright fiery scarlet flowers, the centre of each segment having a clear white stripe. Had this *Amaryllis* produced a little better-formed flowers it would have been perfection. Mr. Veitch also exhibited two species of *Adiantum*, which were requested to be seen again. Messrs. Backhouse, York, received first-class certificates for *Asplenium inæquale*, a very distinct and beautiful Fern; *Lomariopsis heteromorpha*, a climbing Fern, from New Zealand, which changes the form of the fronds in its different stages of growth; *Pellea Wrightiana*, quite a new Fern; *Gleichenia cryptocarpa*, a new Fern from Chili, nearly hardy, and very beautiful; and second-class certificates for *Masdevallia* sp., a hardy Orchid; *Hycinthus amethystinus*, with very pretty, small, delicate blue bells; *Sarana Kamtschatica*, or *Lilium nigrum*, producing very dark almost black flowers. Messrs. Backhouse also sent *Trifolium alpinum*; *Ophrys fucifera*, from Prussia; *Linaria alpina*, an old but good rock plant, very pretty; *Aemone palmata*, with bright yellow flowers; and *Asplenium auricularium*.

Mr. Wills, gardener to Sir P. Egerton, Bart., sent *Verbena Maonetti* Princess Victoria, a very useful bedding plant, with deep rose-coloured flowers, one of the compact and close-habited *Verbenas*, like *Velvet Cushion*, probably from a cross with *venosa*—a first-class certificate was awarded it as a bedding variety; also *Pelargonium President Lincoln*, a *Zonale* with yellowish leaves, no improvement in its class. Messrs. Jackson, Kingston, had a first-class certificate for *Clerodendron Thomsoni* *Balfourii*, a larger-flowering variety than the species, which it much resembles, more compact in its habit, and a very free-flowering plant. Messrs. Osborn, Fulham, received a first-class certificate for cut specimens of *Robinia pseud-Acacia Decaisneana* with very beautiful rosy flowers, a great acquisition among flowering trees and shrubs. Messrs. Osborn also exhibited *Lilium pulchellum*. Mr. Pilcher, gardener to S. Rucker, Esq., brought a very fine specimen of *Odontoglossum citrosimum*, for which a special certificate was awarded. Mr. Eyles exhibited a fine specimen of *Cölogyne pandurata*, with a noble spike of green and black flowers, from the Society's garden. From the Rev. C. Fellowes came *Pelargonium Maid of the Mill*, not

equal to many others; and from Mr. Turner *Zonale Pelargonium Rising Sun*, with bright golden leaves banded with deep reddish brown zones—first-class certificate; *Pelargonium Neatness*, a pretty fancy variety; *Bougainvillea glabra*, and a box of beautiful cut *Roses*. Mr. Nye sent several seedling *Pelargoniums*. *P. elegans* was awarded a first-class certificate; the others were good flowers, but not sufficiently distinct. Among them were *Hero*, *Marian*, *Painted Lady*, which was much admired for its delicacy of colour, a pale rosy tint, but apparently a shy bloomer; *Mars*, *Jupiter*, *Purpurea*, *Atalanta*, and *Pluto*, all of which would have been thought much of a few years ago. Mr. Hoyle, of Reading, received first-class certificates for seedling *Pelargoniums* *W. Hoyle*, *C. Turner*, a very beautiful rosy carmine, excellent form, and good truss; and *Progress*. Mr. Stone, gardener to J. Day, Esq., was awarded a first-class certificate for *Phalenopsis sumatrana*, a new, distinct, and beautiful species of this interesting genus. Mr. Keynes, Salisbury, exhibited a seedling *Zonale Pelargonium*, *Wiltshire Lass*, with bright rose flowers in large trusses, a very free-flowering kind. Several plants were shown in a basket with moss, and produced a very good effect. A first-class certificate was awarded for this plant, which soon found a new owner, being purchased by Mr. Laing, of the firm of Downie, Laird, & Laing.

Mr. Sherratt, gardener to J. Bateman, Esq., exhibited a very curious and new Orchid. A special certificate was awarded to Mr. Bateman's collection of Orchids. A special certificate was awarded to Mr. J. Hodges, gardener to E. Wright, Esq., Birmingham, for cut specimens of very superb varieties of *Cattleya Mossia*. Mr. Bateman brought with him some fine specimens of the beautiful yellow *Rose Isabella Grey*, grown by one of his cottagers in his garden in North Staffordshire. The Committee having finished their labours in the Council-room visited the *Rhododendron* tent, and awarded seven first-class certificates to Messrs. Waterer for seedling *Rhododendrons* *Stella*, Mrs. John Clutton, H. W. Sargent, Charles Dickens, H. H. Hunnewell, Lady Clermont, and *Caractacus*, every one of which is of a first-rate character.

FRUIT COMMITTEE.—Mr. Rivers in the chair. Mr. Miller, of Combe Abbey Gardens, sent two specimens of *Meredith's Hybrid Cashmere Melon*, which were not allowed to be cut; and one of *Combe Abbey Hybrid*, a smooth, rich, yellow-skinned Melon of an oval shape. The flesh is white, and ripens well up to the rind, but, unfortunately, the flavour was not what was expected from Mr. Miller's description. Mr. Ingram of Frogmore sent a seedling *Cherry* called *Frogmore Early Crown*, which is about ten days earlier than *May Duke*. It is a small red variety, and when fully ripe of rich flavour. Mr. Archibald Fowler sent two dishes of *Castle Kennedy Fig*, a splendid fruit, large, handsome, and of excellent flavour, to which a first-class certificate was awarded. Mr. Chapman, gardener to His Highness Halim Pacha, sent an interesting collection of *Egyptian fruit*, to which a certificate was awarded, and among which the most remarkable were a delicious sweet *Lemon* and a *Loquat*.

SCIENTIFIC MEETING, May 30th, J. J. Blandy, Esq., in the chair.—The Rev. Joshua Dix having read over the awards of the Floral Committee, Dr. Hogg commented on the principal objects before the Fruit Committee.

Dr. Hogg remarked that the *Melon* shown by Mr. Miller, gardener to Lord Craven, was, on being cut, found not to be of good flavour, although stated to be excellent. *Melons*, however, were somewhat capricious in this respect. *Early Frogmore Cherry* from Mr. Ingram ripened ten days earlier than the *May Duke*, but *Belle d'Orleans* was earlier still. The collection of *Egyptian fruit* from Mr. Chapman, gardener to H. H. Halm Pacha, was next alluded to. The *Oranges*, it was stated, had suffered from the journey; there were also some *Sweet Lemons* and *Loquats*. The *Loquat* had been fruited in this country many years ago by Lord Bagot, and also by Mr. Bateman, and was to be seen occasionally in *Covent Garden*, but such fruit came from *Malta*, and were never so good as those grown in *Egypt* and the *East*. With regard to the *Castle Kennedy Fig* shown by Mr. Fowler, Dr. Hogg stated that it had existed in the gardens of the *Earl of Stair* at that place for nearly a hundred years. The fruit, as would be seen, was very fine, and, instead of

requiring four months to ripen when forced, it would do so in two, which was a very great recommendation.

The Rev. M. J. Berkeley in commencing his remarks observed that at the last meeting he had stated, in reference to an *Amorphophallus*, that it was fortunate the plant was not in flower, otherwise everybody would have been driven out of the room by its cadaverous odour. The spathes of some of the *Arum* tribe were, nevertheless, brilliant in colour, and, notwithstanding the generally poisonous nature of the order, the tubers of some of the species were edible. Even in our country those of *Arum maculatum*, commonly known as "Lords and Ladies," which is abundant in the Isle of Portland, were macerated, dried, and sold in London under the name of Portland Arrowroot. An *Arisæma*, after the poisonous alkali had been neutralised by fermentation, was also eaten in Sikkim. An unpleasant odour, it was remarked, was peculiar to many poisonous plants, and several instances were quoted; but in no order of plants did such an insupportable odour occur as in *Fungi*, and a coloured drawing of three of the most beautiful, but at the same time most disagreeable-smelling species, were exhibited. But by far the worst, observed Mr. Berkeley, was *Thelephora fœtida*, which he met with three years ago in Aberdeenshire, and it made his room smell worse than the "tomb of all the Capulets," and he could not conceal the odour till he had wrapped the fungus up in twelve envelopes of the thickest brown paper. A beautiful *Maranta* and *Amaryllis* from Mr. Veitch, the Alpines from Messrs. Backhouse, and some other plants, were then briefly mentioned, and, in connection with *Ophrys fucifera*, Darwin's theory of the structure of that and other Orchidaceous plants being adapted to certain insects, through whose agency fertilisation is effected. *Robinia pseud-Acacia Decaisneana* was stated to be a true hybrid, and *Cytisus Adami* was always considered as such by continental authorities, but Mr. Berkeley did not believe that it was a hybrid at all, but that it had arisen from the union of a cell of *Cytisus purpureus* with one of *C. Laburnum*, and that by this cell-grafting the properties of both species were transmitted to the offspring (*C. Adami*). In the collection of fruits, &c., from Egypt was the Chick Pea, *Cicer arietinum*, which was used as a food for horses, and a peculiar narrow-leaved Hemp, used for smoking and the preparation of hashish. In reference to Figs Mr. Berkeley remarked that there was one species, the Sycamore Fig (*Ficus sycamorus*), which grows on the stem of the Sycamore tree, and to which allusion is made in the book of Amos—"I was no prophet, neither was I a prophet's son; but I was a herdsman, and a gatherer of Sycamore fruit." The word, translated gatherer, in our version means scratcher, and unless the Fig were gently scratched or rubbed on the surface it was not edible, and this seems to have been the employment of Amos. Caprification was also effected by a species of *Cynips*, which pierces the Figs, and sometimes by thrusting a straw dipped in oil down the Fig.

Mr. W. Wilson Saunders said that as allusion had been made to the offensive odour of some of the *Arum* family, he would state that when the spathe of *Sauromatum guttatum* first opens, and this offensive odour is exhaled, it rises in temperature. He had found that the temperature of the spathe was 4° or 5° higher than that of the house, and this not on one occasion only, for he had repeated the experiment several times. This observation was not at all new, but it had been doubted whether plants do give out heat.

Mr. Bateman in commencing his observations on the Orchids, directed attention to a plant of *Cœlogyne pandurata* from the Society's garden. This, he said, coming from the burning swamps of Borneo, would never succeed under cool treatment; on the contrary it required a very high temperature. Young, in his "Night Thoughts," had said that Nature never puts on the livery of a mourner, but this plant presented pure black in its flowers. At almost every meeting there had been some new *Phalænopsis*, a name which signified moth-like, Blume having mistaken the flowers of the white species for a string of moths. To Mr. Day belonged the entire merit of flowering for the first time the new *P. sumatrana*, before the meeting, and which had been introduced by Messrs. Low. At present it had only three flowers, but flowers, unlike young ladies, look worst when they come out, and generally improve in after years.

All who have studied art were aware that the grotesque must be sought for in the gothic, and among plants it must be looked for among Orchids. Africa had always had the reputation of being fruitful in monsters, and she had lost none of it in the genus *Angræcum*, which were there most numerous. In connection with the subject of plants having tails, he might mention that W. W. Buller, Esq., of Strete Raleigh, had sent a plant of the Mexican *Uropedium Lindenii* to be named, asking whether it was a new species of *Cypripedium*, having not only tails at each side of the flower, but one in front as well, and Mr. Buller, referring to Darwin, inquired whether these tails were not intended to serve as ladders by which insects might ascend to the flowers; but, added Mr. Bateman, "if I were an insect I would rather trust to the stem of the plant than to these rickety tails." Now, although Orchids having tails were found in the New World, they are not like those of the African Orchids, there the tail was found where it ought to be, and tails, too, of prodigious development, in *Angræcum sesquipedale* 1½ foot long. *Angræcum caudatum* was another beautiful species found in Sierra Leone, and the pestilential swamps of the Niger, but though it had been more than twenty-five years in the country, and was easily flowered, one might almost count the times it had been seen. Another African *Angræcum* boasting of caudal appendages of great length, was one of which he held up a specimen from the herbarium of Kew, sent home by Speke and Grant. This he should call *Grantii*, and he hoped that Englishmen ascending or "doing" the Nile, instead of chipping splinters from the feet of Memnon, or the robes of Isis, would pluck the flowers of *Angræcum Grantii*, which should be its name from thenceforth.

Captain Grant said that had he known that the plant was perfectly new to science, he would have brought more, but they had the greatest difficulty in preserving their specimens on account of the water and insects. It was found on a tree whose boughs were covered with green lichens in a fine undulating country about three degrees north of the equator.

Mr. Bateman again rising exhibited a coloured drawing made by Captain Grant of a plant which either that gentleman or some one else must bring to this country. Fifty years ago there were not many persons who cared about Orchids, and Linneus, after he had gathered together as many as he knew, said, when the world was fully explored there might be 100, and now the genus *Odontoglossum* alone comprised nearly 100 species, one of the most beautiful of which was *O. citrosimum*, as exemplified by the plants shown by Messrs. Jackson, and Mr. Rucker's gardener, Mr. Pilcher. The following history of the plant was given by Mr. Bateman in his "Monogram of *Odontoglossum*":—"Early in the present century two Spaniards, La Llave and Lexarza by name, settled at the Mexican town of Valladolid, in the fertile province of Mechoacan. They were both attached to botany, but the younger of the two, Lexarza, was so attracted by the beauty of the numerous Orchids of the district, that to these he devoted himself with an ardour that would have done honour even to the Lindleys and Reichenbachs of our own day. As the result of his labours a little work—'Orchidianum Opusculum' he modestly styled it—presently made its appearance, wherein about fifty species, all at that time new to science, were described with remarkable accuracy and skill. Among the number there was a plant—*Cuitlauzina pendula* he called it—said to be of surpassing loveliness, and to form an undoubtedly new genus, the distinctive characters of which were minutely given. As time went on and the rage for Orchids developed itself in Europe, a keen desire was naturally felt by cultivators to add so fine a plant to their lists; but although many collectors visited Valladolid, and laid hands on nearly all the other desirable Orchids described by Lexarza, still nothing was heard of the *Cuitlauzina*, and on the cover of the latest number of Dr. Lindley's 'Folia Orchidacea,' its name may be found in the list of genera 'unknown to the author.'" About the same time Mr. Bateman had ventured to say that a man might readily carry as many tufts of it on his arm as would pay his expenses to Mexico and back, and leave him a handsome surplus besides; but happily the challenge was not taken up. Yet all this while *Cuitlauzina pendula* was amongst us, and, indeed, had been an established

favourite for upwards of twenty years. But if so, it may well be asked, How came it to pass that it was never recognised? For a full reply to this very natural inquiry, Mr. Bateman referred to a most ingenious article in "Bonplandia," by the younger Reichenbach, to whom all the credit is due of having solved a great botanical puzzle, and proved to demonstration that the *Cuitlauzina pendula* of Lexarza is none other than the *Odontoglossum citrosimum* of Lindley. This idea had more than once occurred to Mr. Bateman, but the character assigned by Lexarza to the flower-scapes—namely, that it is destitute of bracts could not be reconciled with this view. The *Odontoglossum* which Lexarza had met with had large inflated bracts, whilst in *O. citrosimum* they are very minute, and at long intervals. It now became a question what name the plant was to bear, and however much he was opposed to meddling with established names, he did not see how, in justice to Lexarza, they could do otherwise than adopt the specific name of *pendula*, more especially as the plant was the only one of nearly one hundred *Odontoglossums* that has the flower-stems strictly pendulous. *Odontoglossum pendulum* then let it be to all time to come.

Eighteen new members were elected.

**PELARGONIUM SHOW, June 3rd.**—This was held in the eastern conservatory arcade, where there was a fine bank, both of show and Fancy varieties, 140 feet in length, in addition to which there were collections of stove and greenhouse plants, and numerous boxes of cut Roses. For twelve distinct kinds Mr. J. Fraser, Lea Bridge Road, was first with large finely-grown plants, in splendid bloom, of *Festus*, *Sylph*, *James Lodge*, *Candidate*, at least 3½ feet across, and in fine bloom; *Bracelet*, *Fairest of the Fair*, *Guillaume Severyns*, *Leander*, *Lord Clyde*, a match plant to *Candidate*, and very telling as a scarlet; *Rose Celestial*, *Beadsman*, and *Lillie*. Mr. J. Ward, gardener to F. Wilkins, Esq., Leyton, was second with good well-bloomed plants of *Pline*, a fine orange scarlet, *Osiris*, *Eugénie Legereaux*, a beautiful free-flowering white variety, *Peacock*, *Prince of Hesse*, *Viola*, *Achille*, *Leo*, *The Bride*, *Spotted Gem*, *Picnic*, and *Etna*. For collections of six the same exhibitor was first with *Lord Clyde*, *Madame Furtado*, *Nestor*, *Rose Celestial*, *Bracelet*, and *Patroness*; Mr. Cox, gardener to Capt. Cahill, Southall, was second; and Mr. Donald, gardener to I. Barclay, Esq., Knott's Green, third. Mr. Weir, gardener to Mrs. Hodgson, Hampstead, was also an exhibitor. In the Nurserymen's Class for the same number, Mr. Fraser, was first with *Roseleaf*, very bright in colour, crimson, *Empress Eugénie*, *Sanspareil*, *Excelsior*, *Prince of Prussia*, and *Pizarro*, all of them nicely grown.

Class 4 was for six new kinds of 1864, and here, too, Mr. Fraser was first. They consisted of *John Hoyle*, a finely-formed orange red, marked with crimson, with a dark top, edged with rosy carmine, altogether a very fine flower; *Profusion*, soft, rosy pink, dark blotch in upper petal broadly margined with crimson, white throat, a very pleasing variety; *Rozine*, rose, with a conspicuous white throat, upper petal maroon, edged with crimson; *Coast-guard*, somewhat in the way of *Viola*, but with a much smaller blotch in the upper petals; *Exhibitor*, rose lower petals, white eye, and reddish maroon top; and *Rosy Gem*, rose and crimson, spotted in all the petals.

For a single specimen plant, Mr. Fraser had a first prize for *Desdemona*, very large and beautifully covered with bloom.

Fancy Pelargoniums, though scarcely so large in some cases as we have seen them, were, nevertheless, well grown and in profuse bloom. Foremost came Mr. Fraser, the only competitor in the Nurserymen's Class for nine, with remarkably fine plants of *Delicatum* and *Bridesmaid*; the others, *Lady Craven*, *Cloth of Silver*, *Clara Novello*, *Roi des Fantaisies*, *Hebe*, *Celeste*, and *Multiflora* were also good. For these a first prize was awarded, and in the Amateurs' Class for six, a similar position was taken by Mr. Donald, Knott's Green, with compact well-bloomed plants of *Cloth of Silver*, *Decision* a distinct dark kind, *Lady Craven*, *Delicatum*, *Rosabella*, and *Queen of the Valley*. Mr. Cox, gardener to Capt. Cahill, was second; Mr. Weir third.

For six Fancies of 1864 Mr. Fraser, who was the only competitor, had a first prize for *Ann Page*, *Edgar*, *Mrs. Dorling*, *Mrs. Ford*, all of Mr. Turner's raising; *Princess Alexandra* (Fraser), after *Cloth of Silver*, but with more

colour, and *Blair Athol*. The plants, of course, were small; but not so the fine single specimen of *Delicatum* shown by the same highly successful cultivator, which was upwards of 3 feet across, and a mass of bloom. A seedling Fancy of 1865, called *Mrs. Brewer*, resembling *Princess Alexandra* in colour, and *Faro*, a show kind also of this year—a soft bright rose with a white throat and maroon and crimson top, were also shown by Mr. Fraser; but the gem of the seedlings was *Charmer* from Mr. Bull, scarlet, the eye white, with a violet tinge round it, and two streaks or feathers running up to the scarlet; the upper petal with a dark blotch and broad, painted, crimson edge: this received a first-class certificate. Sparkle, more of a rose colour, but somewhat in the same way, was also a pleasing flower. Mr. Bull also showed several other seedlings, as well as a large collection of new *Zonale Geraniums* and choice *Pelargoniums*.

Of miscellaneous objects Messrs. Lee sent a nice group of stove and greenhouse plants, including a large specimen of *Dicksonia antarctica*, *Dracæna Cooperi* and *indivisa*, *Alocasia metallica*, the graceful *Davallia tenuifolia*, *Oreopanax dactylifolium*, &c., and some flowering plants. From Mr. Bull came also an excellent group, consisting of *Dracænas*, one of which, *D. rubra*, was bearing racemes of violet flowers, *Palms*, a good plant of *Platycoerium alcornice*, the silver-variegated *Peperomia arifolia*, *Gleichenia spelunca*, *Arancharia glauca*, and a new erect-flowered *Gloxinia*, *A. Bonnard*, white, with a rose centre circle, mottled with a magenta tinge. Of *Roses* several fine boxes of cut blooms were shown by Messrs. Lee and Mr. William Paul, to both of whom extra prizes were awarded. Among those from Messrs. Lee were fine blooms of *Mrs. Rivers*, *Victor Verdier*, *Madame C. Wood*, and *Gloire de Dijon*; and of the latter variety a box containing two dozen beautiful blooms was shown by Mr. W. Paul. Another box from the same contained single trusses of the yellow *Noisette Celine Forestier*, each averaging eight blooms and buds, or some half a dozen fully-expanded blooms. In addition these Mr. W. Paul had beautiful examples of *Madame Falcot*, *Madame Villermoz*, *Jean Hardy*, and *Souvenir de la Malmaison*. Mr. Paul also exhibited *Beaton's* new *Geraniums*. Mr. Catleugh, Chelsea, contributed *Lilium auratum*, with blooms about 7 inches across; Mr. Ingram, gardener to Her Majesty, Frogmore, a fine *Smooth Cayenne Pine*, very good *May Duke Cherries*, large and fine *British Queen Strawberries*, and *Prince Arthur*, a conical-fruited sort; and Mr. Miller, gardener to Earl Craven, *Combe Abbey*, *Hybrid Cashmere* and *Combe Abbey Hybrid Melons*.

From Miss Macdaniel, Upper Norwood, came a frame of dried flowers and foliage, with the colours preserved, and which had much the same effect as a painting. Among them were *Pelargoniums*, *Forget-me-not*, *Adiantum*, and golden *Gymnogramma*; and the whole had a very pretty appearance.

## WIREWORMS.

I SEE that one of your correspondents is greatly annoyed by wireworms. As no man in the kingdom has suffered from them more than I have or laboured harder to destroy them, and I trust I now may say I have thoroughly succeeded, it is possible that my experience may help him.

I have taken 140 of these crusty villains out of a single Lettuce, and at one time my land so swarmed with them that not even a Tomato could live. Every known, supposed, problematic, utopian, or maniac remedy was tried. Mustard seed was sown, and they fed upon the root; lime scattered broadcast, and they lived in the lumps; rape-cake drilled in, and they thrived upon it; salt, soot, gas tar, chloride of lime, in which last they lived quite happily in a bottle and made jolly! In a word, I can sooner tell what was not tried than what was.

My firm conviction is that cultivation alone can destroy them. Especially during April and May, when they come up in the imago form, let the surface never rest. Again in the early autumn, when they change their skins and are as soft as a slug, *incumbere tempus aratro*. In a hard winter they burrow to a depth of 2 feet and more; you can do nothing to them then. At the end of February they begin, and we must begin at them.

For three years I could grow nothing small, not even

Strawberries, through them; the trees alone they spared. The sod had been newly broken up, and the ground trenched 2 feet deep. Now I hardly ever see one, except in the newer parts of my ground. If your correspondent has plenty of children, he may have some useful revenge by plunging Potato-slices stuck on a piece of stick, and drawing them every morning. But, after all, the only cure is to harass the villains heartily, and in the third generation discomfit them.—R. D. BLACKMORE, *Teddington*.

### CUCUMBER PLANTS PRODUCING FEMALE BLOSSOMS ONLY.

I HAVE a Cucumber-frame heated by two flues passing under the bed from the back of a kitchen fireplace, and I have maintained a bottom heat at 8 inches below the surface of 80° or 85°; top heat at about 70°. I planted three plants in the bed last year, and had excellent and robust-looking vines, but no fruit; all the flowers were females, and consequently died and damped off. I have tried this year again, and am getting into the same predicament. I have strong healthy plants (*Telegraph*), but on all the three plants the flowers are all females, not a single male flower can be seen. I water every second or third day with tepid soft water, and then give a good soaking. I have raised excellent fruit in dung-frames, but I must say now that I am puzzled.—C. W. W.

[You had better have an open chamber, or a rough one of clinkers, over your flues, with means of pouring water, not on the flues, but on the clinkers between and round them. However, your case rather surprises us. Try what thinning out freely your great show of female flowers will do. Cucumbers will swell freely enough that never were influenced by the male flower, but of course such fruit will have no seed capable of germination. Thin the fruit, and secure moisture at the bottom without passing the moisture through the soil. A small drain-pipe set on end will enable you to do that. Let us know the result.]

### MY PLANTS,

AND HOW AND WHERE I FOUND THEM.—No. 3.

“THERE one can inhale pure breezes, a rural walk, and

‘Breast the keen air, and carol as he goes,’

should he have any propensity to indulge in sweet sounds. No innovation on his purse—no mendicant to interrupt his quiet meditations with vescatory importunity. He may pick Buttercups under any hedge, and no policeman order him to ‘move on;’ and in his solitary ramblings he has nothing to dread but a gipsy fortune-teller and a sticking cow.”

Thus writeth Dionysius O’Dogherty, Esq., of that spot in our fair island denominated Highgate. Much more applicable do I deem his rhapsody to the lovely walk adown which (escorted in my mind’s eye by my companionable reader), I purpose travelling this summer evening. In a dip in the valley we are sure to find the picturesque group around the gipsy camp, for there a stream of water runs near at hand, leaping bright and clear over the marble-like pebbles common to this neighbourhood. There is the necessary shade and feed for these dark-eyed wanderers, and, above all, a good supply of game for the pot which is now hanging over the fire, and which, if I mistake not, would find it difficult to escape the quick eye and fleet feet of the lurcher who is keeping guard over the vans. We have Pine woods to our right and left, a vast moorland before us, and a long tortuous road to pursue, set on either side with Ferns, Grasses, and Heather. The distant moor is purple with the latter, richly lit up with the farewell rays of the departing sun, which, lover-like, keeps his fondest and yet saddened look for the moment of bidding his adieu.

It was on an evening like this that my husband and myself drove quietly along the road from Upper Tean to Great Yate. Never can I forget the impression its wild grandeur made upon me. It reminds one of times long, long past, when the Romans held sway in this sea-girt island of ours. It might have been untouched from their time until now, so dark are the Pine woods, so wild and uncultivated the moorland—so bleak, so primitive, so quiet does every-

thing appear. A few farms are dotted here and there; but the attempt seems to have been almost ineffectual to reduce the natural boldness and magnificence of God’s first work to the so-called refined ideas of this present generation. Over the moorland still roams the black and grey rabbit; and the grouse, moorcock, and partridge still hold their evening confabulations. Here we come upon the *Triodia decumbens*, which with its purple spikelets looks so completely a Grass suited to the choice tastes of the birds which frequent these waste lands. Around us are specimens of the *Aira flexuosa*, *A. præcox*, *Nardus stricta*, several kinds of *Festuca* and *Bromus*, also the *Avena pubescens* or Downy Oat Grass. Beneath our feet is the Cowberry or red Whortleberry, of which the flower is flesh-coloured, and the berries red, acid, and rather bitter. Like the Cranberry and Bilberry, it is used in tarts, and made into preserves by the country people. It is little inferior to the former when cooked. In dense patches grows the Bilberry, with its smooth dark green leaves and bluish black fruit, which is much sought after by the children of the poor, who gather the berries for sale, making in an unfruitful season as much as 10d. per quart. Cranberries realise a larger sum, not because they are less plentiful in many parts of Staffordshire, but because, the gatherers say, they are so small and necessarily cost them more time and labour. This fruit is little used amongst the labouring classes, as being an extravagance with regard to the quantity of sugar which it requires to make it palatable. Whilst strolling amongst the Ling and Heath I may mention that a white variety of the former is found at Frogghall, and I have also gathered a few sprays upon a bank at Free Hay. I have been told that the *Arbutus uva-ursi*, or Red Bearberry, is to be met with upon some of these rocky heaths, but I have unsuccessfully sought for it.

Having collected the above information with regard to the value of the relative berries which grew on the moor, we continued our ride through Great Yate, or rather sometimes driving and sometimes alighting from our dogcart, and trusting the animal thereto attached to his good sense of propriety to follow us or await our pleasure, we well scanned the banks and ditches around us. The *Anthoxanthum odoratum* had seen its best days, and was looking “seedy” and *de trop* amongst its fresh and newly clad neighbours, the *Festuca ovina*, *F. duriuscula*, and *F. pratensis*, the *Avena pubescens*, the *Lolium perenne*, *Briza media*, and *Aira flexuosa*. Leaving the common and roadside grass, we come to the ditches between it and the moor. Here we have the *Aspidium spinulosum* with several varieties, the *Filix-mas*, *Blechnum spicant*, and last but not least the Lady Fern in its many stages of growth and characters. In some of the banks it is most luxuriant, particularly above a wet ditch at the foot of the bank where they grew, and where the fronds were of a great length.

“Where the copsewood is the greenest,  
Where the fountain glistens sheenest,  
Where the morning dew lies longest,  
There the Lady Fern grows strongest.”

Proceeding on our journey we reached the small church of St. Giles, in the pleasant village of Croxden. With eager eyes I scanned the building; and there, above the battlements, most comfortably ensconced, and apparently in its luxuriance alike defying wind and weather, were several sturdy plants of the *Ruta muraria*. I took the reins, and my driver gallantly and kindly ascended to the devoted spot, and with his pocket-knife carefully detached two or three splendid bunches. I transferred it subsequently to my fernery in our little garden, but either owing to unsuitableness of soil or situation it never flourished so well as it did in its elevated home on the old church.

At a short distance from the church is the fine ruin of Croxden Abbey, where we were told the heart of King John was buried. This, however, did not interest me so much as the discovery of plants of the *Geranium lucidum*, or Shining Cranesbill. The *Parietaria officinalis* (Wall Pellitory), the *Sedum reflexum* (Crooked Stonecrop), and *S. telephium*, or Orpine, grow upon different spots of this home of the jolly old friars. Just as we were exploring the building, one of those smart and heavy summer showers which so refresh the thirsty and panting earth at this time of the year came on, and we took shelter in the dogcart under the friendly protection of the old abbey. We had time to think of the

beating hearts which once dwelt there, and made the walls echo with their prayers and masses—those hearts which now lie buried and still beneath its cloisters. Was it not a small world within itself? Were there not as many passions throbbing in those breasts as in those of the heretics without the walls? Doubtless many an earnest Christian there lies awaiting the last awakening by the Judge of All. Of whatever creed, one there standing patiently might say—

"Ashes are on my head, and on my lips  
Sackcloth, and in my breast a heaviness  
And weariness of life, that makes me ready  
To say to the dead abbots under us,  
'Make room for me!'"

Then we thought of "Friar Claus," who had charge of the convent cellar, and who so gloriously revelled in its wines; of "Friars Paul" and "Cuthbert," and of the revels in the refectory; and we came to the sapient conclusion that there was as much true religion in this outer world as was fostered within those ancient walls.

The shower ceased, and the charm of our drive was increased by the coolness of the atmosphere, and the sombre tone which our thoughts had taken from our stroll about the old abbey and its tombs. The Ferns and Grasses, dried and parched when we before passed them, now gratefully bowed beneath the heavy load of wet; the birds were singing in

an under tone their evening song; and the lark, vociferating its gratitude, sank down to its bed in the heather.

"The partricks down the rushy holm  
Set up their e'ning ca'."

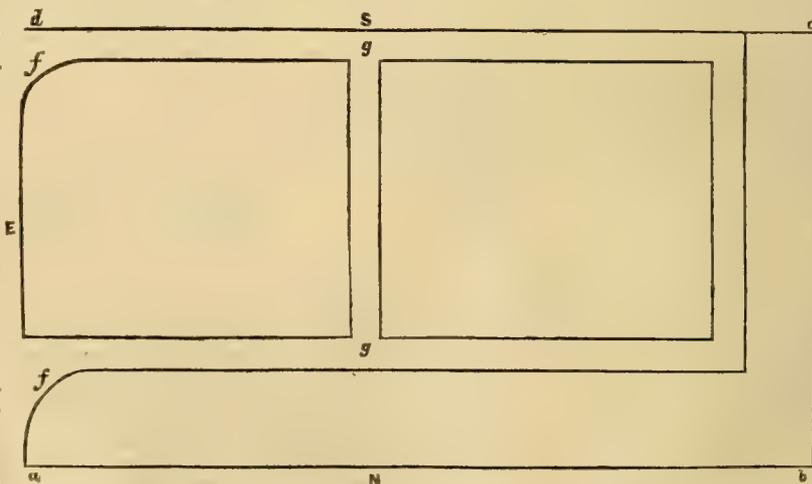

The Roses fould their silken leaves;  
The Foxglove shuts its bell;  
The Honeysuckle and the Birk  
Spread fragrance through the dell."

The Digitalis or Foxglove, which is so plentiful in this county, and which with the green fronds of the Ferns form such beautiful groups upon our banks, must not be forgotten; nor yet the Oxalis acetosella, the charming Wood Sorrel, with its bright green leaflets and delicately veined flowers adorning each hedgerow. The simplicity and elegance of this lovely gem, sitting in modest beauty upon its couch of moss, always reminds me of the unobtrusive yet quiet self-repose of the well-bred lady. A month or six weeks later in its birth, and almost equally graceful, the Wood Strawberry covers the same localities. Its white blossom and pendant red fruit are well known to the lovers of the beautiful as well as to the botanist. I once found a large kind of Strawberry near Leigh, with leaves as fine as the cultivated plant, and fruit equally luxuriant. I supposed it might be the *Fragaria elatior*, as it was too robust in its habit for the *F. vesca*.—ALICE.

KITCHEN GARDENING.

In writing on the above subject I feel that the first thing to be taken into consideration is the aspect of the garden and the nature of the soil; but generally speaking, when an amateur or gardener takes a place, there is the kitchen garden, and there it must remain. In nine cases out of ten the garden will be found to be very small in comparison with the wants of the establishment; but there is one advantage in a limited extent of ground, and that is, you may change the character of it by experiments that would be hopeless on a larger scale.

The generality of kitchen gardens in the suburbs of towns are mostly sufficiently sheltered by buildings or trees, but if it can be managed it is best to have the kitchen garden open to the south and south-west, as the extreme in this case, as in all others, is to be avoided. It is very seldom that a man enjoys the rare privilege of making his kitchen garden how and where he pleases, but as it is sometimes the case, perhaps it will be best to give a rough sketch of that at present under my charge, as I consider it to be as good as any I have seen—that is, for a garden of not more than half an acre in extent. It is in the form of a parallelogram, the letters

N., E., S., W. representing the points of the compass. *a b* is a Peach-wall some 12 feet in height, and running parallel from east to west; *b c*, a low fence from north to south; *c d*, an evergreen hedge about 6 feet high; *a d* is a Yew hedge 8 feet high; *f f*, entrances from the forcing-ground; *g g*, the walks. The interior arrangements, of course, must be according to the taste or requirements of the proprietor.

Now, as to the nature of the soil. Very few are so fortunate as to possess the sort of ground most to be preferred for kitchen-garden purposes; but, on the other hand, gardening is more independent of external circumstances than

farming; or, in other words, few gardens are in such a hopeless state or on such ungrateful soil but that something may be done to fertilise and improve them. For instance: light warm soils are naturally early, and in hot dry seasons like the last too much so, yet this evil may be guarded against by the admixture of good heavy dressings of well-rotted manure every time the ground is dug, such as the bottom of the manure-heap in the farmyard, and the more moisture that can be carried on and dug in with it the better. I am well aware, and I daresay there are too many who could bear testimony, that in many instances every barrowful of manure is begrudged to the garden, and looked upon almost as a robbery of the farm or paddock; but this ought not to be the case where the gardener is expected to

have his crops as early and productive as the market gardeners, who load their land with such a variety and at the same time such enormous dressings of manure, that if the weather is at all propitious their crops must succeed. In fact, it is of the utmost importance to them that they should do so, and they are well aware that if they do not apply such fertilising elements as their experience and

judgment combined prompt them to do, they would not be so successful as many of them are. It is a well-known fact that many of them, by untiring industry and foresight, support a large family on a plot of ground that in its original state would scarcely produce enough to support a cow. I think that if this manure question were more considered the gardener would not so often be found fault with for being behind his neighbours, or he would have such materials placed at his command that he would be enabled to give satisfaction to his employer and do credit to himself.—BURNTWOOD, P. D.

(To be continued.)

## FIGS FALLING PREMATURELY.

A Fig tree, the White Carrington, against the back wall of a vinery, planted about four years, has had good crops during the past three years, but the Figs, after arriving at the size of a large marble, have in each year turned yellow, and eventually dropped off unmaturing. The tree is confined to its own border of 2 or 3 feet square, the soil being well mixed with broken brick and lime rubbish, and has been well watered, but all to no purpose. The same has also happened to Figs in pots.—W. H. R.

[It is not confinement of the roots that is the cause of the Figs dropping; stagnant moisture will do it, and dryness of the soil will do it, and either will tell prejudicially most when the Figs, like yours, are about half swelled. From the time Figs are the size of large Peas the soil should never be dry, and the moisture should never be stagnant. There are two ideas more: first, the Fig tree is on the back wall of a vinery. Do you give it enough light? If not, the young fruit will be apt to fall, from the immaturity of the wood last season. Again: Is the tree very luxuriant? Sometimes when that is the case the very free flow of sap throws the fruit off, and we have in such a case helped them by cutting rings of bark off the shoots one-eighth of an inch in width. We think if the wood have enough light, and the roots are confined, that something in the watering may be the cause. A year or two ago we had a little pot half plunged in the soil, and most of the fruit dropped. On examining the pot we found the drainage was stopped, and the lower half of the pot was in a morass. Stagnant water at any time is their abomination.]

## GLOIRE DE DIJON ROSE ON A BOURSULT STOCK.

I FEEL it a sort of duty to report to you the very successful result of an experiment tried upon a Gloire de Dijon Rose budded on a Boursault stock, the stock being a bad bloomer, although it had the advantage of a southern aspect outside a lofty old greenhouse with low windows. To turn it to ornament we planned many things, and at last resolved to bud it and treat it like a Vine, leaving the root outside and pulling the stem in. We nailed the budded branches upon the end wall inside, and the very first season had about seventy Roses from the middle of April on to May; but this second season the produce has been quite marvellous. It began to bloom in the last week of April, and in the course of ten days, or within the fortnight to about the 12th of May, we had upwards of two hundred splendid full-blown Roses from the plant. The only peculiarity in the treatment besides the Vine system was the quality of manure with which the roots were bountifully supplied—namely, a barrowful of old stuff collected from a shed in a field, the resort of horses, cows, and sheep for shelter.—AN AMATEUR ROSE-GROWER, *Belgard, Tallaght, County Dublin.*

## MR. JOHN WATERER'S AMERICAN PLANTS.

THE Knap Hill plants at the Regent's Park are now at their best, and a magnificent spectacle do they present. An area of about 100 yards in length and the same in breadth, with an undulating surface and winding walks, is covered in with canvass, and planted with many hundreds of Rhododendrons and Azaleas in gorgeous bloom, and especially striking is the effect when viewed from an elevated bank which commands a view of the whole. The arrangement too is most excellent for effect, the colours being judiciously intermixed, and advantage taken of a Plane, Laburnum, and some other trees which exist in the ground, as well as of the foliage of the Rhododendrons themselves, to relieve the brilliant rose and crimson flowers by green leaves; and yellow and orange Azaleas introduced here and there serve to give a variety of form and colour which would not otherwise exist.

Among the large plants there is one of Lady Eleanor Cathcart planted on a mound—a standard having a head probably not less than 25 feet in circumference; of Roseum elegans there is one little less in size, and many more individual plants might be cited. Among scarlet and crimson-flowered varieties the finest are John Waterer,

which is very brilliant in colour, a large trusser, and one of the most useful for general purposes, Mrs. John Waterer, a very fine rosy crimson, Valasques, Admiration, Regificum, and Giorgione. Iago is a good rosy purple, and Joseph Whitworth, a new large-flowered dark purplish lake. Among whites the best are Album grandiflorum, of which there are many fine plants, La Vivandière, Minnie, a free-blooming blush white, with a large blotch of yellow spots, and Lady Godiva. Butlerianum, white tinged with pink, is also good. To the new kinds (vol. 6, page 430)—viz., Mrs. John Penn, Lady Emily Peel, Princess Mary of Cambridge, &c, have to be added Sidney Herbert, a large bright carmine flower, Earl of Shannon, a showy dark crimson, of great substance, Consolator, and Warrior, bright scarlet crimson, and Sir Robert Peel, a brilliant rosy crimson with strongly-marked dark spots, besides which there are this year many seedlings as yet unnamed. One of these is a very striking variety, having a very pale pink or white centre, edged with the brightest rose. Another is very remarkable for the great size of its blooms. The exhibition will continue for several days, but we would advise all who intend visiting it to go at once.

## FERN HABITS.

HAVING been for some years much interested in the management of a small Fern-house, some curious facts have come under my observation which, I think, may not make an uninteresting article in your Journal.

I have a plant of the Killarney Fern (*Trichomanes radicans*), growing under a glass shade in a large porous saucer, set in one not porous, with water under it, but raised so that the bottom of the porous saucer does not quite touch the top of the water. About it were put several stones, and among them a piece of brain coral, about 3 inches in diameter, which had previously been in a case with *Asplenium marinum*. At the top of the glass shade is a hole for ventilation, through which Ferns that hang in baskets above it often seed themselves. After some time the piece of brain coral became covered with young vegetation, which, about two years ago, developed into plants of *Asplenium capillus-Veneris*, *A. marinum*, and *A. trichomanes*. They grew fast, though no soil was on the coral except what might accidentally have dropped into the interstices. The *capillus-Veneris* soon became so large as to interfere with the Killarney Fern, so, last year, I moved them into a smaller case by themselves, filled the bottom of it with water, and put a large piece of perfectly clean white coral to stand in the middle of the water, like an island, with the bit of brain coral and Ferns on the top of it. Soon a slight green vegetation appeared on the lower piece of coral stretching like a cobweb from point to point; the little roots from the Ferns have gradually crept down to it, and they have completely fastened the two pieces of coral together, and are forming a soil on the lower piece, which promises shortly to be covered also with plants to the level of the water. It is a curious instance of Ferns forming a soil for themselves unassisted by anything but nature.

The Killarney Fern grew very lazily for some years till the spring of 1854, when some petrified moss was put into the case near the roots above the soil, and immediately they touched it they began to push themselves above the soil and on to the petrified moss, and grew upon it so vigorously that it has completely filled the case, and is going to be moved into a larger one, when I intend putting the coral and Ferns into the one it is now in, with more coral and water under, but no soil, so that I can ascertain how large they will grow on the porous substance with only moisture to nourish them.—E. B.

## ENTOMOLOGICAL SOCIETY'S MEETING.

THE May meeting of this Society was held on the 1st inst., the chair being occupied, in the absence abroad of the President, by H. T. Stainton, Esq., F.L.S., Vice-President.

The Secretary read an article recently published by the Society of Arts on a new American Silkworm, or rather on the successful attempts recently made to unwind the silk from the cocoons of *Saturnia Polyphemus* in North America,

the thread of which possesses considerable lustre, and a single cocoon contains as many as 500 yards of thread. As much as seven waggonloads of the cocoons had been sent to the Technological meeting lately held at Boston, U.S.

Mr. Stevens exhibited a Shield Beetle (*Cassida* sp.), found alive in London, which had evidently escaped from a newly-opened case of Orchids, but which had unfortunately died a few hours previous to the meeting. When alive it presented a brilliant metallic appearance, which faded after death; and some discussion took place as to the insufficiency of technical descriptions made from museum specimens of such species, which were of course quite at variance with the appearance of the living insect.

Mr. Stainton exhibited a nest of hairless caterpillars of some species of Moth, found near Marlborough suspended from a Beech tree by silken threads.

Mr. F. Smith read a letter recently received from Dr. T. C. Jordan, dated Lahore, 16th March last, in which the writer announced that he had discovered that the wingless Ants of the genus *Typhlopone* of Westwood were the true workers of the species, of which the strange insects known under the generic name of *Dorylus* were the winged males. The females of these singular insects have yet to be discovered.

An extract was read from Mr. Waterton's "Wanderings in South America," from which it appeared that the larvæ of the Chigoe or *Pulex penetrans* (when hatched from the mass of eggs contained within the enormously distended body of the female), burrowed into the flesh of the toes in the vicinity of the wound caused by the entrance of the female insect into the flesh.

A discussion on the luminous powers of the winged Fire-flies of the family *Lampyridæ* took place, the Rev. Hamlet Clark having observed that these insects in South America emitted their flashes simultaneously, so that there was a regular intermission of the light, the insects apparently flashing contemporaneously and in concert. Mr. Bates in the Amazons, and Mr. W. Wilson Saunders in India, had not observed any such regularity in the emission of the light, which, on the contrary, appeared to be quite irregular and independent. Mr. H. Clark also called attention to the ravages of Woodlice in a garden, where a short time ago a quantity of peat had been laid down.

Mr. Stainton read a notice of a memoir published in the new part of the "Proceedings of the Philadelphia Entomological Society," in which Mr. B. Walsh gave an account of the different species of insects found in galls upon Willow trees in North America, amongst which were as many as seven different species of Lepidopterous insects—namely, three *Tineidæ* belonging to the genus *Gelechia*, and four *Tortricidæ*, the larvæ of these Moths feeding upon the substance of the galls, although not the original makers of them. A variety of Coleoptera, Hymenoptera, and especially Diptera, of the genus *Cecidomyia*, were also found in the galls, of which there were not fewer than ten different species.

The Rev. H. Clark exhibited a collection of plant-feeding Beetles captured by M. Du Boulay in the district of Champion Bay, West Australia, among which was a remarkable *Eumolpid*, which has the power of leaping by means of the middle pair of legs, which are thickened. He described a number of these insects, preceded by some observations directed against descriptions of isolated species, which cause so much trouble to the student.

Mr. F. Smith read descriptions of some new exotic Hymenoptera of various families, including three species of *Paragia*, a remarkable genus of Wasps, and a new genus of Bees having antennæ clubbed like those of a Butterfly.

—Mr. Bates read a paper describing four additional new species of South American Beetles belonging to the genus *Agra*, from the collection of W. Wilson Saunders, Esq.

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

Now is a good time to carry on a vigorous crusade against weeds, the hoe ought never to be at rest in well-cultivated gardens till they are all destroyed. *Basil* and *Marjoram* sown in beds to be thinned out to about 6 inches from plant to plant. *Beans*, make another sowing, top the most forward crop if not

yet done. *Broccoli*, to have the Cape varieties fine the seed to be sown where the plants are to remain, deep drills to be drawn, and two or three seeds dropped in at the distance of 2½ feet apart, slightly cover the seed, and keep watered should dry weather occur. When the young plants come up thin to one plant at the distance named. *Cabbage*, this is a good time to sow a little seed for autumn produce, any of the small sorts to be preferred for this sowing. *Cauliflowers*, plant out some of the first sowing in the open ground. A small quantity planted from two or three sowings will keep up a succession better than the small stunted plants of very early sowings. *Cucumbers*, peg down the plants on the ridges as they advance in growth, and when the hand-glass will no longer contain them set them on three bricks placed edgewise, or on crotch sticks; when they require water give it them milk-warm in the day. *Onions*, after thinning loosen the soil between the rows, and if the weather is dry give them a thorough watering. The thinnings of the beds may be planted out, but must, if the weather prove dry, be watered every evening until they take fresh root-hold. This must be carefully attended to, as the roots will be very near the surface. *Peas*, the last sowing of Knight's Dwarf Marrow should now be made, as it is longer in coming into bearing than any other. Continue to earth up and stick the advancing crops. If the pods of the early crops do not fill well give a good root-soaking, which will be sufficient for them while they last. *Radishes*, make another sowing of the various sorts to succeed those sown in the middle of last month. *Savoys*, plant out some of the early sowing. The dwarf sorts may be planted about 1½ foot apart in the row, the rows to be 2 feet from each other; the larger sorts should be 2 feet in the row, and the rows 2½ feet apart. *Tomatoes*, as they are usually planted under a south wall, where they receive but little benefit from a passing shower, they should be occasionally watered, and kept mulched with short litter. Nail and stop the shoots as they advance in growth. Continue to thin the crops while they are small.

### FRUIT GARDEN.

The ravages of caterpillars upon Apple trees about the suburbs of London are truly awful. Among the practices adopted by gardeners of the old school was making a fire to the windward of the orchard, and allowing the smoke to circulate in clouds amongst the trees. Although we were inclined in our younger days to smile at the idea, nevertheless we have lately adopted the practice, and can strongly recommend it, as thousands upon thousands of caterpillars have been dislodged from the trees and fallen to the ground suffocated by the smoke and heat. The shoots of Cherry trees infested with the black fly should be dipped in tobacco water immediately the pest is detected.

### FLOWER GARDEN.

The newly-planted things will require constant watching, as under the best management failures will sometimes occur; these should be made good, and the tying and staking of everything requiring support should on no account be delayed. Where an immediate display is not wanted, the buds may be pinched off for a week or two to encourage the plants to cover the ground. Creepers against walls and trellises should be constantly gone over to tie or nail them in. Standard and pillar Roses should likewise be looked over to see that they are properly secured to their stakes. Take every means to eradicate all the broad-leaved plants and coarse-growing grasses from the lawn, which they much disfigure, and keep it closely cut with the scythe or machine. Strong shoots of *Chrysanthemums* may soon be layered to produce dwarf compact bushes. Take the first opportunity after a shower of rolling and regulating walks. *Hollyhocks* should now be staked, tied, and attended to as they advance in growth. Be sure that plants growing in vases, baskets, &c., are properly attended to and thoroughly watered in the evenings of hot days. The rosarium should likewise have all the attention that can be spared at this busy season; remove all suckers, and keep a sharp look out after insects. The Rose has many enemies, from the earwig to the aphid, use all means at hand to destroy these; though nothing comes up to hand-picking for the destruction of grubs and beetles, it is a tiresome method, yet it is the only one to which recourse can be had with permanent advantage.

## GREENHOUSE AND CONSERVATORY.

Hardenbergias, Kennedias, &c., may be slightly cut back after blooming to induce a new growth. Water to be given liberally to plants in the border of the conservatory, excepting, perhaps, plants very recently planted; shade daily when necessary, and give air in proportion to the state of the external atmosphere. The stock of Balsams and other annuals grown for filling the vacant places in the greenhouse, &c., should be encouraged by frequent shifts, keep them in bottom heat and near the glass; pick off the early-formed bloom-buds, as the plants should attain a considerable size before being allowed to bloom. Continue to train Kalosantes neatly, and water occasionally with liquid manure. Specimen Scarlet Geraniums should likewise have liberal encouragement to grow them on. Common and Fancy Pelargoniums, for late bloom, will thrive better in a somewhat shady situation. Fuchsias, if not in their blooming pots, should be potted forthwith. Train in the desired form, and pinch back weak and straggling shoots. The glass to be taken off Japan Lilies, Gladioli, &c., unless very early blooms are desired. Keep a portion in the shade of a north wall for a succession of bloom. The principal part of the greenhouse plants may now be safely taken out of doors. Select a shady situation open to the east and protected from high winds. Take care that the plants stand on a bottom carefully prepared to exclude worms from the pots.

## STOVE.

Continue to shift all such plants as require it. This is a good time to pot Peristeria, Phajus, Cymbidium, and all other Orchids that are starting into growth. The best time for shifting Saccolabiums, Vandas, Camarotis, Aërides, and all plants of similar habit, is as soon as they have done blooming. In giving them new baskets, afford plenty of room and good open material to grow in.—W. KEANE.

## DOINGS OF THE LAST WEEK.

## KITCHEN GARDEN.

The chief work has been trenching Broccoli ground for Peas, Turnips, late Carrots, Dwarf Kidney Beans, &c, the latter requiring rich soil to produce heavy succulent crops. Watered Cauliflowers, and staked successional Peas. We have now no doubt that our early Sebastopol Pea, which has done us good service, is identical with Dillistone's Early, about the earliest we have met with, but no great bearer. Cleared off our Tom Thumbs from orchard-house, where they proved themselves useful. Took up a bank of Scotch Cabbaging Kale, which was just running to bloom, as Cabbages were plentiful. To avoid the trouble of wheeling out, and as we are scarce of manure, will trench them into the soil. This may always be done with all sorts of large weeds except seed weeds, which should never be buried in the ground. In fact, it is bad policy and in opposition to all economics ever to allow a weed to arrive at the seeding state. When cut up when an inch in height, the sun does all that is then necessary for their destruction. Groundsel cut up when knotting for bloom in dull weather, contains enough of moist nourishment in it to perfect and sow its seeds. It never can be got rid of in a garden, if it is allowed to arrive at the seeding state. The other Sunday we noticed in a cottage garden, untenanted, one huge heavy crop of Groundsel just seeding. Self-interest should have led neighbouring cottagers to clear, and clean, and crop the garden, if they had been permitted, as the seeds will be sure to be wafted to their ground. In the garden itself the seeds will be so numerous that twenty years will scarcely see the last of the produce of this year's seeding. The Dutch hoe is the best tool for all places where it can be used. Cut up the weeds before they become large, and let the sun dispose of them. Where nicety is required the hoe may be pulled backwards to make all smooth. A rake for such purposes is worse than useless. The raking of weeds always shows bad management, or deficiency of labour power, and the very act of raking increases the evil, from the time it occupies. As for flower-beds, we would as soon see a donkey trampling among them as a rake. It used to be the fashion to rake flower-beds as level and pretty well as hard as a piece of pavement. We would rather have them loose, and then a back stroke with the rake can do

everything in the way of neatness. Thinned most of our Onions, Carrots, Parsnips, &c., which have come up very thick, and sowed Salsafy and Scorzonera to prevent it running. Sowed more of Dwarf Kidney Beans, and the last of Broad Beans, as they seldom do much good if sown later. Watered Cauliflower with sewage water, and earthed-up some later Potatoes. The Ash-leaved that were protected at first with glass have done very well. Taken all-in-all, we find nothing, that for early purposes, beats the Ash-leaved. In limited room out of doors, the small tops are a great recommendation.

## FRUIT GARDEN.

For want of time we have not yet turned out many of our forced Strawberries, but will do so as soon as possible, and would like to give a good watering to those out of doors, and then cover the spaces between with long litter from the stables. Clean straw, where it can be obtained, is best; but a good shower of rain will render the litter clean before the Strawberries are ripe. Long grass is also good, as it becomes hay before the Strawberries rest upon it. Short grass, also, is not to be despised where nothing else can be had; but it brings lots of weeds, and in heavy rains it is knocked into the interstices of the fruit. All sorts of tiles are apt, from scorching, to do as much harm as good. Where none of the above coverings can be easily obtained, no better plan can be adopted than running a string on each side of the row, supported by stout little rough sticks. We saw some fine Strawberries last year so dirtied and smeared that they had to be washed before using them. What a fine taste they must have had. It would have shown more of the "vaunted-genteel" to have made no attempt at Strawberries, instead of breaking down at the point of protecting them from soil and mud. We are now thinning them out of houses and pits, and as yet we have not been troubled with spider, or anything else. Early in the season we saw some green fly on a few flower-stalks, but the finger and thumb did for them, and we have seen none since. We have more faith in a quick eye and nimble fingers than in all washings and smokings put together. If this should catch the eye of Mr. Donaldson, we should like to hear how his very strong plants succeeded last season. Some half a dozen of failures, we have no doubt, were owing to luxuriant growth, late potting, and large pots. He seemed to be taking extra care that his plants should be well matured, and of course that secured, extra strength should yield extra crops.

Went over Apricots and Peaches out of doors, thinning shoots and fruit, and giving them a good lashing with clear soot water from the garden engine, as much in precaution as otherwise. The nice rain alluded to last week broke huge boughs from forest trees, and also broke down Gooseberry and Currant bushes heavily laden. Some that had four stakes and rough wooden hoop round them were safe enough. We never knew rain hang so heavily on trees for such a short continuance. The high winds of Monday also did damage to trees and bushes. Strawberries in the orchard-house are swelling fast. Will top-dress with horse-droppings and soil the fruit trees in pots, as that will not only give nourishment, but will also, as mulching, save waterings. We did not care about doing this sooner, as we wished the soil in the pots to be well heated. Sent thinnings of fruit of Peaches for tarts. Can find no use of that kind for the extra supply of Nectarines. When bruised and soaked in hot water they make a strong tea that no insects like, and when used fresh the scent is very pleasant, but very unpleasant when kept for several days. Tied-in shoots against wall, and kept nipping, with the finger and thumb, the points of shoots of trees in pots. Caterpillars have needed hunting after, especially on Plums. They show where they nestle by the rolled-up leaf. Nothing but crushing will destroy these pests, as the curled-up leaf defends them from all attack, and what would make the leaves unpalatable would also be apt to injure them. Noticed one Cherry tree with scalded and blotched leaves, owing to scars in the glass, and daubed a little paint on the spots. They were rubbed over with soft putty last season, but it had come away, and hence the burning. Three years ago the bottom of a tree was thus blotched day after day, and at last we discovered a scar not larger than the lines of ordinary writing, but it did all the mischief. We advised a lady lately, who had been recommended to have 1½ d. a-foot

glass for an orchard-house, not to grudge a few shillings more for 100 feet. The cheaper the glass the more likely, as a rule, will you be to have spots, that will concentrate the sun's rays, and scorch and burn. We hope we shall learn much more on the glass question.

We may here broadly notice a simple fact, that in connection with ventilation some people with orchard-houses seem slow to comprehend. Have a short span-roofed house—say from 40 to 60 feet, with ventilation at the apex at each end, and ventilation at each side, and you need not trouble much about ventilation at the roof. For a late house, and a long length, you need not trouble at all. Have a lean-to house against a wall and no top ventilation, and we would not augur much for success in anything except breeding red spider enough to supply a stock for a continent. In the span-roof, with ventilation at each side, the heated air will not accumulate much at the apex, as this thorough current prevents all that. Mr. Rivers thoroughly understands all this. But in a lean-to, without ventilation at the apex, there is no regular current, and the hottest and moistest air will be found at the narrow apex of the roof. For a small house some 20 feet in length, air at the ends under the apex would be sufficient; but for 30 feet we would require two openings in the middle as well. For a long house of from 60 to 100 feet, every other square should open, so as to give from 9 to 12 inches all the way. Two ideas more—early air-giving is even more important than the quantity. We have known houses spoilt because they were shut until nine o'clock on a sunny morning. And, again: even as to air there may be too much of a good thing, and large openings in front to admit cold frosty air will do more harm than good. A gentleman lately told us that a great practitioner seemed to throw all his ventilators open without ceremony even in cold weather. That we presume would be when the trees were in a condition that they could not suffer. We know for a fact that the same cultivator hangs thick woollen netting over the ventilating openings in severe weather, to moderate the force of the cold air, and to secure its being mollified before reaching the trees when in a tender state. Nothing is more important than air-giving to everything under glass, and few things are more neglected, or become mere work of routine. In our boyish days we have seen a man leave his breakfast more than once to add to, or reduce air. Now too often the air given in the morning remains unchanged until it is taken away at night. There is a medium between the two extremes, and the thermometers and the clouds should be closely watched to prevent all sudden changes. Some time ago we directed particular attention to this subject.

ORNAMENTAL DEPARTMENT.

Besides tying and potting lots of plants for summer and autumn, and watering more freely than we would wish for our supply of water, the chief work has been rolling, mowing, and machining lawn, and getting out lots of bedding plants. The weather on the whole has been dry for such work, and the wind on Monday the 29th was very trying to fresh-planted things; but the first-turned-out are now taking hold and will look after themselves. We do not care about moving the surface much after planting as yet, in order that the ground may become warm, and then the rooting process will proceed more rapidly. We have stirred the ground among Calceolarias, and as soon as possible we shall mulch them.—R. F.

LILIIUM AURATUM.—Mr. Stevens announces a sale of established plants of the charming *Lilium auratum*, on Tuesday next, the 13th inst. We believe that upwards of fifty of them are expected to be in bloom on the day of sale, a circumstance which will render the well-known auction-room unusually attractive, and quite a flower show on the occasion.

COVENT GARDEN MARKET.—JUNE 3.

The market continues to be abundantly supplied with all kinds of produce in season. Pines are sufficient for the demand and very good; Grapes, I know, are plentiful and good. Peaches and Nectarines have improved in quantity and quality, and a few Strawberries from the open ground have made their appearance. Peas are now brought in large quantities, and sell at about 6s. per bushel. Of Cucumbers there are large importations from Holland. New Potatoes from Lisbon are to be had of excellent quality, at from 2s. to 4s. per lb.

TO CORRESPONDENTS.

SEEDLING PANSIES (*L. F. F.*).—Many of your seedlings are showy flowers, but too coarse and rough. The petals want substance. They are not equal to the Pansies of the present day. The very dark one was a promising flower, as well as that with a white ground and dark violet centre.

DEVONIENSIS ROSE.—We have received from Mr. S. J. Pavitt, Rose Cottage, Bathwick, Bath, some trusses of this Rose worked last May. They are about the most vigorous, highly-perfumed specimens that ever came under our notice.

ANTS (*A Voice from the Glen*).—You are quite mistaken in concluding that ants destroy bulbs and fibrous roots. They may be driven away by watering their haunts with the ammoniacal liquor from gas works.

BOTANICAL WORK (*J. E. D.*).—Withering's "Arrangement of British Plants" contains all you mention, but, of course, does not include exotics. The seventh edition, in four volumes, is the best.

INSECTS (*Rev. G. T.*).—We believe the caterpillars which have gnawed the young Peaches are those of the Moth *Graphiphora festiva*, and that it is an exceptional circumstance for them to attack this fruit, as the Primrose is their ordinary food.—W.

EARLY PEAS.—Messrs. Carter & Co. have written to us as follows:—"Herewith we send you a dish each of Sutton's Ringleader and Carter's First Crop Peas, both sown side by side, and on the same day, early in January last, at our St. Oyth Seed Farm. You will observe that our First Crop Peas are fully matured, and we wish to state that we picked the first gathering on Monday, the 15th inst. We may also remark that it is the opinion of those who have seen them growing side by side at St. Oyth, that Carter's First Crop Peas are longer in the pod than Sutton's Ringleader, and consequently more prolific. You will, to a certain extent, be able to corroborate this by the samples sent, both of which we pledge ourselves to be true samples according to our trial. In conclusion we feel called upon to state, in justice to ourselves, that Carter's First Crop Pea is not two days later than Sutton's Ringleader, as mentioned in your columns, but, on the contrary, rather more forward in podding."

PROPAGATING AZALEA PONTICA (*Cissie*).—The Ghent or hardy Azaleas are most readily propagated by layers, making choice of those shoots that rise from the base of the plant. Autumn is a good time to layer them, making an incision or cut upwards half through the shoot, and fastening the latter with a peg securely an inch or so within the soil. They may also be raised from seed. We do not know that they can be profitably (privately or for sale), propagated from cuttings. We tried some in that way, but were not pleased with the result. Any of our correspondents who have raised them from cuttings will oblige us by their experience.

GRAFTING RHODODENDRONS (*J. W. B.*).—These are grafted like Apples and Pears, and just when the sap rises in the stock. That kind of grafting known as tongue or whip grafting is the best, inserting the graft low, so that it can be covered with soil. The season for grafting is April and May, and if the stock be in advance of the graft all the better. We are not aware that they are ever budded.

PELARGONIUMS (*C. M.*).—The varieties of Pelargoniums are so numerous, and many differ so slightly from others, that we cannot venture to identify the single flowers you enclosed.

ASPHODEL (*J. C. Beale*).—There are so many Asphodels that it is impossible to surmise what those you have purchased from the vagrant French dealers may be; but we regret to add that it is almost a certainty that you have been cheated. We know many instances in which these foreign dealers have hired a shop for a week in a country town, and sold flowers of impossible colours, and trees to y'd' fabulous fruits, to the too credulous.

OPENING AN ICE-HOUSE (*A. K.*).—The time of day for opening an ice-house with the least danger of melting the ice, we should say, is early in the morning; but practically it is of no great consequence if it is not kept long open.

HEDGE-PLANTING NOW BEHIND PALINGS (*A Subscriber*).—Rooted plants of Privet would do if well watered. Slips would do little good, but they might keep alive, and root in the autumn.

**DOUBLE BULBS IN VAN THOL TULIPS** (*A Subscriber, gligo*).—We have little doubt but that the bulbs had been planted too deeply, and too richly treated. The small bulbs growing had better be treated in a reserve-bed for another season. We should not expect many to bloom well.

**BORDER UNDER NORTH WALL** (*B. B.*).—Good-sized Scarlet Geraniums and Calceolarias would do very well in such a border. To have something out of the common way, Cinerarias, and the herbaceous Calceolarias, would bloom well in such a border all the summer, when they would be done flowering in a greenhouse, or in places more exposed to the sun. We once had a splendid show of such on a north border all the summer. All the Heartsease tribe would do well there all the summer, with rich nourishment.

**FIGS** (*C. P.*).—The Figs are not diseased. Our impression is that the plants get dry at one time, and are soaked with water at another, and the Figs with dryish roots have been caught by the sun whilst the fruit was in a damp state, and the scalding has produced a rusty appearance. Probably the fruit that are so affected will not swell. Plenty of air early would prevent it, with judicious watering.

**PEACH LEAVES FALLING** (*F. H. Lavr*).—There is a trace of white red spider on the leaves—that is, spider too young to be red; and the remedy is plenty of the syringe, especially late in the afternoon. The chief cause of the spots on your leaves is the sun shining on them before air has been given freely in your orchard-house, or some spots in your glass. We have a little Cherry tree all spotted the same way, from two rough scars in the glass, which we had putted the year previously. We drew the end of a small paint brush over the blister and scar in the glass, and there has been no more blotching and burning. Some of the cheap glass is well supplied with these little scars and blisters, and each is apt to act as a concentrating burning glass. We think this will prove your chief remedy. A little paint, or glue, or putty rubbed over such places will avert the danger.

**WEEDS IN PAVED YARD—FUMIGATING** (*A Beginner*).—The best thing for destroying grass between stones in a yard is to sow the space over with salt, so as to make all white, and brush it among the stones; but it will not be safe to sow it within 4 feet of any building. No substitute is better than tobacco smoke; there is tobacco water. For a cleanly wash nothing is better or simpler than quassi water. The strength has often been given. Azaleas are easily propagated by cuttings.

**GERANIUMS ILL-MANAGED** (*Ignoramus*).—We are afraid that your cutting down late in autumn, and repotting them in vegetable mould, which you found in the Willow tree, has pretty well done for your plants, and you had better obtain a fresh stock for your windows. If you had merely pruned your Fuchsias a little in autumn, and left them alone in winter, and fresh pots them as soon as fresh growth took place in the spring, all might have been well. The same as to the Geraniums, if you cut down after the beginning of September. To make the most of your proteges now, we would advise shaking the sour Willow soil from them, washing the roots, and then placing them in much smaller pots, in light sandy loam, and shading a little until they are rooting freely. We mean such loam as you could obtain by the side of the road, with a quarter of rough sand with it. You could give richer nutriment afterwards.

**MULCHING CALCEOLARIAS** (*F. T. C.*).—If your Calceolarias are growing freely, and the ground is moist, you may mulch them at once with rotten dung. If they are not large, and the ground is still cool, and not so moist as you wish, you may delay for a fortnight. We would do our own at once if we could command the material. We publish a full index for each volume; therefore the weekly index is only of importance for that week.

**ADELASTER ALBIVENIS LEAVES SPOTTED** (*Bingley*).—There are spots on the leaf as if scale had been resting on it, but none on it now. If so they must be washed off with soap and water, and then well syringed with clean water. There are other marks that denote scalding, and the remedy is to give air early, so as to have the leaves dry before the sun reaches them.

**CROP OF GREENGAGES IN POTS** (*C. P.*).—From two to three dozen of Plums will be sufficient on a tree if you wish them fine, and not to injure the trees for another year.

**BROWN TURKEY FIGS FALLING** (*Idem*).—We are surprised that your Brown Turkey sheds its fruit, whilst the White Marseilles stands so well, as it forces quite as well as the White Marseilles generally. The best of the latter is Rivers's variety, and that does well with or without heat. Are you sure you have the Brown Turkey? With plenty of water, and yet no stagnant water, no Fig stands better than the Brown Turkey. We have seen several fine trees throw their fruit from being too dry when swelling.

**SHELVES IN A HOTHOUSE** (*A Humble and Constant Reader*).—We have no doubt what you propose will answer; but our opinion is that, for a span-roofed house 16 feet wide, the best plan is to have a stand in the middle, and a walk and broad shelf at each side. All the plants could then be easily reached, but that would do away with your one central path. In looking more closely over your letter we are in doubt if your houses are span-roofed; for, as to the second house, you speak of the back wall, and the expediency of having plants against it, and having a pit in the middle. Well, not to interfere with your pit, you could have a narrow border in front of your back wall, if it is a lean-to house, a walk between the border and the front, and in the pit you might shut off some pieces 2½ feet square for creepers for the roof; but if you take our advice you would make the curb of your pit level all round; and in such a house we would not have the shelf more than 2½ feet or 2½ feet above the level of the pathway. This will enable the observer to see all the plants from either pathway. You can fill your pit with plunging material, or you can use rough stones, and then fine gravel, for setting the plants on. As to slate or gravel, or small washed pebbles, both are very good. Slate is very good, with an edging to hold water; and it is also very good covered with clean gravel to let in a little moisture. Your creepers and Vines ought to be 15 inches from the glass. If in the third house, which you mean for an earlyinery, and to force Vines, a pit in front would be more useful than a stage. In the house for bedding plants every place may be supplied with shelves, and then, in the dark months, many things will stand on the floor. In such a house we have frequently something like three tiers of plants; but then they must be managed according to what they want. Of course the plants would do better in three houses, and give less trouble than so much storing and moving; and we would all like to do so if we could; but many are situated as we are—turn out many thousands of plants every year, and by the first week in June it would not be easy for a stranger to say where such myriads of plants came from.

**NAMES OF PLANTS** (*Gensing Lodge*).—1, *Phlebodium aureum*; 2, *Cyrtodium falcatum*; 3, *Asplenium lucidum*. (*J. F., Coventry*)—1, *Asplenium Adiantum-nigrum*; 2, too little developed; 3, *Polypodium Dryopteris*; 4, *Polystichum angulare*. (*M. D.*)—It is *Allium Moly*, Yellow Garlic or Moly. It is quite hardy. (*A. M. H.*)—1, *Peris tremula*; 2, *Polystichum capense*. We cannot undertake to name varieties of the *Pelargonium* from single flowers. (*C. F.*)—*Rhododendron javanicum*; *Erica ventricosa superba*. (*An Old Subscriber*).—*Lonicera hispida*, and the young shoot sent without flower is probably a species of *Spiraea*. (*Leighton*).—*Hedysarum coronarium*. (*T. J.*)—The large-flowered *Myosotis* is *M. alpestris*, and the other is probably a variety of *M. arvensis*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending June 3rd.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

EFFECTS OF COLD SPRING WEATHER—  
BONING FOWLS.

“The wind of late breathed gently forth—  
Now shifted east, and east by north;  
And Destiny, which sometimes wears  
An aspect stern on man's affairs,  
Not altogether smiled on theirs.”

Too true! bitter cold nights—colder mornings! Chickens looking for shelter. Some that had gone well through the tertian snowstorms of the winter months, and in the fine weather of a fortnight ago grew while you looked at them, these have begun to give up. Cold wind, cold rain, and no sun, all within thirty-five days of the longest day, when (the idea is like going into an ice well) the days will be drawing in. We went once with a very close observer to see an

execution. It was at the Old Bailey, and our friend said, “Do not look at the scaffold, it is horrible, but turn your back to it, and watch the women at those windows.” It was the house looking up Giltspur Street. “Which shall we look at,” said we? “The maid servants at the upper window, they are the most unsophisticated and impressionable.” They were cheerful and almost merry till the clock was on the stroke of eight, then they became quiet and their mouths were set. Then they grasped each other (there were four of them), their brows were knitted, and while a visible shudder passed over them, each closed her eyes for an instant. ’Twas but an instant, and we were then borne along by the crowd, which hurries away the moment it is over. The features of the girls told all the history, and just so, we fancy, our man looks out for us in the morning. Our bedroom window looks out on the chickens. We like to see them stretching all over the field, finding food among the dewy grass, chasing unwary flies, taking stock of an adventurous frog, or drawing an incautious worm out of the

earth as tenderly as Old Izaak impaled a frog on his hook. They seldom break the worm, and if they do we don't believe it feels it. It is a rare sign of health when they take to these diversions, and seek all this kind of food, and our man passes along in front whistling merrily. He has a knack of addressing an imaginary person: sometimes he calls him "Jim," sometimes he speaks through the hedge; but it is curious that his conversation is always where we can hear it, and we never hear an answer. In the fine weather we heard, "I say, Jim, they chickens do grow, I never see things do so well in *my* life, and they eats next to nothing, and yet see how they thrive." But for the last ten days he is perpetually in conversation with the poultry Mrs. Harris. He was looking a day or two hard at a hedge within a few yards of our window, and thus he discoursed, "Ah! you may say that, and you ain't the only person as wonders, I wonders myself that I have patience with them. Three hens off yesterday, all clear eggs, not a chicken. Chickens don't grow a bit, and what they eat is marvellous—in fact, I'll tell you what it is, they terrify me." While peering cautiously at him from the chamber window we can tell the quarter of the wind and the condition of the chickens, as well from his countenance as we could tell the progress of the execution from watching the faces of the girls. When we come down we have a repetition of what Master So-and-so or Dame This-and-that said as they were going to work. We are afraid we are like "Old Joe Bagstock," getting sly. We have learned to parry all these attacks by mildly saying, "We have heard you are not so well off as your neighbours." "Then them as says so knows nothing about it. I have ten chickens to their one. Look here, sir, come this way, sir, there's a brood you have not seen, but this weather is very bad." So it is. We have found great benefit from putting camphor in all their water. We have resumed our winter feeding, and although they will pull through if we have no more snow, we fear most of them will show they have had a bad fortnight in their lives.

We had written thus far when we ourselves suffered as much as the chicks. Bad cold, pain at the chest, nasty little cough—camphor for ever! We make a "cigarette camphrée à la Raspail." Take a sound goose quill, cut it off at the feather, stop the end with some paper, break up some camphor in small pieces, fill two-thirds of the quill, and stop up again with paper. If you are plagued with a "nasty little hacketing cough" keep this cigar in your mouth, inhale air only through it, you will find your tiresome symptoms disappear—Raspail loquitur, "*comme par enchantement.*"

It is said that a friend about to visit England, asked Voltaire, "if he had any commissions for that country." "No," said the poor old infidel; "Yet, stay; should your friend see the sun, ask him to present my compliments to him, I was there forty days, and did not see him once." We shut ourselves up according to medical directions, and in twenty-four hours the sun was shining, and people were complaining of the heat. "Jim," shouted our man, "this ere's a morning. *There*, I do think, them chickens is growed since last night. Lor' a' massy, it does one good. How that grass is growed *surely*. If the chickens did not grow as fast they'd be lost in it. Morning, missis, morning, you be right, 'tis a pleasure to see things, they grows while you looks at 'em. Terrible hot yesterday to be sure, but chickens thrives, and it's a pleasure to look after them."

He waits no more for us to come down, we are obliged to seek him. We know him first by his whistle (he is musical). During the bad weather he has a weakness for the "Dead March in Saul." When he arrives at a bad case, or when he is overcome by the appearance of things in general, he lets loose his drums, big and little; cymbals, wind instruments, all go at a crash. The fit lasts a minute or two, he then captiously pushes his hat on one side, and scratches his head. The last operation restores him. The "Maestro" vanishes into thin air, and the poultry man returns. But when the weather is favourable and chickens do well, nothing less cheerful than "Cheer, Boys, Cheer," will answer his turn, and we believe when we are in search of him, he dodges; for the sounds meet us everywhere, but the man seems as though he had found fern seed, or the four-leaved clover.

"What are we to do with those two young cocks, they've growed out of strength and shape, they sits on their knees

all day, and they'll never sit up?" "Kill them, and take them in-doors." "They be skeletons." "Do as you are told."

"Sarah," says cook to the parlour-maid, "I wish you'd tell mistress I wish to speak to her." "Well, cook," says mistress, "what do you want?" "Why, look here, Fred has brought these two things in, he says they're to go into the larder, they shan't go into *mine*. Nasty, long-legged, ill-looking things, I don't believe as master told him." "Well, well, well," says the mistress, "don't make troubles." (We think in these days the mistress has it hot and strong sometimes). "I will see your master and ask him." The "first blow may be half the battle," but some people think much of the last word, and cook said, "She only know'd one thing, she wasn't going to dress such fowls, no, not if she gev warning as she stood there, and she didn't care."

What on earth had Fred said?

Cook may give warning and leave, but master cannot, so he was brought into the kitchen to say what was to be done with these unfortunate fowls. Poor man, he was in great trouble, he is not a bad husband as things go; but it is said, that now-a-days it is easier to get four wives than one cook. He knew not what to do. When you *must* bathe, and don't know the depth of the water, take a header. He did so, "They are for made dishes." "There, cook," said mistress. Indeed, sir," said cook. "Well, mem," said cook, "praps you will say what made dishes you wish." Mistress looked to master, and he said, "Galantines." Cook knew nothing of such outlandish things, but she didn't mind learning, if mistress would teach her. She did so as follows:—Now, cook, take that fowl's neck just below the crop, squeeze the skin between the thumb and finger till it is tight; now draw your sharp knife down the back of the neck. There, it gapes open. Now, cut off the neck, between the shoulders, do not cut through, but withdraw the severed part of the neck 3 inches below the shoulder. Now, cut through everything so as to divide the head and neck from the body. Remove the crop. I think, now, for the first one or two operations, mistress or master must superintend. The head and neck are cut off, the crop is removed. Place the fowl on its *scant* on the table. Take the outer skin and fold it over backwards all round; the prominent objects will then be the merrythought and the two wings. Scrape the merrythought clean and remove it. Then with a sharp knife disarticulate the wings. Let us digress, boning requires a *very* sharp knife, and clumsy tyros mangle themselves in the beginning, but only clumsy fellows. If you keep the edge of the knife against the bone, and that is where it should be there is no danger. Cut through the wing bones; having done so and removed the merrythought, you will again turn all the skin backwards, and then the leg-joints will appear in view on either side. Strip the skin back over them and divide where the drumstick joins the good succulent thigh, you may pass your knife through below the joint and cut upwards. Now, turn over, scrape out the oyster-pieces, and all the meat of the back. Keep the edge of your knife inwards, and all will go smoothly till the drumsticks are in the way, denude them of all flesh, and having done so, strike the bone a sharp blow with the back of your knife just below the knee-joint, it will easily break. Remove all the splinters of bone. You can then take the bone out of the pinion of the wing, and take all the meat that belongs to the carcase or thighs, or any other part. Continue to turn the flesh and skin backwards, and to keep the edge of your knife towards the bone. When nothing remains to cut, you have boned a fowl. Turn the skin back and look at the carcase, you will find that which has seemed almost a miracle, is the common-place feat you have just performed.

If it stopped here, we should argue with cook, there was nothing to brag about. But we bought two sheep's tongues and boiled them, and we chopped up 4 or 5 lbs. of refuse pork, and we carefully saved the gizzards and livers of the fowls, and we looked for all the scraps we could find till we had a basinful. Then we took the carcase of this long lean chicken and subjected it to a Falstaffian process. We once knew of a country performance where the lean apothecary of Romeo was the Falstaff of Henry IV. Pillows and stuffing my merrie masters. When we laid the Cochinchina carcasses guiltless of bones, they did look flat. A flounder was rotund compared with them. "I won't march through

Coventry with them, that's flat!" "Give me the stuffing." Well, we put some chopped pork, till the bottom was square; then we took a whole sheep's or calf's tongue, we cannot say which, and put that in whole, having first removed cartilage and all that was uneatable, and then we topped up (sic in MS.) with all that came to hand, till our Cochon brother's skin was full, and then we tied him up in a cloth and allowed him to "mijoter au coin de feu," for four or five hours or more, and then took him out and put him in a cold larder, and at breakfast time, all said, as they should say, "Success to the Journal," and the children ate till ma would allow no more, and pa said it would be good for a hunting breakfast; and uncle said it was good enough for a bishop at a visitation; and cook said she had learned something; and Fred said he was only joking; and the two last married and lived close to mistress; and cook used to make a galantine whenever it was wanted.

### NORTH HANTS AGRICULTURAL ASSOCIATION POULTRY SHOW.

At the meeting held at Winchester on the 1st inst. the following prizes were awarded:—

**DORKING.**—First, W. R. Peacey, Chilworth, Tetbury. Second, J. K. Fowler, Aylesbury.  
**COCHON.**—First, Miss J. Milward, Bristol. Second, J. K. Fowler, Aylesbury.  
**GAME.**—First, H. Bertram, Newport, Isle of Wight. Second, S. Dupe, Evercreech, Bath.  
**POLAND.**—First, Mrs. Pettatt, Ashe. Second, T. P. Edwards, Lyndhurst.  
**SPANISH.**—First, Rev. J. De L. Simmonds, Chilcomb Rectory, Winchester. Second, J. Jenner, Lewes, Sussex.  
**HAMBURGERS (Silver or Gold-pencilled).**—First, F. Pettis, jun., Newport, Isle of Wight. Second, W. J. Garrett, Bentworth, Hants.  
**HAMBURGERS (Silver or Gold-spangled).**—First, J. Hunter, New Malden. Second, Mrs. Pettatt, Ashe.  
**BRAHMA POOTRA (Light).**—First and Second, J. Pares, Chertsey.  
**BRAHMA POOTRA (Dark).**—First, R. W. Boyle, Dundrum, Dublin. Second, J. K. Fowler, Aylesbury.  
**ANY OTHER VARIETY.**—First, Mrs. Pettatt, Ashe. Second, J. Hinton, Hinton, Bath (Malays).  
**DUCKS.**—First and Second, J. K. Fowler, Aylesbury.  
**GEES.**—Prize, W. J. M. Pocock, Wonston Manor.  
**RABBITS.**—*Longest Ears.*—Prize, E. E. M. Royds, Ashby-de-la-Zouch.  
*Self Colvi.*—Prize, G. Hill, Winchester. *Foreign.*—Prize, Mrs. M. E. Churcher, Stratton. *Variety* (to include all points).—Prize, G. Hill.  
**JUDGE.**—Mr. J. Baily, 113, Mount Street, Grosvenor Square, London.

### POULTRY AND EGG COMPANY.

It is due to Mr. Geyelin for us to state that we have received from him his printed report to the Directors of this Company, and a letter in which he states that the buildings of the Company are erecting next to the Gas-works, Bromley, adjacent to the London, Chatham, and Dover Railway. Mr. Geyelin has also published a pamphlet on the subject.

### DRIVING BEES.

I HIVED a swarm of bees in a straw-hive on the 21st ult., intending to shake them out in the evening into a Woodbury hive. At 3 P.M. they took flight and settled in a hollow pollard elm tree in a neighbouring field. I should be glad to learn how I can drive them up into a straw-hive. I have tried smoking them and rapping the tree; as a last resource, I have sawed off the top of the stump where they are, and stopped up the various avenues at the side, and made a fresh hole through the decayed wood at the top, and propose setting a bottom board over their present egress, and placing the hive on this. Do you advise my opening a side hole, and blowing in to them with a pair of bellows? Any suggestion whereby I can secure the swarm will much oblige.

Should swarms be shaken in at once into a Woodbury hive with bottom board off, or into a straw-hive first and then driven up into a Woodbury?—B. B.

[We should permit the errant swarm to remain in the domicile it has chosen until the autumn, when by laying bare one side of the cavity the comb may be cut out and fitted into a Woodbury frame-hive. Even if you should fail in securing the bees themselves, their loss at that season will be of little importance, as plenty of your neighbour's condemned bees may, doubtless, then be had for the trouble of driving, and the inhabitants of a couple of hives if introduced

into the ready-furnished domicile will more than compensate for their loss.

We prefer hiving a natural swarm into a straw-hive and afterwards transferring it to the frame-hive by knocking out the cluster of bees on a cloth after dusk the same evening, and setting the Woodbury hive over them, supported on a couple of sticks, previously laid on the cloth in order to avoid crushing the bees.]

### OVER-MANIPULATION.

WITH all due deference to "A DEVONSHIRE BEE-KEEPER," I hope he will sympathise with me when I tell him that the whole of the manipulations related by me at page 369, were necessary evils, being over-sanguine in the autumn of 1864, as to being able to bring through a number of weak Ligurian stocks placed by me in a position this spring not unlike that of my Devonshire friend in the spring of 1863. Unquestionably, had I not manipulated, I should not have lost the black hives, but I should have been minus several Ligurian stocks, and should not have been able to have decided that strange bees kill queens of other hives, thus fully illustrating the old saying, "There's ne'er a loss but there's aye some sma' profit."—A LANARKSHIRE BEE-KEEPER.

[I can fully sympathise with my Lanarkshire friend, and if he were in anything like the difficulty in which I found myself during the summer of 1863, do not wonder at his resorting to over-manipulation in the endeavour to extricate himself.—A DEVONSHIRE BEE-KEEPER.]

### DEATH OF A QUEEN—FERTILE WORKERS.

IN your remarks on the letter of "J. M. W.," at page 392, of your Journal, you say that a young queen was reared after the expulsion of the old queen, and that she remained a virgin owing to the non-existence of drones, and so she became a drone-breeder. Now, in this statement you are certainly mistaken, as the queen that was thrown out was the identical old queen that was found on the combs on the 4th of April, as she had the same piece torn out of one of her wings, and corresponded in every other respect to that identical old queen.

We did not, as you say, make any mistake in joining the other stock of bees and fertile queen to the stock that contained fertile workers and drone brood in worker cells, by not first removing the living drone-breeding queen, because there was no living queen in the hive, and so she could not be removed. The combs I carefully looked over twice, and it is rarely necessary for me to do that to find the queen. And the old queen when thrown out had every appearance of having been dead some time, by the mouldiness or fungous appearance when I picked her up, which never was the case with a queen that had not been dead twelve hours. So in both cases you were decidedly mistaken.

I think I may venture to say, that I have joined more stocks of bees in the last twelve months than any person in England, without a single case of quarrelling or loss of bees, and yet I now never use anything but pure sugar and water, and it is perfectly astonishing how successful all these operations turn out, considering these supposed great mistakes. As you say "All's well that ends well."

Now for fertile workers. I was a great unbeliever in their existence, but a case in my note-book seems to prove that they do exist; but I should be glad if some of your correspondents would give us any experience they may have on this interesting subject.—WM. CARE, Clayton Bridge, near Manchester.

[We omit the details copied from your note-book, as they have already been published in another periodical. Similar instances have been before related in our columns, and the one in question amounts to this, that in June, 1864, a young Ligurian queen was missing, notwithstanding which drone eggs were laid in worker cells, and on being afterwards supplied with worker-brood the bees formed seven royal cells which hatched out in due course. The occasional though rare existence of fertile workers was first demonstrated about a hundred years ago, and has since been abundantly confirmed by Huber as well as by more recent observers.

With regard to the incidents related by "J. M. W.," we

are still of opinion that the drone-brood which existed in all stages of development, was due to the presence of a living queen, although the statement as to the diminutive size of the one which was expelled, so far misled us as to make us believe her to be a young princess, instead of which it appears she was really the old original queen with the torn wing. We have, however, now no doubt that she was an exhausted queen incapable of laying any but drone eggs, and that the drone-brood found in the combs was laid by her. Whether living or dead, it is admitted that she was in the hive when the union was effected, and with such strong *prima facie* evidence of her existence before your eyes as the presence of drone brood in all stages, we still consider that a great mistake was made by introducing a second queen without instituting such an examination as would have insured the previous discovery and expulsion of the old one. Unless you possess the gift of clairvoyance and are thereby enabled to watch the proceedings of every other apiarian however distant, we should not be surprised to find you also mistaken in asserting that you have joined more stocks during the last year than any other person.]

### EARTH CLOSETS.

ALLOW me to thank your correspondent "G. S." for the kind and courteous expression of feeling towards myself contained in the Number of your Journal for May 23rd, and at the same time to call his attention to the mistake into which he, in common with Mr. Wilmot, has fallen, of either regarding the form of closet which he has used as the only form, or of supposing the defect in that form of which he speaks as irremediable. The truth is that the larger use of these closets had brought that defect so forcibly before my mind, and at the same time I was led to see so clearly that in order to effect one very great object with myself—namely, that of getting this system introduced into sick rooms and hospitals, there must be something simpler and less expensive contrived, that I once more turned my attention to machinery. The result is a contrivance which is certain in its action, and which almost rivals Mr. Wilmot's scoop in simplicity. I have it in full use in a tolerably large family, and the more carefully I examine it and observe its use the better satisfied I am that the failure of which "G. S." speaks cannot in it occur. I hope Messrs. White & Co. will exhibit some specimens at the coming exhibition at Hereford.—HENRY MOULE, *Fordington Vicarage.*

My attention has been called to a letter in your Journal of the 16th May from the Rev. Henry Moule on the earth-closet system, in which I am alluded to. I should be sorry that either Mr. Moule or any of your readers should suppose that I consider ashes, or rather the small dust obtained by riddling ashes, as a better deodoriser than simple dried earth or clay.

I do not think that anything I have written can bear out this assertion; but, at any rate, my view is this, that, admitting simple dried earth to be the best deodoriser, it is still wisdom to use that sort of dried earth which comes most convenient in any particular situation—for instance, to bring dried earth into a town in the dog-days seems unnecessary, as there is likely to be a sufficient quantity of dust in the streets and houses which must, at any rate, be removed, and the dust obtained by riddling cinders, or the flue-sweepings from adjacent manufactories or foundries, is always available. I believe the more the particular article to be used is dried and pulverised the better, and in this way both dust and closet soil can be made portable and removable without offence. I do not think the earth-closet system could be well carried out in any place where there was not a good system of sewerage, as it is the wet and damp in most places which makes the present water system offensive and unhealthy. I am a great advocate for water as a means of personal cleanliness; but if the same skill and attention which was applied thirty years ago to the water-closet system had been given to the earth-closet system, when cesspools were very rightly abolished, our agriculture and bills of health would have been benefited in an extraordinary degree.

Mr. Moule will be glad to know that his earth system is

extending in many quarters. It has been adopted in Dorchester Castle, which is, I believe, a county gaol, on the recommendation and example of the Derby county gaol. It is also on trial at the Belper union, and I heard the other day of the secretary of a water company who has now established one or two earth closets as an experiment, as he found the water was wasted under the other system. In another quarter it is found convenient to use the refuse sand from an adjacent foundry, as it can be got dry without trouble, and also because it contains charcoal. As a general rule I believe sand is not a very efficient deodoriser, but I find it convenient myself to use it instead of straw for bedding in certain cases; and my gardener, who has an eye to his potted plants, is very glad to use my dried sand, especially when he has converted it into guano by reusing it in the earth closet belonging to his particular department.

Mr. Moule asks, Where will Mr. Wilmot find his coal ashes in India? If he will refer to the tenth page of my pamphlet he will see that I particularly refer to the facilities for obtaining dried earth in that country.

Mr. Moule, by first originating a particular system, and then by his untiring energy in following it up, has made himself a public benefactor; but he must not quarrel with those who, in endeavouring to follow in his steps, may sometimes think they can venture to try and improve on it. Should he at any time visit this part of England he might see his system carried out without the mechanical aid he advocates in a very large manufacturing establishment, both in-doors and out, and in a crowded room. In the Derby county gaol urinals are used with galvanised iron pails beneath, and the contents are poured over the gaol guano store (which is, of course, kept under cover), much to its improvement, and still without causing offence.

The writer who signs himself "UPWARDS AND ONWARDS" rather implies that I must be opposed to the use of sewage as a means of irrigation. On the contrary, I am watching with great interest the trials of its application to land by gravitation, and have just read an interesting pamphlet lately out on the subject, by Mr. Lucius Spooner. I do not pretend to judge of the extensive operations now on trial, but I am of opinion that in railway stations at any rate, and in most public establishments, the dry earth system might be adopted with great advantage, and I do not think the night soil belonging to such places should find admission into the public sewers, but people must be first taught to appreciate the value of what they waste.—E. WILMOT, *Milford, Derby.*

[Here the discussion must cease in our pages.—EDS.]

### OUR LETTER BOX.

**HENS NOT LAYING (W.).**—There is no cause apparent in the account you give that should prevent the fowls from laying. It may be they have laid out for the present. Your twelve Hamburgs did well, when they provided nine eggs per day. The Cochins have, probably, gone off from change of food, soil, &c. They will, doubtless, lay again, but you must not be surprised if they are broody. It is not uncommon in June. The hens are in an inflammatory state. Give them some lettuces to eat and withhold all whole corn. Let them have meal.

**MORTALITY AMONG CHICKENS (G. F. W.).**—Your food is not good enough to rear chickens upon. Give ground oats mixed with milk; boiled egg chopped fine; bread and milk; chopped, boiled, or roasted meat; curd, &c. Add a little good beer to drink, and they will soon do better. They are suffering from poverty. Rice and potatoes are the worst of food for young chickens.

**CHICKENS DYING WHILEST HATCHING (J. P.).**—We believe your chickens die in the shell, because the eggs are kept too dry. It is well and profitable to moisten them for a week before hatching. When the hen is off, dip your hand in water and wring it over the nest, sprinkling the eggs thoroughly. Hens of every breed, when in a state of nature, leave their nest in the morning, and return to it draggled with dew—wet as if they had gone through a river. It is for this reason all their eggs hatch, but if they are kept hot and dry the inner membrane becomes as tough as indian-rubber, and the chickens, unable to get through it, die in the shell.

**MICE IN NESTS (Percy Cross).**—It is very likely some of the eggs were broken and the chickens killed by the hen in attacking the mice. Anything that disturbs the hen when sitting puts the eggs in jeopardy.

**REARING YOUNG SWANS (R. H.).**—When the Swans are first hatched, they should be fed with meal put in water. When they are older, they may feed out of a vessel some inches deep. The bottom should be covered with a soil of grass; on this put some meal, whole corn, and scraps of bread if you have any. They will often feed greedily in this way, when in any other they reject food.

**PIG FOOD (R. A. J.).**—A pig fattens equally well upon corn either ground or crushed. There are machines which grind corn into flour. Your query about stocks is answered last week, in replying to another correspondent.

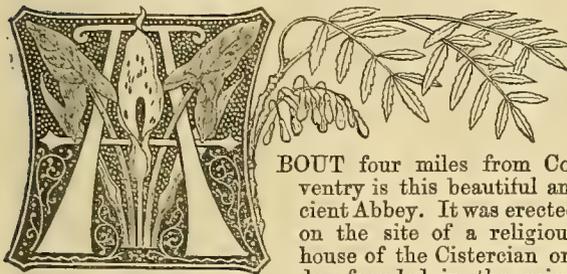

**BEE GLASSES (Whitchurch).**—Look at Messrs. Phillips & Co.'s advertisement. Their warehouse is 180, Bishopsgate Street Without, London. Write to them, and tell them what you need.

WEEKLY CALENDAR.

Day of M'nth	Day of Week.	JUNE 13-19, 1865.	Average Temperature near London.			Rain in last 38 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock after Sun.	Day of Year.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 72.3°, and its night temperature 48.8°. The greatest heat was 93° on the 19th, 1846; and the lowest cold, 30°, on the 15th, 1850. The greatest fall of rain was 0.34 inch.

COMBE ABBEY,  
THE SEAT OF THE EARL OF CRAVEN.

BOUT four miles from Coventry is this beautiful ancient Abbey. It was erected on the site of a religious house of the Cistercian order founded in the reign

of King Stephen, and is said to have been the first settlement of the monks of that order in this country. Of the ancient monastic pile a portion of the cloisters only remains; the greater part of the present building was raised by Lord Harrington. On the west side of the house is a large addition, which, though externally of a heavy appearance, contains some noble apartments. The rest of the edifice is of the Elizabethan style. An historical interest attaches to this building. It was here that the Princess Elizabeth, daughter of James I., the beautiful and unfortunate Queen of Bohemia, passed the early days of her life under the tuition of the accomplished Lord Harrington. From this spot the Guy Fawkes conspirators had formed a scheme to remove her. A party under the pretence of hunting were to assemble near the house, seize the person of the Princess, and by proclaiming her Queen, use her name in stilling and composing the minds of the people. The enterprise was confided to Sir Everard Digby, but the attempt failed, and the Princess escaped to Coventry. The Abbey has altogether that air and those vestiges of old times which must, independent of its connection with the Queen of Bohemia, give it great interest in the eyes of the lovers of old English homes, and of the traces of past generations.

Mr. Bennett, gardener at Brandon Hall, kindly volunteered to accompany me to Combe Abbey. The first impression of the place was very striking. Having walked along what to all appearance was a straight avenue a mile long, we entered the park, Combe Abbey being visible in the distance. The park of 460 acres is well wooded, with several avenues of very old trees diverging from the house. Having passed by the lake (which was being enlarged by Mr. Nesfield), in front of the house, and through the pleasure ground, the first object that attracted attention was a ribbon-border on the south side of the garden wall 233 yards long; it was planted with standard Roses at back, then following in successive rows—Trentham Rose Geranium, Purple King Verbena, Christine Geranium, yellow Calceolaria, blue Lobelia, Cerastium tomentosum, and then a broad verge of grass. On the west side were similar borders, 40 yards long, at each side of the entrance to the kitchen garden,

with a chain of circles planted in the following order:—Christine Geranium, Baron Hugel Geranium, Flower of the Day Geranium, yellow Calceolaria, Tom Thumb Geranium, with Ageratums, white, scarlet, and purple Verbenas, edged with Cerastium, planted in squares around the circles. Each side was planted alike, and a row of noble specimens of Humea elegans filled up the background. This arrangement had a beautiful effect.

The kitchen garden is entered through an ornamental screen composed of varnished oak, and erected in the mediæval style. It is in the form of a parallelogram from east to west, with a walk 12 feet wide running up the centre and terminated by a new and beautiful garden-house, and a cross walk divides it into vegetable quarters. At both sides of the main walk are borders, 8 feet wide, planted ribbon-fashion, with Trentham Rose Geranium at back, then a row of Lord Raglan Verbena, then Flower of the Day Geranium edged with the small-leaved Ivy from the woods. This Ivy is also employed for edging all the walks in the kitchen garden, and very suitable it is for the purpose. In the centre of the cross walk, and parallel with the main walk, is a large circular basin furnished with five jets; the ribbon-borders are carried round the basin and along each side of the cross walk, and are planted similarly to those by the main walk. From this spot a bird's-eye view of the park is obtained through a pair of iron gates on the south side of the garden.

Against the north wall, and facing the south, is a noble range of glass in eight divisions. The two end divisions, or the first and eighth, are each 50 feet by 12, and are planted with Peach and Nectarine trees taken for the most part from the walls in June, 1862; they are fine healthy-looking trees. The second and seventh divisions are succession-houses, each 40 feet by 15, planted with Buckland Sweetwater, Black Hamburg, Golden Hamburg, Pope's Hamburg, Victoria Hamburg, Black Prince, and Sweetwater. The third and sixth divisions are also vineries, each 45 feet by 12, planted with Syrian, Canon Hall, Muscat of Alexandria, Passe Musqué, and Bowood Muscat. The fourth and fifth divisions are late vineries, each 50 feet by 18, containing Champion Hamburg, Victoria Hamburg, Barbarossa, West's St. Peter's, and Lady Downe's. They are all planted inside the houses with arches to allow the roots to pass partly outside. The borders are composed of good maiden loam resting on about 9 inches of rubble. In the middle, and in connection with the range, is a corridor in which are two tanks that hold about four thousand gallons of water each, having a four-inch pipe, flow and return, passing through them; thus affording, when necessary, a constant supply of hot water for the use of the houses.

Midway between the fountain and the east end of the garden was a cross wall, and instead of pulling it down Mr. Miller, the head gardener, very judiciously converted it into two Peach-cases, leaving an opening in the centre 26 feet wide, and carrying the front glass the height of the wall, and covering it with a flat span-roof. The trees are planted in front, and trained along the middle of the

cases on wire trellises 5 or 6 feet high. The back wall is planted with trees also on wire trellises, and by this arrangement the trees are all freely exposed to the light. On entering the garden from the west end next the Abbey, these cases have a very ornamental appearance in front, and at the same time serve as a beautiful screen to the plant-houses at back.

The greenhouse, 75 feet by 18, contained the usual assortment of plants. Amongst them were Geraniums Lord Palmerston and Bendatler, the latter with a large pink truss of well-formed flowers, and *Cassia corymbosa*. The stove and fernery together are 75 feet by 18. The Ferns occupy a length of 35 feet, and stove plants the remainder. Conspicuous among the latter were the *Allamanda Schottii* and *nerifolia*, *Croton variegata*, *Passiflora quadrangularis*, tree Ferns 8 feet high, *Polypodium aureum*, *Pteris argyræa*, and several others in a most luxuriant state, with the *Cissus* discolor gracefully hanging from the roof all over the house. In the Fern compartment is a series of double arches against the back wall for supporting two borders in which Ferns are planted out of their pots. In front of these is a tank of heated water, and a stage over it for setting Ferns on. Behind this are arranged, one on each side, a house 80 feet long by 15 wide, heated by hot-water pipes and a tank, and containing Cucumber plants bearing fine fruit and a succession of young plants, and another of the same dimensions, in which were fine crops of Melons. The sorts were Monarch, Chichester Prize, a large fruit, and Brandon Green-flesh. On the other side, to correspond, are the fruiting and succession Pine-pits.

The improvements in course of being carried out comprise a Rose garden, a Rhododendron or American garden, and a miniature fruit garden, and the soil dug out according to the instructions of Mr. Nesfield, to enlarge the lake, is intended to form a beautiful terrace garden. In the pleasure grounds are some fine old Oaks, Spruce and Scotch Firs, and other forest trees and shrubs. Every tree is in perfect beauty, feathered to the ground, and the outlines of the groups and of the plantations indicate a state of nature, free from the interference of cattle, most favourable to this landscape scene.

It is only three or four years ago that the old and dilapidated garden walls and houses were taken down, and the present new walls and horticultural buildings erected by Mr. Gray, of Danvers Street, Chelsea. The remodelling of the kitchen garden and the many other improvements carried out and in the course of completion, reflect much credit on Mr. Miller. His exhibitions at the Royal Horticultural Gardens attest his practical abilities, and a visit to Combe Abbey will prove that he is the right man in the right place.

While Mr. Miller was engaged with a friend I took a stroll into the young men's apartments, and I was delighted to see the accommodation provided for them. Mr. Miller, to his credit be it said, when erecting the beautiful horticultural buildings and garden-house, did not forget to provide comfortable accommodation for the young men who lodge on the premises. While an individual is surrounded by discomforts, it requires a greater share of fortitude than falls to the lot of many, to resist temptations which offer pleasure as well as comfort. To prove the difficulties and temptations, it is only necessary for the writer to recall to his recollection the many instances when time was misspent and frivolity the disorder of the evening. As the services of young gardeners are required during the evenings, to attend to fires in the forcing department, it is unkind, to say the least of it, to lodge them in sheds too often unfit for human habitations.—WILLIAM FARRE.

## PROPAGATING AND AFTER-MANAGEMENT OF BEDDING AND OTHER PLANTS.

(Continued from page 376.)

THE soil most suitable for propagating nearly all kinds of bedding plants is a mixture of loam, leaf soil, peat, and silver sand in equal proportions. After this has been well incorporated together it should be sifted through a sieve about half an inch wide in the mesh, and a finer sieve should be used for sifting the soil the second time. The small lumps of soil, sand, &c., that will not pass through the riddle this

time should be saved for putting on the top of the drainage to prevent the fine soil from running down amongst it. I have often seen large lumps of fibrous peat, moss, loam, &c., put in on the drainage for this purpose; but this is a very bad plan, and it should be avoided for this reason: after the cuttings are struck it will be found on turning them out of the pots that the roots from many of the plants have grown into a single piece of moss or fibres, and these cannot then be disentangled without injury to the roots of many of the plants. When this happens loss of time in the growth of the young plant is sure to follow; for instead of its starting off into vigorous growth in a day or two after it is potted off, the energy of the plant is necessarily occupied in forming new roots to replace those that have been broken during the process of shaking them out of the cutting-pans. Where, on the contrary, the fine siftings are used on the top of the drainage instead of the fibrous lumps as described above, the cuttings can be easily separated without doing much harm to the roots.

When the soil is properly prepared see that the pots or pans, whichever are to be used for putting the cuttings in, are quite clean, especially inside. If dirty pots or pans are used, when the fresh lot of cuttings are turned out, it will be found that a large portion of their roots has been left sticking to the sides of the pots. In preparing the cutting-pans place about 2 or 3 inches of broken crocks in the bottom, putting in the larger pieces first, and finishing off with small pieces. On this place the siftings from the cutting-soil in sufficient quantity to fill up the small openings between the crocks; then fill the pot full of the prepared soil, and give two or three sharp taps on the potting-bench to shake the soil in evenly. Press the soil moderately firm with the points of the fingers, and give the pot two or three more taps on the bench. The surface of the soil should be about half an inch below the rim of the pan. Next place a quarter of an inch or so of finely sifted sand on the soil, or, if the sand is put lightly on and scraped off level with the top of the pot, the sand should then be pressed down firmly with the bottom of a small flower-pot. This will leave a space of about a quarter of an inch between the rim of the pot and the sand. The small space above the sand is required to hold the water when the pans are watered. If the surface of the sand is level with the rim of the pot, and the cuttings are left long after they are struck, the sand gets baked or cased over, and the water, instead of soaking in to nourish the plants, runs off, leaving them quite dry. A batch of cuttings left in this way soon becomes infested with green fly, and when once this pest takes firm hold the pot of cuttings might as well be thrown to the rubbish-heap.

The sand when used should be in a nice moist state, and should not be watered before the cuttings are put in. I mention this particularly, because I have often seen persons after they have beaten the soil into the cutting-pans with a wooden mallet, toss them into tubs of water two or three times to consolidate the sand. This is one of the worst plans that could be adopted, for it soddens the whole mass of sand and soil, and the consequence is that a large portion of the cuttings damp off or refuse to emit roots. My plan is never to water the cutting-pans until the cuttings are all put in, unless these are very small, when it is necessary to have the surface rather firm. In dibbling in the cuttings be careful to place the base of the cutting on the bottom of the hole made by the dibber, then press the soil firmly around the sides of the cutting. After the pot is filled water with a fine rose, but only in sufficient quantity to consolidate the sand about the cuttings. If the soil is in good order—i. e., neither too wet nor too dry, very little water will be required between the time of putting the cuttings in and potting them off after they are rooted.

In taking the cuttings off great care should be exercised, especially if a large stock of any one kind of plant is wanted in a short space of time, and the stock to work from is very limited. It is not necessary to take the cuttings of *Verbena*, *Lobelia*, *Petunia*, *Calceolarias*, *Fuchsias*, &c., off at a joint. By doing so, two cuttings are sacrificed in the first place, and two-thirds of the number of plants that might have been struck from the same plant. My mode of proceeding is as follows: Let us take, for example, a plant of any of the above-named kinds, such as would be sent out

by a nurseryman—and such, if new, are generally small, having only a single stem. If the plant on its arrival were in good condition and had not travelled far, I should at once place it in a warm and rather shaded part of the stove or forcing-pit. On the second or third day after its arrival I should take the top of it off below the first pair of leaves, and as near the next pair as possible, so as to give as long a stem as possible below the first pair of leaves. The cutting should then be put in the cutting-pot, taking care that the base of the leaf or leafstalk is a little above the surface of the sand. If the cutting is inserted below the leafstalk the two buds at the base of the leaf will be spoilt. In three or four days, if the cutting has been properly treated it will have made roots, and in five or six days another pair of leaves, which may be cut off, the same as described above. By this time the parent plant will have sent up two shoots from the eyes at the base of the leafstalk, where the first cutting was taken off. As soon as the plant has made two pairs of leaves cut out the top pair; the plant will produce for the next crop eight cuttings, and will still go on increasing. Meanwhile the cuttings that have been taken off will be increasing in like proportion, so that in a short time from one plant a large stock may be produced. To illustrate this more fully I may mention a case in point that has occurred this spring. In February I had only two small plants of *Iresine Herbstii* or *Achyranthes Verschaffeltii*; from these two little plants, by working them on the system described above, I have propagated about 1300 plants. This, by-the-by, is likely to prove one of our very best bedding plants. It is far superior to *Amaranthus melancholicus*.—  
J. WILLS.

(To be continued.)

### THE HYDRANGEA.

WHILE the discussion on the character of the soil and situation suitable for the well-being of the *Rhododendron* is going on, I would call attention to another plant not by any means so generally cultivated as it deserves to be, but which at the same time seems to be more affected by certain soils than most other plants, though the causes which produce so changed an appearance are by no means well understood. The plant to which I allude is the *Hydrangea*, which, though quite hardy, is not so extensively planted out as it ought to be. The variable character of its flowers when the plant is grown under certain circumstances has for many years been a sort of horticultural puzzle, which is still far from being satisfactorily solved. Plants with bright pink flowers and those with flowers of a tolerably good blue are not unfrequently met with in positions near each other, and apparently in soils exactly alike, while plants grown in an ordinary manner for the most part have either all pink or all blue flowers, as the circumstances of their abode may determine. Now and then certain modes of treatment, directed by skilful cultivators, present us with plants producing flowers of both colours; but that every attempt to change the colour of *Hydrangeas* is not attended with the desired success is a fact that need hardly be mentioned, and the many failures which have occurred have led to the conclusion that the proper means to accomplish the end in view are not yet sufficiently understood to be depended upon.

Some time ago Mr. Shearer, the very intelligent gardener at Yester, stated his views on this subject in *THE JOURNAL OF HORTICULTURE*, and pointed out that iron rust would not always effect the change in colour so much desired. Mr. Shearer also showed, that experiments had been made which proved that much uncertainty existed whether the means employed were those absolutely effecting the change, or whether such alteration in the colour of the flower was not due to some other cause of which we are still ignorant. Be this as it may, *Hydrangeas* blooming pink and others blooming blue have been known for many years, and it remains yet to be proved whether iron in some form has anything to do with the change or not; but certain it is that the removal of a plant from a soil in which this element is only found in very minute particles to one in which it exists in greater abundance does not for some time produce any change, yet that a change does eventually take place in most cases (not all), is also generally admitted. Now to what cause is this change

due, and why is not the bloom of other plants affected in a like manner? This problem is highly suggestive of study, and offers a fair field for experiment.

In general, *Hydrangeas* growing in a peaty soil flower blue, while those in soil of an opposite character produce pink flowers, but there are exceptions in both cases, and this reminds me of your correspondent, "E. C. E.," at page 303, mentioning how well the *Rhododendron* thrives in some of the dells, as well as elevated positions, in Cornwall and Devon. I believe the same may be stated to be the case in most of the western counties, as far north as Cumberland, and probably still further north; but every hill and eminence is not suited to the *Rhododendron*, nor blue *Hydrangea*, and it is wonderful how the line of demarcation is drawn in some places. Some years ago I happened to be at Mount Edgcombe, near Plymouth, and Mr. Pooley, the then gardener, pointed out the boundary line separating the blue *Hydrangea* from the pink one, which was also the line of demarcation, indicating where the *Rhododendron* ceased to do well. These boundaries, though not so marked as those of land and water, were nevertheless very evident. The most probable theory as to the cause of such variety in the crust of the earth is that at some early convulsion, something was thrown to the top at one place, which differed in its chemical constituents from what was exposed at another, though the two might be adjoining, and that each through the many ages of the world's history has maintained that difference. Though iron in some form may be said to exist to a considerable amount in most of the soils producing the blue *Hydrangea*, and though *Rhododendrons* thrive best in a soil in which this element is also found, yet I am not sure that we have not overlooked some still more active agent as being the cause in both cases. As a proof that iron alone will not always change a pink *Hydrangea* into a blue one, I may mention that large quantities of that metal have been at times added to the soil without the desired effect. Neither has alum dissolved in the water applied to the plants been always attended with success. On the other hand, now and then a plant will produce blue flowers without any apparent cause, so that we are sometimes almost led to the belief that caprice has something to do with the matter. It is almost unnecessary to say that is not the case, but our knowledge of the cause of the change is far from perfect. Time is always required, even when the elements necessary to effect the change are present, and a plant that has been growing under conditions favourable to the production of pink flowers, will not produce blue in the first season that it is removed to a soil where blue flowers are the rule. This slow change is easily accounted for, and need not be commented on, as the *Hydrangea*, like most other deciduous shrubs, sets its bloom-buds in the preceding autumn, and their expansion the following season will be in accordance with the character of the material in which they have been formed, but in course of time, in consequence of the new food, the juices of the plant become changed, and flowers of another character are prepared. This change may possibly not be effected, even in the second year, as I have witnessed, but it is sure to follow.

Notwithstanding the general hardness of the *Hydrangea*, it is not by any means so generally grown as it deserves to be, and in some cases where it has been injudiciously planted out in a damp situation its summer growth is not sufficiently ripened before winter sets in, and there is, consequently, no blossom. A low damp situation is by no means suitable to it: a dry, sunny, and airy one is more in accordance with its wants, and I believe the largest plant I ever saw of it was in a very exposed situation in Northumberland, elevated considerably above the surrounding country, but, at the same time, dry, the subsoil being the loose shatter stone overlying a freestone quarry. This plant flowered pink, as might be expected from such a soil; but if it had been growing in a valley not more than a stone's throw from its position, in all probability it would have produced blue flowers, if indeed it had bloomed at all, as a black peat morass of considerable depth formed the base of this quarry, thus showing how soils of a diametrically opposite character may be found in juxtaposition. I am not aware whether *Hydrangeas* were ever tried on this morass, but I have seen plants growing on a soil partaking largely of ferruginous matter, and the flowers were generally of a very good blue

and last summer a gentleman brought me some blooms of *Hydrangea japonica*, a species certainly inferior to the older one, and this was perhaps a brighter blue than I ever remember with the old one. The plant was growing on a dry sandy soil where the *Rhododendron* and others of its kindred were quite at home.

It is certainly remarkable that few, if any, plants show such a difference in the character of their flowers as the *Hydrangea* does when planted in soils favouring the two extremes. Most plants to which chemical and other substances are sometimes applied exhibit a difference in their general health as well as in their foliage, but the *Hydrangea* possesses as robust health in the one condition as in the other; at the same time we may be right in assuming pink to have been the original colour. Its change to blue seems to be due to some soluble substance contained in the soil and taken up by the plant, and carried through its system into the flower-buds. There may also be some peculiarity in the plant favouring the storing away of such soluble matter as will effect the change. Iron is the only substance that I have experimented with, and then only with varying success, but alum or some other salt may effect a change; still the light thrown on the subject is far from being satisfactory, and discussion may doubtless bring about a better understanding.

I cannot conclude without adverting to a very common disappointment—namely, that this plant will not produce blue flowers when grown in a pot and in peat soil, and water impregnated, perhaps, with chalk or lime is supplied to it from a well. Water of this kind neutralises the effects of the peat, and the flowers are pink instead of blue. I believe many of the so-called failures in obtaining blue flowers arise from this and similar causes. I may also add that such water given to Heaths and kindred plants growing in peat soil is at all times hurtful, as the soil and the water have opposite effects; and in the case of the *Hydrangea* it is useless to expect a good result from a mixture of opposite ingredients, as the chemical properties wanted in a soil must not be neutralised by the water administered to it possessing those of an opposite character, as the object sought after is rather an extreme than a neutral combination. Those, therefore, who expect to have blue flowers on *Hydrangeas* ought to be careful what description of water is supplied to them; and it is not too much to say that this has really more to do with the success of the plants than the soil they are grown in, but to make doubly sure the one as well as the other ought to be duly attended to.—J. ROBSON.

#### EARLY POTATOES.

I HAVE this day, May 20th, had my first "taking up" of young Potatoes. In No. 198 I have given an account of my method of cultivating my first open-air crop, I have followed the same plan this season with this difference—the weather was so inclement all February that I could not get the bed made till the beginning of March, and I did not plant till the 12th. Owing to our peculiarly gratifying unfrosty spring I had but few occasions to throw mats on the hoops—i.e., arches of slight stakes—during the whole month of April, not more, I think, than five or six nights; fortunately I did so on the night of the 30th, and thus saved my flourishing crop from being cut down to the ground.

My bed is 70 feet long and 6 feet wide. I take some credit for a little regularity in planting; for, knowing that we always become anxious to have new Potatoes when May is well advanced, I provided for a little waste in taking them up when only half grown. I therefore planted my rows 10 inches apart, and the sets 9 inches apart in the rows, 8 across, intending to take up every alternate row while quite young, leaving the others to perfect their growth. The plan has answered admirably. We have had, without any twinges of conscience on account of waste, young Potatoes every day since the 20th. I planted only two kinds—the Early Ten-week and the Royal Ashleaf; the former really deserves its name, for exactly ten weeks, less one day, had elapsed from the planting day, March 12th, when they gave from six to seven to each root, were as large as pullet's eggs, and quite delicious. The latter were not quite so large, but then each root gave from twelve to fourteen tubers of excel-

lent flavour. The 60 feet of my bed planted with this sort was, and still is, a most gratifying sight, not a single tuber missed growing, and every bine is of the same regular growth, not a blossom to be seen, and remarkably robust.

To those who like young Potatoes I cannot help giving some small advice. They should be cooked within an hour after being taken up, and if delicacy of flavour is admired this rule should not be departed from till the end of October. The tough, indigestible, young Potatoes sent to the London markets from Cornwall and other distant places are distasteful to those who dig them from their own gardens, and more indigestible than any other vegetable. I look at them when taking my dinner in London in May and June, and avoid them, wishing at the same time that my friends could enjoy the delicate flavour of a freshly-dug young Potato.—FORWARDS.

#### ROYAL HORTICULTURAL SOCIETY.

JUNE 10TH.

ALTHOUGH in many of the classes the competition was very limited, and others were not filled at all, there was a very considerable aggregation of miscellaneous objects, which served with the others to occupy the conservatory and part of the two adjoining arcades. This much of the attendance of exhibitors—that of visitors was likewise not large, and it would appear as if the continuous round of flower shows had begun to tell prejudicially by diminishing their interest.

Among stove and greenhouse plants Mr. Fraser, Lea Bridge Road, exhibited by far the finest plant of *Phænocoma prolifera*, that has been seen of late years, and covered with a profusion of its bright crimson flowers. In the same collection were the showy scarlet *Clerodendron Kampferi*, a very good *Stephanotis*, *Statice imbricata*, a large *Boronia serrulata*, and *Allamanda cathartica*. From Mr. Baxendine came *Hoya bella*, *Rhyncospermum jasminoides*, and a small plant of the beautiful *Clerodendron Thomsonæ* in fine bloom. In collections from Messrs. Lee of Hammer-smith we noticed a large bush of *Erica Cavendishii*, *Ixora coccinea*, fine, a noble example of *Alocasia metallica*, *Rhopala De Jonghi*, *Dicksonia antarctica*, *Imantophyllum miniatum*, in fine bloom, Heaths, Azaleas, and other flowering plants.

Prizes.—For twelve: first, Mr. J. Fraser; second, Messrs. Lee. For six: first, Mr. Kemp, gardener to Earl Percy, Albury Park. For six (Nurserymen): first, Messrs. Lee.

Orchids were likewise not numerous, and several of the prizes were withheld. Among them were *Aërides Lindleyanum*, roseum, and *Larperenta*, some poor examples of *Calanthe veratrifolia*, *Phalsenopsis*, including *Lüddemanniana*, *Vandas*, *Saccolabiums*, a few *Oncidiums*, *Brassia verrucosa*, and *Ladies' Slippers*. *Cattleya Acklandia*, from Messrs. Lee, was very rich in colour.

Prizes—For nine: second, Mr. Robson, gardener to G. Cooper, Esq. For nine (Nurserymen): first, Messrs. Lee; second, Mr. Parker. For six: third, Mr. Robson.

Roses appeared to have suffered somewhat from the sun. Mr. W. Paul, and Mr. Francis, of Hertford, were the only competitors in the Nurserymen's class. The former had a charming plant of *Comtesse de Barbantanne* with about forty of its pale flesh-coloured blooms; *Caroline de Sansal*, beautiful; *Paul Perras*, fine; and *Marquise de Foucault*, pale yellow. The foliage, moreover, had a healthy substantial appearance. From Mr. Francis came *Souvenir d'un Ami* and *Chénédolé*, with large blooms; *Charles Lawson*, *Paul Perras*, *La Reine*, and others in good bloom. Mr. Terry, gardener to W. G. Fuller, Esq., Youngsbury, also exhibited plants in good bloom; and some beautiful Hybrid Perpetuals in nine-inch pots were shown by Messrs. Paul and Son. One of them, *La Brillante*, very dwarf and compact, had no less than a dozen blooms, which did not belie its name, being a very bright carmine. *Madame Charles Wood* and *Olivier Delhomme* were likewise very brilliant. The others were *Anna Alexieff*, with six fine blooms; *Madame Boll*; and *Souvenir de la Reine de l'Angleterre*. A fine collection, upwards of forty in number, was also shown by Messrs. Paul & Son. Of cut blooms, Mr. W. Paul exhibited no less than ten boxes; Messrs. Paul & Son, eight; Messrs. Lee, six; Mr. Clarke, Brixton Hill, the same number; and several came from Mr. Cant, Colchester, Mr. Batley, and

one from Mr. Fountain, gardener to Miss Wood, Hanger Hill. In these stands were beautiful examples of the leading varieties. Among those from Mr. W. Paul were beautiful trusses of Gloire de Dijon and Celine Forestier; whilst Cloth of Gold from Mr. Cant was particularly worthy of remark.

Prizes—For twelve: first, Mr. Francis; second, Mr. W. Paul. For six: first, Mr. Terry. For six in nine-inch pots: first, Messrs. Paul & Son; second, Mr. Francis. For cut blooms (miscellaneous): first, Mr. W. Paul; second, Messrs. Paul & Son; third, Mr. G. Clarke.

In Pelargoniums, again, there was but little competition, and one collection ought never to have been staged, being almost destitute of bloom. Plants in excellent bloom from Mr. Fraser were the only ones shown in the Nurserymen's class. They consisted of Fairest of the Fair, James Lodge, Prince of Prussia, Lord Clyde always very showy, Lillie, Mira, Lightning, Bracelet, Mer Polaire, Leander, Angelina, Douglas, and Lizard. In the Amateurs' class the best exhibition came from Mr. Ward, gardener to F. G. Wilkins, Esq., Leyton, the varieties shown being the same as at the Show on the previous Saturday. In Fancies, Delicatum, Miss in Her Teens, Undine, Cloth of Silver, Roi des Fantaisies, and Hebe, from Mr. Fraser, were very good.

Prizes—For twelve: first, Mr. Fraser. For nine: first, Mr. Ward; third, Mr. Marlow, gardener to J. Wigan, Esq. For six Fancies: first, Mr. Fraser; third, Mr. Marlow.

Of new and rare plants there was a very large assemblage, principally contributed by Mr. Veitch and Mr. Bull, and forming by far the most interesting part of the exhibition. Most of them, however, have been already described in our columns. Mr. Veitch had first-class certificates for a pretty *Pleroma*, *Bertolonia pubescens* and *guttata*, both very pretty; *Maranta Veitchii*, *Goodyera Veitchii*, one of Mr. Dominy's hybrids between *Goodyera discolor* and *Anæctochilus*; *Gymnogramma flexuosa* from Ecuador, with very elegant finely-divided fronds, and of a climbing habit; a Peruvian Begonia, with rich velvety leaves, veined with white; *Philodendron* species with large, deep green, velvety leaves veined with white, *Adiantum colpodes*, *Maranta* species with the foliage spotted black at regular distances from the midrib, a red-veined *Gymnostachyum* and *Anthurium cordifolium*. *Peperomia maculosa* and *Dracæna nigra*, the latter with very dark foliage, were each awarded a second-class certificate, and *Peperomia acuminata* a third. From Mr. Bull came a numerous collection of the *Aucubas* sent home by Dr. Von Siebold differing in the size and marking of the leaves, as well as in the sex of the plant. The green-leaved was also shown in fruit. Many of the varieties were very fine, and to nearly all of them first-class certificates were awarded. As they all rejoice in very long names we shall refer the reader who may be curious about them to pp. 210, 265 of this Journal. Other novelties from Mr. Bull consisted of *Athyrium f. f. Vernoniae*, *Cupania undulata*, *Costus zebrius*, *Pandanus Blancoi*, *Rhodesia* with silvery striped leaves, *Sphærogyne cinnamomea*, *Maranta Van den Heckeii*, *Bertolonia margaritacea*, *Woodsia polystichoides Veitchiana*; the variegated *Podocarpus*, *Privet*, *Sedum*, *Aubrietia*, and *Viburnum*; *Ficus Porteana*, *Peperomia arifolia*, *Calonyction sanguineum*, *Anthurium cordifolium*, and others, for the numerous certificates awarded to which we must refer the reader to the prize list. Messrs. E. G. Henderson had first-class certificates for an Ivy-leaved Pelargonium, called *petatum elegans*, with good trusses of rosy lilac flowers, for *Centaurea ragusina compacta*, for the variegated-leaved *Cheiranthus Marshalli*, and for a *Richardia* with leaves spotted with white. *Hydrangea japonica rosea* with ray flowers white and rose-coloured, had one of the second class. Mr. Thompson, Ipswich, sent *Primula Parryi*, a native of the Rocky Mountains, having pretty rosy purple flowers about an inch across; and *Pentstemon grandiflorus*, also from North America, having lilac flowers much larger than in the better known species. To both of these first-class certificates were awarded; as, also, to Mr. Salter, of Hammersmith, for a variegated *Sedum Telephium*, in which the leaves were yellow edged with green. The variegated *Polygonum filiforme*, also from Mr. Salter, received a second-class certificate. An *Abies* having the character of *A. Douglasii*, was shown by Messrs. Dickson & Turnbull, of Perth; and seedling Pelargoniums by Mr. Fraser.

Other objects consisted of Palms, economic plants,

Petunias, zonate and other Pelargoniums, from Mr. Bull; Pansies from Mr. Hooper, Bath, and Mr. Waymouth; Pæonies from Messrs. Paul & Son; Cacti from Mr. Hurn; Begonias from Mr. Marlow; an interesting collection of variegated plants from Mr. Salter; Dahlias and Roses beautifully executed in rice paper by Mrs. Stoddart; and plant-cases, window-boxes, and ornamental garden pottery from Messrs. Barr & Sugden, and Hooper & Co.

The exhibition of fruit was very limited. Mr. Ruffett, gardener to Lord Palmerston, had a first prize for a noble Providence Pine, and Mr. Standish was second. The best black Grapes were Black Hamburg, large and well coloured, from Mr. Osborne, Finchley; Champion Hamburg, with immense berries, from Mr. M. Henderson, Coleorton Hall, was second; and Mr. Sage, gardener to Earl Brownlow, and Mr. Allen, gardener to E. Hopwood, Esq., Manchester, were third. In White Grapes Mr. Sage was first with very good Muscats, Mr. Horwood second, and Mr. Tansley third, with Canon Hall. Peaches chiefly consisted of Royal George and Violette Hâtive. With the first-named kind Mr. Hill, gardener to R. Hanbury, Esq., Poles, was first; Mr. Allen second; and an extra prize was awarded to Mr. Allen for three dishes of Violette Hâtive. In Nectarines Violette Hâtive, highly coloured, from Mr. Allen, Manchester, was first; and Elruge from Mr. Allen, gardener to J. B. Glegg, Esq., second. Mr. Hill was first in Cherries with an excellent dish of May Duke; Mr. Ruffett second with Belle d'Orleans. In Strawberries Mr. Hill was also first with a good dish of President. J. Wrench, Esq., exhibited Myatt's Pine Apple, a variety supposed to be lost; and Heckfield Seedling, a pale red variety, with the seeds very prominent, came from Mr. Dwerrihouse. The only dish of Figs was one of the Castle Kennedy, of which a representation is given in another page, from Mr. Fowler. Of Melons, the best Green-fleshed were King's, from Mr. Hill, first; and Wills's Green Gem, from Mr. Wills, Oulton Park, second. Scarlet Gem, from the same, and Mr. Gordon, Hampton Wick, was first and second. In miscellaneous fruit Mr. Standish was first with Cherries in pots, loaded with fruit; Mr. Wills second with a fine basket of Black Hamburg Grapes, weighing 21 lbs.; Mr. Horwood third with a basket of Muscats; and an extra prize was given to Mr. M. Henderson for Red Frontignan. Mr. Dwerrihouse exhibited, not for competition, several fruits of Heckfield Hybrid Melon, a green-fleshed sort, of good size and appearance; and Mr. Hill a brace of his Cucumber mentioned at page 378.

#### THE UNITED HORTICULTURAL SOCIETY.

A FLOWER show within a short half mile of the Bank is a novelty indeed; but such an one took place on Tuesday, the 6th inst., in the garden of Finsbury Circus, the first held there, and probably the last for some time, as the Circus is doomed to be invaded by the Metropolitan Railway.

The exhibition was opened in the forenoon by the Lord Mayor and Lady Mayoress, and in the after part of the day there was a good attendance of visitors. The objects exhibited were rather numerous, and comprised some very good specimens of stove and greenhouse plants and Orchids. Along the centre of the principal tent were placed three fine specimens of *Dracæna indivisa*, each about 10 feet high, contributed by Mr. Williams, of Holloway, who also exhibited remarkably fine plants of the Bird's Nest *Neottopteris vulgaris*, *Gleichenia dicarpa*, *Rhyncospermum jasmimoides*, *Statice profusa*, variegated *Yuccas*, *Cordyline indivisa*, *Sphærogyne latifolia*, with large and beautiful leaves, and various other fine-foliaged plants, including two of *Dracæna lineata*, probably the largest in the country. Mr. Williams likewise exhibited a fine plant of *Brassia verrucosa*, *Cypripedium*, *Oncidium*, *Aërides*, and other Orchids, as well as new plants. The latter consisted of *Todea superba*, *Gymnogramma Parsonii*, *Promenæa citrina*, *Peperomia arifolia*, and *Eranthemum sanguinolentum*, having the leaves veined with red.

Orchids were exhibited by Mr. Wilson, gardener to W. Marshall, Esq., Enfield; Mr. Baker, gardener to A. Bassett, Esq.; and Mr. Penny, gardener to H. Gibbs, Esq., Regent's Park; and, intermixed with Ferns and a few small fine-foliaged plants, they occupied a small tent by themselves.

Among them were a good specimen of *Odontoglossum navium*, several good *Aërides* and *Saccolabiums*, *Phalenopsis grandiflora*, in fine bloom, the South American *Cypripedium caudatum*, with three blooms, and several of the tail-less members of the same family, *Cattleyas* and *Lælias*, the new *Phalenopsis Lüddemanniana*, *Trichopilia suavis* in good bloom, &c.

Roses were represented by plants in pots from Messrs. Paul & Son, and cut blooms from the same, Mr. Turner, Slough, A. Smee, Esq., and Mr. Howard, gardener to J. Brand, Esq., Balham.

Of Pelargoniums, both show and Fancy kinds, in excellent bloom, were exhibited by Mr. Fraser, Lea Bridge Road; and from Mr. Turner came a collection of the new kinds sent out by him; one of them, Mary Hoyle, an orange rose with a white eye, and small dark maroon blotch surrounded by orange, was very pretty; John Hoyle, too, is a large and striking flower. Mr. Turner likewise showed *Lilium auratum*, and pot plants of Sir Joseph Paxton Strawberry. There were besides several exhibitions of *Zonale* and variegated *Geraniums*, from Mr. Hally, Blackheath, Mr. Holland, Isleworth, and others.

Of stove and greenhouse plants a good bank was made up by the collections of Messrs. Peed, Rhodes, Baker, Howard, and Wheeler, of Stamford Hill, and Regent's Park. Among them we noticed a plant of the new *Clerodendron Thomsonæ Balfourii* in fine bloom, several fine *Heaths*, good *Azaleas*, *Ixora coccinea*, *Aphelexes*, *Dicksonias* and other Ferns, *Dracenas* and *Marantas*, *Pleroma elegans*, and *Dracophyllum gracile* in good bloom.

Other objects consisted of numerous Pelargoniums, Fuchsias, and Hydrangeas, from Mr. Hayes, Edmonton; Ferns from Mr. Holland; cut blooms of Orchids from Mr. Bullen; *Calceolarias* from Mr. Crute and Mr. Forsyth; Pansies from Mr. Porter; seedling *Geraniums*, a variegated *Achyranthes*, and *Anætochils* from Mr. Aldred; Japanese *Aucubas*, and *Hymenophyllum tunbridgense*, from Mr. Wilson; and plant cases, vases, &c., from Messrs. Barr and Sugden, and Hooper & Co., the latter also showing *Ixias* and *Sparaxis*.

Fruit was represented by sound, well-kept *Dumelow's Seedling*, *Rymer*, and other Apples, and a well-grown Melon from Mr. R. P. Glendinning, of Chiswick. There were also two or three Pines, and some Cherries.

## PROPAGATING FROM BARREN STRAWBERRY PLANTS.

### YOUNG MELONS TURNING YELLOW.

Two years ago I forced some British Queen Strawberries in a vinery, and as several plants were blind, but grew splendidly, I had a clayed bed made for them in my garden, where they have remained till now. Not one flower has ever appeared on them or their runners.

Last year I had a number of runners, layered into sunken flower-pots, in a bed of Keens' Seedling, to form a new plantation elsewhere, expecting, as they formed strong plants before winter, to have a good show of fruit on them this summer. In the old bed were many barren plants, and as my gardener knew nothing of the danger of propagating from such, and as most plants in my young bed show only leaves, I think it probable that he found runners most plentiful about the barren old plants, and that my new bed is consequently to be mostly barren also. He grudges throwing away such very fine strong plants, and thinks they will fruit next year. Do you think he is right or not? I believe they would have all fruited this year had they not been naturally barren.

My Melon plants in tubs, in a piped pit, are as strong and healthy as ever man grew, but I am troubled by the young fruit turning yellow before they even blossom, and falling off. Very few set, though every bloom opening is carefully fertilised. One *Achapesnoiricher* has only one fruit of about 6 inches in diameter, and one of 2 inches; every other has refused to blossom. The plant grows amazingly. A Malvern Hall has plenty of about 3 inches in diameter, but now every female turns yellow before it is the size of a chick pea; and so of other sorts. My tubs stand in cocoa fibre, on four parallel four-inch hot-water pipes. Pray tell me how

to mend matters. Some tubs stand on a stone shelf; all turn yellow in them.—J. MACKENZIE, M.D.

[We do not think your Strawberry plants will ever do any good; they are evidently some worthless sort that has become mixed with your British Queens. The best thing you can do will be to dig them up at once, trench the ground 2 feet 6 inches deep, if your soil is good, and then mark out fresh beds. Put 3 or 4 inches of good manure in the bottom of every trench, and as soon as you can obtain runners from some sort that you are sure is true, plant them on the beds, and if they are kept well watered until they are established in their new quarters they ought to produce a fine crop next year. By putting the manure in the bottom of the trenches the roots are encouraged to go down after it; and afterwards, however dry the season, it will have little or no effect on the plants. These should be well mulched with partially decomposed leaves or manure in the autumn, to protect the hearts of the plants from frost. Your gardener's idea is evidently wrong.]

We think the soil is too rich for the Melons, and that the temperature has not suited them. Subjecting them to a high temperature one day, and to a low one the next, would have just this effect on them; or if they have been allowed to become dry at the roots it would cause them to turn yellow. The atmosphere should be rather dry just at the time they are coming into flower.]

## SIR JOSEPH PAXTON.

WITH deep and sincere regret we have to communicate to our readers the death of this very able and excellent man. We can add little to what we recorded concerning him more than ten years since, for we then commended him, not merely because he was the most successful among the men of genius devoting themselves to the practice of gardening, but because he was the best example we could uphold for imitation to the rising generation of young gardeners. We are often asked by them, "What acquirements should we strive for besides a knowledge of the culture of plants?" and we know of no better reply that we could give than—Attain the same acquirements as those which were possessed by Sir Joseph Paxton. He was a good botanist, a good draftsman, and an excellent engineer, but he had two spirits mighty in promoting progress, presiding over these—the spirit of kindness, and the spirit of perseverance. Every one who associated with him at once felt that genial courtesy and frankness which were to be expected from such an open brow; and the late Duke of Devonshire, who so long aided and benefited by his efforts, may be accepted as the most competent of witnesses to his perseverance, and bore this testimony,—"I never knew Mr. Paxton resolve to undertake what he did not fully accomplish."

Sir Joseph Paxton's entire career sustains that characteristic opinion. He was the son of a small farmer, and born in 1801, at Milton Bryant, near Woburn, in Bedfordshire. We accept this date because it is that which he wrote when engaged at the Chiswick Garden.\*

The brother under whom Sir Joseph received his rudimentary instruction in horticulture, was Mr. John Paxton, successively gardener, we believe, to Sir G. P. Turner and Earl Hardwicke. This gentleman recommended the young gardener to Abel Smith, Esq., and through the latter's influence he was placed in the gardens of the Horticultural Society at Chiswick. Owing to some misunderstanding with some of the authorities of the Horticultural Society, Sir Joseph was about leaving their service and proceeding to America; but whilst this intention was just on the point of being carried out, it is said that he there first obtained the notice of the Society's President, the Duke of Devonshire, whilst holding a glowing cinder for his Grace's cigar. When Mr. Paxton thus attracted the notice of the Duke of Devonshire, he was foreman in the Arboretum department at Chiswick. This was in 1825, and the year following he became the Duke's head gardener and forester at Chatsworth. Here was an arena just suited to his powers, and genius—not only was the space, as he said, "unlimited," but so were

\* He is named in the Report of the Horticultural Society, as one, with many others, who set "an excellent example."—(*Transactions, New Series*, li. 465.)

the funds at his command for its adornment. Writing to Mr. Loudon in 1835, he says:—

“Previously to the commencement of the arboretum, the whole space which it occupies was covered with timber trees: these we have cleared away, so as to suit each genus with light, shelter, or shade, as it might require. The situation, though so much elevated, is yet, by the existing trees, so well sheltered, that, with this aid, our deep trenching, and the supply when necessary, of peat or sandy soil, the plants, in a few years will have made immense progress. There are about 1670 species and varieties already planted; and these will be increased, in a year or two, to about 2000. The whole length of the walk occupied with the arboretum is nearly a mile. The various bends in the walk may be accounted for by the unevenness of the ground, and its steepness in many places. The plants of those orders, the ligneous species of which do not grow large, such as Cruciferae, Cistinea, &c., are planted near to the walk, and occupy both sides of it; and the larger ones, although planted similarly along both sides of the walk, are made to extend beyond the others to a considerable distance from it, as the bare inspection of the plan will show. The whole are planted at such distances from each other as their habits of growth require. Should 2000 more hardy trees and shrubs than can at present be purchased in the nurseries be introduced, there is plenty of space on each side of the walk to plant them. It is rather difficult to say exactly how much ground the plants at present occupy, as we have not measured it; but I think the seventy-five groups cover about forty acres.

“It is a great feature in this business, that the ground, the plants, the formation of the walk, the labour, &c., have not cost His Grace sixpence; the plants having been purchased, the ground prepared, and the trees planted, and all other expenses paid, with the produce of the trees cut down to make room for the walk and the groups. This you should, in some degree, point out to gentlemen who wish to introduce such an important feature as an arboretum in their country seats. At nine places out of ten, throughout the country, an arboretum might be accomplished on this plan; and I scarcely know a country seat where half the trees round the house do not require cutting down.

“In recommending arboretums to those who have got but a limited extent of ground, you should advise them not to plant varieties. We intend doing so, because our space is unlimited: but, if this practice were to become general, the nurserymen would furnish us with catalogues of 20,000 species and varieties, which would put a damp to arboretums at once, from the impossibility both of purchasing the plants, and of finding room for them: and besides, in a few years, the species and varieties would be so confounded, that they would, in many cases, not be distinguishable from each other. I shall keep a young man constantly examining the trees and shrubs in our arboretum, till I have removed everything from it that is not perfectly distinct, and rendered it in every respect as perfect as it can be made.”

The next great works he was employed upon were the Waterworks, the Emperor Fountain of which tosses its waters to the astonishing height of 267 feet. This, and all his subsequent conceptions are among “the most surprising in the world.”

In 1840, he completed the conservatory at Chatsworth, then the largest ever constructed. It required forty miles in length of sash-bars, and to meet this enormous demand he invented a machine for cutting them, which, to use his own words, “performed the labour of twenty men for one year, and consequently saved in money £1200.”

As a literary man he has appeared before the public advantageously, as the Editor of “The Magazine of Botany,” begun in 1833, but now no longer published; as the author, in 1839, of a little volume, “On the Culture of the Dahlia;” as compiler of “Gardening for Cottagers,” and the “Botanical Dictionary,” the first of which was published about the year 1849, and the other about nine years previously.

We have now arrived at the most brilliant period of his life—the construction of the first Crystal Palace. Of its origin in 1850, we must republish the designer’s own account.

“When the six eminent architects and engineers were selected as a committee to choose a design, Mr. Paxton says that he had no intention of offering one, for he took for

granted that something worthy of the occasion and of the nation would be selected by them. When the time approached for the production of plans there was a discussion in the newspapers as to the design best adapted, and he must say that the first sketch he saw in a number of the *Builder*, did not inspire him with any exalted notions, or raise any very splendid expectations of the result. It was not until one morning when he was present with his friend, Mr. Ellis, at an early sitting of the House of Commons, that the idea of sending in a design occurred to him. A conversation took place between them with reference to the construction of the new House of Commons, in the course of which he (Mr. Paxton) observed that he was afraid they would also commit a great blunder in the building for the Industrial Exhibition; adding that he had a notion in his head, and that if he (Mr. Ellis) would accompany him to the Board of Trade, he would ascertain whether it was too late to send in a design. He asked the executive committee whether they were so far committed to the plans as to be precluded from receiving another. The reply was, ‘Certainly not; the specifications will be out in a fortnight, but there is no reason why a clause should not be introduced allowing of the reception of another design.’ He said, ‘Well, if you will introduce such a clause I will go home, and in nine days hence I will bring you my plans all complete.’ No doubt the executive thought him a very conceited fellow, and that what he said was nearer akin to romance than to common sense. Well, this was on Friday, the 11th of June. From London he went to the Menai Straits, to see the third tube of the Britannia Bridge placed, and on his return to Derby he had to attend to some business at the board-room, during which, however, his whole mind was devoted to his project; and whilst the business proceeded he sketched his design on a large piece of blotting-paper. He was sorry he had not the original with him, but the fact was, Mrs. Paxton had taken possession of it, and if they were at all anxious to see it, the only possible way of gratifying their desires was by sending for her to the meeting. Having sketched his design on blotting paper, he sat up all night until he had worked it out to his own satisfaction; and by the aid of his friend, Mr. Barlow, on the 15th, he was enabled to complete the whole of the plans by the Saturday following, on which day he left Rowsley for London. On arriving at the Derby station he met Mr. R. Stephenson, a member of the building committee, who was also on his way to the metropolis. Mr. Stephenson minutely examined the plans, and became thoroughly engrossed with them, until at length he exclaimed that the design was just the thing, and he only wished it had been submitted to the committee in time. Mr. Stephenson, however, laid the plans before the committee, and at first the idea was rather pooh-poohed; but his plans gradually grew in favour, and by publishing the design in the *Illustrated News*, and showing the advantage of such an erection over one composed of fifteen millions of bricks and other materials, which would have to be removed at a great loss, the committee did in the end reject the abortion of a child of their own, and unanimously recommended his bantling.”

We have but little more to add, for having achieved one, the construction of the second Crystal Palace was comparatively easy. He was justly honoured with knighthood in 1851, and the words accompanying the Queen’s smiling greeting in 1854, might have been those used by another monarch to another man of many victories—“If you go on at this rate we shall have to invent marks of distinction for you.”

While the Sydenham Crystal Palace was still in progress the nation had drifted into the Crimean war, and an army was transported to the shores of the Black Sea, but without any of those means of transport and equipment which have been properly called the legs of an army. When the deficiencies of our position were read in the ghastly tales of famine and pestilence that assailed our troops, the fertile genius of Sir Joseph Paxton, was called into play once more. The navvies that were employed in the erection of the Crystal Palace were a band of stout, active, hardy fellows, not devoid of a certain rough discipline, and whose courage had more than once been proved during the erection of the building, by confronting terrors as real as any they were likely to meet with while joining an army in the field. He suggested

*Yours truly  
Joseph Paxton*

to the Government that a body to be called the Army Works Corps should be formed out of these stalwart sons of toil; and the suggestion was at once adopted at the War Office. It is due to them to say that the superior condition of our army at the close of the war was in a great measure due to the assistance rendered by the body raised on the suggestion and from among the labourers employed by Sir Joseph Paxton.

In 1854 a seat for Coventry had become vacant. Sir Joseph was then in the height of his fame, and it was almost a matter of course that a man in his position should enter the House of Commons. He offered himself to the electors on extreme liberal principles, and was elected. He has held the seat undisturbed, but continued ill-health induced him to inform his constituents that at the next election he should not request the renewal of their suffrages.

He remained at his residence of Rockhills, next the Crystal Palace, but though his declining strength had for a long time inspired serious alarm among his friends, latterly it had somewhat improved. On the occasion of the recent flower show he entered the Crystal Palace for the last time, and before the public were admitted endeavoured, as was

his wont, to review the whole display; but he was not able to accomplish a journey round all the stands. During the past week or two his state became gradually more precarious, and at eight o'clock of the morning of the 8th inst., he expired.

Sir Joseph followed the profession of an architect and civil engineer from the time when he constructed the great glass building in Hyde Park; but he did not relinquish his position at Chatsworth. Sir Joseph Paxton was happy in having won the esteem and friendship of many of the greatest and best in the land, who were glad to assemble in a brilliant circle as his guests at Rockhills. But he was happiest in the constant esteem and love, often and truly expressed, of the late Duke of Devonshire. Some time before his own death his patron handed to Sir Joseph Paxton a life policy for £20,000, upon which he charged himself to pay the premiums for Sir Joseph's benefit. This princely gift was the last of many others; but on the accession of the present Duke Sir Joseph had still a firm friend in the Lord of Chatsworth. Sir Joseph was a Fellow of the Horticultural Society, 1826; of the Linnæan, 1833; and in 1844 he was made, by the Emperor of Russia, a Knight of the Order of St. Vladimir.

### CASTLE KENNEDY FIG.

THE Castle Kennedy Fig, of which the annexed figure is a faithful representation, has existed at Castle Kennedy, in Scotland, for upwards of a century, but how it came there, or what was its origin, are matters on which we have no reliable information. It is supposed that at some early period a former proprietor received it from the continent, but whether this was so, or whether it is a chance seedling, is not known, but there can be no doubt that it is quite distinct from any other variety in cultivation in this country. The great distinguishing feature of this Fig in its remarkable earliness. It ripens more than a fortnight before the White Marseilles, which is the only early variety worth cultivating, and as a forcing Fig it also surpasses every other for the rapidity with which it can be brought forward. The fruit from which our present engraving was taken, and which was forwarded to us by Mr. Fowler, the skilful gardener to the Earl of Stair, at Castle Kennedy, was taken from a tree which was begun to be forced on the 20th of February last, and the fruit was ready for use in May.

The fruit is of the largest size, turbinate or somewhat obovate. The skin is of a pale dingy brown on the half nearest the eye, and of a greenish yellow on the half towards the stalk, and the brown part is mottled with ashy grey specks. The flesh when fully ripe is of a dull opaline colour with the slightest tinge of red towards the eye, very melting, and of good flavour. Mr. Fowler says:—

"The Castle Kennedy Fig, when grown alongside the White Marseilles, planted out and treated in every respect in the same manner, is about a fortnight earlier than the latter, fully three weeks earlier than the Brown Turkey, and more than a month earlier than the Brunswick.

"The importance of this will be apparent to those interested in the cultivation of Figs, not only for early forcing, but also for out-door cultivation, as it may be expected to ripen in cold and unfavourable localities where Figs have not heretofore been grown. In our wet and cloudy climate (Wigtonshire), it has ripened out of doors on a

standard, and always ripens on a wall having a south-east aspect, early in August.

"When within a few days of being ripe, a clear honey-looking substance, of exquisite flavour, commences to drop from the eye of each fruit. When quite ripe this substance becomes somewhat viscid, hanging like an elongated dew-drop, from half an inch to three-quarters in length, clear as crystal, giving a very remarkable appearance to the fruit.

"At page 428 of THE JOURNAL OF HORTICULTURE, Dr. Hogg, in addressing the Scientific Meeting of the Royal Horticultural Society, held on the 30th ult., in speaking of the Castle Kennedy Fig, says:—'The fruit, as would be seen, was very fine, and, instead of requiring four months to ripen when forced, it would do so in two, which was a very great recommendation.' Owing to my cramp writing, or some other cause, an error has arisen which I am anxious to have rectified—it should read *three months* instead of 'two months.'

"The fruit of the Castle Kennedy Fig which was before the meeting was com-

menced to be forced on the 20th February. The first ripe Fig was gathered on the 27th April; the first dish on the 23rd May: thus proving that when forced early it can be ripened in about three months. The Figs here are planted out in a border in the inside of the house, and all treated in every respect in the same manner."

Taking it altogether—its size, earliness, and fine hand-

some appearance—this is one of our most valuable acquisitions to pomology.

### DRABA AIZOIDES.

To cottage gardens we are indebted for the preservation of some of our best and rarest plants. A wild flower which has long been in cultivation, one of those choice gems which the Messrs. Backhouse so well know how to use, has flowered splendidly during the spring months. *Draba aizoides* (Yellow Alpine Whitlow Grass), is a most interesting alpine, and one which will well repay a little extra care in its cultivation. It is a plant well adapted for growing on rockwork, and like many of its class its beauty cannot be shown in a small detached piece; to be admired it must be grown in a tuft of some considerable size. Thus grown the beauties of its bright yellow corymbose flowers are rarely overlooked. As it flowers very early in spring it is more to be esteemed, and the flowering season continues several weeks. Besides growing it in rockwork, this interesting plant ought to be grown among the frame alpinists. Then if any losses happen from severe weather, these may be replaced by pot plants.—RUSTIC ROBIN.

## REPORT ON THE BEDDING PELARGONIUMS GROWN AT CHISWICK, 1864.

By THOMAS MOORE, F.L.S., SECRETARY TO THE FLORAL COMMITTEE.

(Continued from page 416.)

### SERIES II.—ZONATE VARIETIES.

#### 2. FLOWERS CERISE, ROSY SCARLET, OR ROSE.

*Alice* (E. G. Henderson & Son).—Vigorous spreading habit; dark-zoned leaves; flowers cerise scarlet.

*Apollo* (Hally).—Vigorous habit; leaves zonate; flowers cerise. Of no use.

*Aspasin*\*\* (Bull).—Moderately vigorous habit; dark-zoned leaves; deep rosy scarlet flowers. The marks indicate its value as a pot plant.

*Beauty*\*\* (Williams).—Vigorous spreading habit; leaves with a broad dull zone; flowers large, rosy scarlet, of good form, and in fine trusses.

*Bonnie Dundee*\*\* (Bull).—Moderately vigorous and compact habit; leaves with a dark well-defined zone; flowers of good form, in compact trusses, of a cerise colour. It is a very pretty free-blooming pot plant, fully deserving on this account an equal number of marks with those given for its bedding qualities.

*Bridesmaid* (E. G. Henderson & Son).—Moderately vigorous; dark-zoned leaves; flowers cerise, with paler edges.

*Caroline* (Bull).—Moderately vigorous; leaves with a broad dark zone; flowers rosy scarlet, in large trusses.

*Cecilia*\*\* (Bull).—Moderately vigorous habit; dark-zoned leaves; rosy scarlet flowers. Inferior to *Roi d'Italie*; but a free showy variety as a pot plant, for which it was approved.

*Cedo Nulli* (Williams).—Dwarf vigorous habit; leaves with broad zone; flowers bright rosy cerise.

*Celina* (Bull).—Vigorous spreading habit; leaves marked with a dull zone; flowers rosy scarlet.

*Chancellor* (Bull).—Moderately vigorous; leaves with a dark zone; flowers salmon rose.

*Cherry* (Hally).—Moderately vigorous compact habit; leaves darkly zoned; flowers cerise scarlet.

*Comte de Clavier* (Van Houtte).—Moderately vigorous; leaves marked with an indistinct zone; flowers cerise. It was poor under glass.

*Comte de Morny*\*\* (Low, Scott).—Moderately vigorous habit; leaves with a broad, dull, vandyked zone; flowers cerise, of fine shape. A very handsome variety for pot culture under glass.

*Conqueror of Europe* (Williams).—Vigorous spreading habit; leaves with broad, dull, vandyked zone; flowers large, of good form, cerise, in fine trusses, but wanting in distinctness.

*Countess* (Bull).—Moderately vigorous; leaves dark zoned; flowers bright rosy scarlet.

*Culford Rose* (E. G. Henderson & Son).—Moderately vigorous; leaves marked with a distinct dark zone; flowers cerise.

*Effective*\*\* (Bull).—Moderately vigorous; leaves with a broad, dull, darkish zone; flowers of good form, cerise scarlet, free and showy. The marks indicate its value as a pot plant.

*Effe* (Bull).—Moderately vigorous; leaves with an indistinct zone; flowers in small trusses, but free, rosy scarlet. As a pot plant it has no particular merit.

*François Chardine*\*\* (Low & Co., Fraser).—Vigorous habit; leaves marked with a dark vandyked zone; flowers cerise scarlet, finely shaped, and in bold trusses. A very fine pot plant.

*General Early* (Wills).—Moderately vigorous; leaves dark zoned; flowers rosy scarlet.

*Giralda*\*\* (Low & Co.).—Moderately vigorous habit; leaves with a broad dull-coloured zone; flowers large, of fine shape, deep cerise.

*Hector*\*\*\* (Bull).—Moderately vigorous habit; leaves marked with a dark well-defined zone; flowers of good shape, in compact trusses, and of a bright cerise. It resembles *Bonnie Dundee*, but is decidedly better. It proved equally good as a pot plant.

*Herald of Spring*\*\*\* (Turner).—Vigorous habit; leaves with a broad, dark, vandyked zone; flowers of fine form, large, in compact trusses, cerise scarlet. A fine variety, larger and paler than *François Chardine*.

*King Arthur* (Wills).—Moderately vigorous; leaves with indistinct zone; flowers cerise.

*Lord of the Isles*\*\*\* (Williams).—Moderately vigorous habit; leaves with a broad dull zone; flowers rosy scarlet.

*Louisa* (Bull).—Vigorous habit; dark zoned leaves; light rosy scarlet flowers.

*Marie Henri* (Van Houtte).—Vigorous spreading habit; leaves marked with a broad dark zone; flowers deep cerise.

*Minimum Nosegay* (Turner).—Dwarf habit; leaves marked with an indistinct green zone; flowers loose, in small trusses, light magenta colour.

*Monsieur Martin*\*\*\* (Rollisson, Fraser).—Moderately vigorous habit; leaves with dark vandyked zone; flowers cerise scarlet, of fine form, in bold trusses. A very fine sort for pot culture.

*Mrs. Turner* (Wills).—Moderately vigorous; leaves with dark broad zone; flowers cerise.

*Nora*\*\*\* (Bull).—Of fine and rather vigorous habit; leaves with a broad dull zone; flowers large and of good form, rosy scarlet, in compact trusses. A fine variety out of doors, and of nearly equal merit under glass.

*Paquitta* (Salter).—Tall vigorous habit; leaves with a dull vandyked zone; flowers cerise.

*Paul Labbé*\*\* (Fraser).—Moderately vigorous; leaves with dull broad zone; flowers large and finely formed, of a salmon rose. A very fine pot plant.

*Pink Pearl*\*\* (E. G. Henderson & Son).—Dwarf spreading habit; leaves rather small, dull green, with a narrow zone; flowers very abundant, of a light magenta rose. Although the flowers were loose in form, they were abundant enough to be very effective.

*President Reveil* (Van Houtte).—Moderately vigorous; leaves marked with a broad zone; flowers cerise, of good form.

*Prince Christian* (Salter).—Moderately vigorous habit; leaves marked with a broadish dull zone; flowers freely produced, of good shape, cerise.

*Princess of Wales* (E. G. Henderson & Son).—Vigorous habit; leaves marked with a dull zone; flowers small, cerise-coloured.

*Provost* (Bull).—Vigorous habit; leaves with a broad dull zone; flowers rosy scarlet, of good form. Tolerably effective as a pot plant.

*Ragalis* (Bull).—Vigorous habit; leaves with an indistinct zone; flowers large, well formed, rosy scarlet, in compact trusses freely produced.

*Roi d'Italie*\*\*\* (Low & Co.).—Dwarf and vigorous habit; leaves marked with a bold dark zone; flowers freely produced, large, of excellent form, salmon or cerise scarlet. A very fine variety for all purposes.

*Rubens Improved* (Carter & Co.).—Dwarfish habit; leaves faintly green zoned; flowers deep cerise scarlet.

*Rubens Improved* (Wills).—Moderately vigorous; leaves with a dark centre or zone; flowers rosy scarlet.

*Empire*\*\*\* (Bull).—Vigorous spreading habit; leaves

with an indistinct and unequal zone; flowers of fine shape, large, in bold trusses, rosy scarlet. A beautiful pot plant.

*Unit* (Bull).—Tall and vigorous habit; leaves marked with a narrow vandyked zone; flowers cerise. Too thin as a pot plant.—(Proceedings of the Royal Horticultural Society.)

(To be continued.)

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

If former directions have been carried out, this department will now present many agreeable features. Continual hoeing, forking, and surface-stirring, together with a splendid season, have told well upon the crops, which are abundant and vigorous. All these operations must be diligently persevered in, for the advantages derived therefrom are manifold, weeds are extirpated, slugs disturbed and destroyed, moisture retained at the time when it is most needed, and the healthy action of the roots kept up. Trenching vacant ground to be prosecuted where required, and if manure is wanted on ground to be planted, it is best to lay it on the top after trenching, and then fork it in. Let all green refuse be removed from every part, and either dug in or taken to the char-heap. *Cauliflowers*, the plants that are now forming their heads to be watered and mulched with short litter; this will cause them to come close and compact. *Celery*, continue to plant successional crops in trenches; take up the plants with as much earth about the roots as possible, and by no means shorten any of their leaves. Immediately after planting give them a good soaking of water. The earliest crops to have the earth loosened about their roots, as the frequent waterings it requires hardens the surface, and prevents it receiving the benefit it should from future waterings. *Cucumbers*, to produce fine fruit the linings of the frames should still be kept up, they should also be covered with mats at night, as it is sometimes cold. After the plants have been bearing for some time, and the shoots become a little irregular, cut them back, give them a good watering, and add 2 or 3 inches of fresh soil. After this keep the plants nearly without air for a few days, shading them when the sun is very powerful, sprinkle the plants with tepid water early every fine afternoon. With this treatment they will make fresh shoots, and will be found as productive as before. *Endive*, make a sowing for the main autumn crop. Plant out a few of the early sowing. Keep them watered till they get root-hold. *Herbs*, some of them will shortly be fit for drying. The best time for doing so is just as they are coming into bloom. *Lettuce*, keep a quantity tied up for blanching. Make another sowing in drills where they are to remain. *Mushrooms*, there is much greater difficulty in producing them at this season than at any other, unless in a house constructed for the purpose. It is necessary to keep the temperature of the house down to 60°, to do this water should be frequently poured down, so as to produce cold by evaporation. *Potatoes*, earth-up the main crops immediately after rain. Keep the ground between the rows loose. *Spinach*, sow a few rows for succession; if the weather continue dry water the drills before sowing, and again after covering them. Whenever it is necessary to water do it copiously, as a slight sprinkling is worse than useless.

### FRUIT GARDEN.

If dry weather continue we would recommend that due attention be given to fruit trees in the above respect, for as caterpillars and other insects are unusually prevalent an extra exhaustion will be the consequence. To those who are particularly anxious about the future success of their favourite fruits, or who have been planting new kinds, we would say, Make strenuous efforts during the present period to extirpate insects, and to assist weakly trees. No mode of planting, winter pruning, or system of training will be of any avail, unless the vegetation of the summer growth is attended to in due time.

### FLOWER GARDEN.

During the continuance of the present dry weather frequent waterings must be given, not only to the recently planted trees and shrubs, but likewise to the bedding plants, annuals, &c. In watering, it will be better to give the soil a good soaking twice or thrice a-week in preference to a

mere sprinkling of the surface daily; mulching where practicable should be adopted, as well as damping the foliage of newly-planted things every evening. Peg down those plants required to cover the ground as they advance. Carnations, Picotees, and herbaceous plants, with the taller-growing bedding plants, to be staked and tied up to prevent injury from high winds. Remove dead and dying leaves from Roses, and give the autumn-flowering varieties plenty of manure water, in order to keep them in vigorous health and secure plenty of wood for blooming in autumn. Divide *Polyanthuses*; always choose for them a cool and shady situation, sheltered as much as possible from north and easterly winds. Mulch Dahlias with rotten dung, and give plenty of water in dry weather. Propagate Pansies by the side shoots. Mark seedlings worthy of being saved, and pull up the others. When showery weather occurs let the Box-edgings be clipped. London Pride, Thrift, Daisies, &c., used for edging should each year, or once in two years, be taken up, divided, and replanted when blooming is over.

### GREENHOUSE AND CONSERVATORY.

Specimen and choice plants nearly done blooming to have the faded blossoms picked off and be well washed with the syringe; to be then placed in a cool shady situation to recover themselves before potting, which should on no account take place until a fresh growth has commenced. Shading will now be necessary for all descriptions of plant-houses, unless the roofs are covered with creepers. Air should be admitted largely, allowing more or less at night, according to the description of plants grown, and the paths, floors, &c., kept damp by throwing water repeatedly over them, to preserve humidity in the atmosphere of the houses, and owing to the extreme dryness of the external air it is rather difficult to do so. Encourage the growth of Azaleas and Camellias by keeping them comparatively close, with shade during sunshine, and supplying moisture liberally with the syringe.

### STOVE.

Achimenes, Gesneras, Gloxinias, &c., as they begin to show for bloom, should be removed to more airy quarters, keeping them, however, partially shaded for a time, and afterwards they may be exposed to a larger share of light. Achimenes to be carefully attended to with water while growing. We must here repeat the advice so frequently given, to keep up by all appliances a sufficient amount of atmospheric moisture, increasing at all times with the increase of heat and light, and accompanied by a quiet motion of the atmosphere. Syringe freely twice or thrice a-day, and give morning air liberally.

### PITS AND FRAMES.

Hardwooded plants in these structures will now enjoy a more moderate temperature than they possibly could obtain in houses, especially in pits turned to the north, which will prove a good place for some of the tribes in very hot weather. Let regular waterings be applied. The bottom heat should be kept up where cuttings and young seedling plants are propagated, and they should be shaded and duly supplied with moisture.—W. KEANE.

## DOINGS OF THE LAST WEEK.

In case we forget to mention it in these rambling notes, we would wish again prominently to direct attention to the in-policy of planting or sowing on stiffish ground when it is at all wet after rain. From having a lot of other matters to attend to we have not got so far on with bedding-out as we would wish in this fine weather; but as the plants are growing nicely in their earth-pits, a few days will make but little difference. Being anxious to get on, however, after the last rains we planted out some four or half a dozen of beds when the surface was not so hazely dry as we would have liked it. Every time we pass them we wish we had left them alone. The surface seems so bound, and sodden, and hard baked that the soil will take much loosening with fork and hoe before it arrives at a nicely pulverised, healthy, sweet condition, whilst the slightest touch of the hoe in the other beds leaves the surface in a nice mellow state—in the best position in fact, as the soil is now warm enough for keeping heat out and moisture in.

Having had many a wet jacket from planting in a day of

pouring rain, we believe we were the first to draw attention to the impolicy of doing so, and especially on stiffish soil, and now some of our labourers, who see some gardening notes in their weekly newspaper, told us that the beds might as well have been left alone, and they were quite right. Such growing intelligence shows the importance of practising what we teach. All teaching is but of little use if not followed up by practical example, and hence it is that many a man and woman in humble station do more good by the example of their lives than many who have great talents, but who, if they were honest, would be forced to say, "Do not as I do, but do as I tell you." Again: several correspondents have kindly told us that after running down the use of the rake, and especially in flower-beds, we actually recommend the back stroke of the rake for effecting neatness (last line, first col., page 435). The seeming anomaly will be at once explained if the word "rake" is changed into "hoe." The mistake is entirely owing to rapid writing.

In answer to another inquiry, we may as well state here that the best-sized *Dutch hoe for flower-beds* is a neat light one 3 inches wide. With such a tool it is astonishing the space a quick lad will go over, and when extreme neatness is an object as well as loosening the surface, the back stroke and a side stroke along the outsides if next grass will leave all as neat as need be.

**Stones.**—If there are stones or pebbles on the surface larger than may be desirable, the quickest way to get rid of them is to pick them by hand in a basket or small barrow, and then they come in for filling ruts in roads, &c. We have no desire, however, to make the surface so very fine-dressed that will soon be covered with plants. We consider that many fields are much injured by inordinate stone picking. A few stones added would often be more beneficial.

**Heap Making.**—This leads us once more to note the importance of never using two strokes when one will do; in other words, to avoid doing and doing again, where one doing will suffice. On this very often depends whether a place shall be kept well or indifferently with a certain number of hands. In nothing is this seen more than in the question of heap-making. Unless in peculiar circumstances no heaps should be made in gardens, and of nothing in general are workmen more fond until they find it will not do. For instance, there goes a man to clear off a piece of spent vegetables, which it is not deemed advisable to dig in, up they come, and then are laid down in heaps as carefully as if for bean or wheat sheaves; and when that is nicely done a barrow must be brought, and there is the great pleasure of lifting the heaps again into the barrow. Last year we came across a fine example of stone heaps on a long flower-border, rather rough with stones, and the proprietor being a thorough advocate of dressiness in grounds, as well as in his own worthy person, the stones had been thrown into little heaps at the side, and then they had to be lifted a second time to get them into a barrow to take them to their destination. A keen amateur, fond to enthusiasm of his charming grass plot, told us lately, that he managed very well with his 14-inch machine, which gave him a nice appetite for his lunch or dinner, but then the taking off the heaps of grass cut with the machine thoroughly bored him. It was worse than all the machining, which he liked very well. He had seen others tumbling out the contents of the grass-box on the lawn, and he thought he must do the same. Placing a barrow in a suitable position saved all the trouble of taking up and cleaning the bottoms of heaps. Just so with clipping the grass edgings to gravel walks. How often do we see a tall, sprightly fellow, "with measured step and slow," draw the broom along these clippings, collecting them into little heaps at no great distance apart, and then another man follows with broom, barrow, and shovel, to collect all these heaps and make the bottom of each all right. A man and boy finishing as they go, would do the work in a fourth of the time, and with more comfort and satisfaction. We have seen brooms used to collect tiny heaps of leaves, &c., on lawns, to be afterwards collected in basket or barrow, if not previously scattered by the wind, though a gardener's apron would have held twenty or thirty of them, and saved all further trouble. In our young days we used to wrap the apron round us, as something of which to be proud. It was considered anything but a badge of inferiority, or to be ashamed of. Are young gardeners now so much gentlemen, as to

despise what their fathers venerated? The more frequent use of the apron would not only expedite much of their work, but preserve their clothes into the bargain. An old comrade of ours invariably in thinning Vine laterals, or thinning Grapes, let all go to the floor to testify that work had been done, careless of the plants below that might be thus inconvenienced or injured. We might have imitated him in the peculiar gusto with which he thus made appearance of work, if, on company being expected, we had not had to work hard all dinner time, go without dinner in fact, to clear off the rubbish we had wantonly made. An apron and a light basket or sieve suspended, would have enabled us to have left work at any moment, and without leaving a vestige of rubbish of any kind behind us. In these days, when few gardeners can get through the work to be done, this little matter of heap-making may be deemed of sufficient importance to arrest a little attention. For the value of the habits it would foster, we would be glad to see the old blue apron more esteemed and used. There might not then be so many heaps of decayed flowers and leaves thrown on the pathways and floors of houses, to the annoyance of every one except the operator, who may, like our friend, be determined to let people see he has been doing something, though this determination may greatly add to his labour.

#### KITCHEN GARDEN.

Much the same as last week. Sowed the last crop of Marrow Peas, such as *Ne Plus Ultra*, and the sweet little prolific *Pea Harrison's Perfection*, and a few of *Dickson's Favourite*. The last and early kinds will be our last main sowing some ten days hence. Sowed also our last Broad Beans, also more French Beans, Turnips, Radishes, Lettuces, &c. Cleared off a piece of run Lettuces, &c. It is yet early enough to have many run Lettuces, but here it may be as well to state that in some matters we have not been able to act up to the advice we give to others. First as respects these Lettuces—they have been very fine and early, and it would have been better had they been used up by those who liked them, instead of being allowed to bolt; but a stress of work elsewhere caused us to neglect them, and for want of water, or shade, or taking them up into a shady place, they have bolted, and are of no use to any one, unless a hungry pig should choose to munch them. Fortunately there are plenty of successions. Planting-out is very well, but frequent thin sowing is the best mode for having plenty of crisp Lettuces, and a north border is the best place during the hot summer months.

**Peas.**—Then as to sowing Peas for late crops, the ground should be deep-stirred, and well enriched, and the Peas sown in a kind of shallow trench, so that manure-waterings may be given if the autumn should be very dry. The deep stirrings and the rich dressings are the great safeguards against the autumn droughts, and also against deluging rains if they come, and pretty well keep all sorts of mildew at a distance. We managed all but the dressing, and even for Celery we must wait until we can empty a hotted. How tantalising it often is to read, "Use plenty of manure for this and that," and you cannot lay your hand on a barrowload. We scarcely know as yet the amount of produce that may be obtained from ground from close and continuous cropping, and without ever allowing the ground to become worn-out, sour, or effete; but the secrets of the wonderful produce, and yet keeping the ground fresh, are abundance of manure, deep stirring, and ever and anon adding to the staple, by first loosening, and by degrees adding a little of the subsoil, whatever be its character. Such means, and a due rotation of cropping, and the addition of lime, or some calcareous matter, if the soil is naturally deficient in these materials, will keep up the fertility of a soil, and prevent its ever wearing out. On some old kitchen gardens lime acts as wonderfully as it often does on bog land, and from similar causes. Even chalk will often do wonders on heavy clayey loams, and advantage should be taken of it wherever chalk underlies the clay or the loam; and again, Peas that are to be staked should have that work done before the tops are sufficiently heavy to have been swayed by the wind, as they never take to the stakes so kindly afterwards. Some of ours, from stress of other matters, have been let alone too long, but if done before wind comes they will not suffer. We will just glance at two common errors in pea-staking. The first is, that most operators thrust the sticks down too

near the Peas, at the risk of injuring some of the best roots. The stakes should be fully 1 foot or more from the row, so as to give room for sun and air to enter freely. And again, most persons place the stakes so as to incline inwards to each other, and even to cross each other at the top, so that when finished the staked row would look like a steep span-roofed house. This plan has neatness rather than utility to recommend it. The higher part of the Peas will pass through and receive but little support from the stakes. The better plan is to place the stakes upright, or rather with their points bent outwards, so as to form a wide-mouthed funnel for the Peas to ramble in. As generally done, the stakes, when finished, have the appearance of a sharp-pointed sugarloaf. We would advocate the same appearance, but with the wide part uppermost.

FRUIT GARDEN.

Much the same as last week, nipping and thinning shoots, thinning fruit, gathering green Gooseberries for jam, though for ourselves if we use any, we are old-fashioned enough to prefer the ripe fruit; exposed Peaches ripening to the sun and air; kept the vinery drier where the fruit is ripening, and as soon as possible will clear out all plants, so that there shall be less moisture in the atmosphere. Removed from the same house many laterals, but not too many, to let more direct light into the house. Have taken but few away yet from the later house, as in moderation they increase root-action. No syringing has been given since the Vines broke, and in one large house no syringing was given at all. Sprinkling a little water on the paths and borders seems to give all the necessary moisture. The syringe is a fine thing, but it is possible to make too much of it. As yet no spider, &c., has made its appearance.

ORNAMENTAL DEPARTMENT.

Were we to detail the minutiae of the week, we would require an almanack. Proceeded with rolling, mowing, and machining lawn. Planted groups of beds as we got opportunity, preparing the beds beforehand, as alluded to some weeks ago, a matter of more importance than early planting. As yet have watered but little, but as the soil is now pretty warm proceeded with loosening the surface with a small Dutch hoe, or the points of a fork. Would mulch Calceolarias if we had the material ready. Tied up herbaceous plants needing that attention. Fine Auriculas and Polyanthus should now have the advantage of an open shaded place on the north side of a wall. Drip is their abomination. Carnations and Pinks need securing neatly. Removed most of the Cinerarias from conservatory, and set part on a north border, on a little fine soil, where they can self-sow themselves. Sowed also some pans of the best for early flowering. These plants will also flourish all the summer planted out on a north border. To obtain early plants of favourite kinds, a good plan is to cut them down, water well, and then plant out in a shady place. They will then throw up lots of strong suckers, which can be divided separately. Azaleas sadly want attention to cutting off all the old flowers, seeds, &c., and giving them a good washing. They ought now to have a house to themselves, so as to give them plenty of heat and moisture to finish their growth. It is thus that commercial establishments can beat the small gardener. They have a suitable place for everything. We often have to make one house answer for everything, and yet it is thought that everything should be first-rate. Vinerias are capital places as makeshifts for these purposes; but then if a single thrips should be on the Azaleas you will rue placing them in your vinery, and so the contest goes on. Those that were forced will now want more light, and air, and coolness to firmly set their buds. Moved young Fuchsias into cooler places. Potted lots of Feathered Cockscobs, Balsams, fine-foliaged plants, and gave water and shade to Ferns, &c. To have *Caladiums* in fine colour we find they should never be exposed to direct sunlight. No syringing should be given them unless the water is pure and clear. We find that with our clearest water, unless filtered, we require to sponge them; a sediment so soon forms, and this disfigures the leaves. Water, heat, and plenty of pot-room are their delight. Whilst growing they may pretty well be treated as a marsh plant. In their younger state, especially, they dearly delight in bottom heat. But all plants that like heat will also benefit by bottom heat. The most striking

results are accomplished by its help. No great thing can be made of the old-fashioned Cockscob without its aid at the earliest stages. Even flower-beds do all the better in proportion to the amount of heat from sunbeams stored up in them before the foliage keeps the heat out.—B. F.

TRADE CATALOGUE RECEIVED.

James Backhouse & Son, York.—Catalogue of Stove, Greenhouse, and Bedding Plants, Ferns, Alpines, &c.

COVENT GARDEN MARKET.—JUNE 10.

Supplies continue very plentiful. Strawberries from the open ground have come in in greater quantity; and of new Potatoes heavy consignments have come to hand from Cornwall and abroad. Of old ones there is yet a very heavy stock, which day by day becomes more unsaleable.

TO CORRESPONDENTS.

\* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

SEEDLING FUCHSIA (*George Benstead*).—A very fair light-sepaled variety with purplish corolla, but in the state in which it reached us no especial merit was discernible.

ROSE (*J. C. C.*).—It is, we believe, a Noisette Rose, and called Ophir; but the petals were all shed.

WORMS (*A Subscriber, Brighton*).—The common earth-worm is not injurious. Its casts disfigure the lawn. Lime-water, poured plentifully upon any spot, will effectually banish them from it.

FROTH INSECT (*Robert Proctor*).—It is so-called popularly, as it also is "Cuckoo-spit" and "Froth-hopper." Entomologists have named it *Tetigonia spumaria*. It is injurious to plants by extracting their sap. The froth is the insect's excrement. The quickest mode of destroying the insect is by the finger and thumb, but we think dusting them with Scotch snuff would incommode them.

RHODODENDRONS AT THE ROYAL BOTANIC GARDENS, REGENT'S PARK.—Allow me to correct an error which occurs in your Number of June 6th in your report of my Rhododendrons now exhibiting at the Regent's Park. You commence your notice "The Knap Hill plants at the Regent's Park," instead of which it ought to have been "The Bagshot plants, &c."—JOHN WATERER.

INSECTS ON CHERRY AND CURRANT TREES (*An Amateur Gardener*).—If they are aphides syringe them with tobacco water.

**EARLY PEAS (R. H. Poynter).**—The Peas we received from you May 28th, and which were selling in Taunton Market at 2s. 6d. per peck, were the earliest and best grown out of doors that we have tasted this year.

**STOPPING VINE SHOOTS (A Young Pruner).**—By allowing the terminal bud to produce three leaves you will repair a great portion of the injury you have done by pinching them back to the first leaf. As soon as the shoot has developed three leaves, pinch out the top of the shoots, the same as described in No. 218. As the Grapes are not in flower they will not be likely to receive so much injury as they otherwise would have done. By preserving the extra leaf above the bunch you will make up for the loss of the principal leaf that has been destroyed.

**TREATMENT OF ESPALIER PEAR TREE (Idem).**—As the Pear tree is making abundance of shoots, it is evident the roots are well at work. You may, therefore, treat it in a similar way to young trees as regards thinning the shoots and training, &c. Put plenty of litter about the tree, to prevent the drying sun and wind reaching the roots. We hope you have not planted it too deep. We strongly advocate planting all kinds of fruit trees as near the surface as possible. If planted deep you had better lift it in the autumn. It will do the tree good, by causing it to make double the quantity of fibrous roots.

**SOWING CUCUMBERS—TWELVE FUCHSIAS—PEAS FOR AUGUST AND SEPTEMBER (J. B.).**—Cucumbers from seed sown now would, if well attended to, come into use at the end of August, and bear until late if the bed were lined. *Sion House Improved* is a good late Cucumber, *Lord Kenyon* and *Kirkles Hall Defiance* are large and good. Fuchsias with white sepals: *Queen of Beauties*, *Minnie Banks*, *Schiller*, *Bridesmaid*, *Gipsy Girl*, and *Guiding Star*. If you mean by white Fuchsias those with white corollas, then *White Lady*, *Sanspareil*, *Bianca*, *Marie Cornelissen*, and *Henry Abts*. The best red: *Constellation*, *Comet*, *Marvellous*, *Universal*, *Cloth of Gold*, and *Shakespeare*. The best Peas to sow to come in in August and September are *Hair's Dwarf Mammoth*, *British Queen*, *Ne Plus Ultra*, and *Lord Raglan*, which should all be sown from fourteen to sixteen weeks before they are expected to come into use. *Bishop's Long-podded*, *Barbidge's Eclipse*, and others of the second early Peas may be sown now, and they will come in in twelve or fourteen weeks. The others may also be sown, but they will not come in at the time named.

**Book (M. A.).**—Bentham's "Handbook of the British Flora," will aid you. Its price is £3 10s.

**MANURING ROSES (H. J. F.).**—Mulching is not manuring. It is putting long dung or cocoa-nut fibre refuse on the soil's surface to keep it moist. Guano forms a liquid manure quite inoffensive, and you can have the guano in half-crown tins at our office.

**ERRORS.**—At p. 433, col. 2, l. 37 from the bottom, the names should be "*Adiantum capillus-Veneris*, *Asplenium marinum*, and *A. trichomanes*."

**PLANTING THE WATER LILY (J. W.).**—We consider April a good time to plant the *Nymphæas* when they are about to grow. We have planted from March to September, simply fastening a stone to the thick fleshy root, and then lowering this at the place desired. In this case the bottom was muddy clay. Where there was little mud we have fastened them to a thick soil with wire, and then lowered them at the place desired. Sometimes we have put them into shallow wide pots, fastening the thick fleshy root to a large stone placed on the pot, and also filled a shallow hamper with strong clay soil using the stone to fasten the root to, as in the case of a pot, and lowered these where wanted. All answered well. The greatest fault in planting is doing so in too shallow water. It should not be less than 1 foot 6 inches, nor more than 3 feet deep.

**RAINFALL (R. Asquith).**—1858 was a drier year than 1864; the total rainfall in that year at Chiswick was 15.78 inches, whilst the amount which fell in 1864 was 18.86 inches, or more than an inch of excess over the quantity registered in 1858.

**PANSIES DECAYING (A Lady Subscriber, Kilkenny).**—We think you have rather overdone them by planting them in old cow-dung and sand. If there is danger of losing the whole take the plants up and divide them into bits, and plant them in a shady place in light sandy loam until they recover themselves, and then you may plant out into richer soil. If you dislike this trouble, water with lime water.

**GARDENER EMIGRATING (Gardener, Limerick).**—We never accept the responsibility of recommending any place as desirable to emigrate to. Too much depends upon the emigrant's acquisitions and constitution, and of these we know nothing.

**PACKING GRAPES (A. B.).**—Have a box made 5 inches deep, and not more than 2 feet long, and 10 or 11 inches wide; put some tissue paper in the bottom, then place the box sloping before you. With the shoulders towards each side lay in the bunches in two rows, and do not place anything between them. When the box has been filled to the top lay in bunches up the centre, the shoulders of each towards the bottom, till the box is full; cover the whole with tissue paper, and on the lid of the box place a printed slip in large letters, "Hothouse Grapes, with special care." This is the advice of a first-rate fruiterer in Covent Garden Market. You can have the index for the volume by sending your direction and two postage stamps.

**BRAIN CORAL—PETRIFIED MOSS.**—"J. L." would be very much obliged if "E. B.," who wrote "Fern Habits" in our Journal, would state where to get "brain coral," also where "petrified moss" is to be had.

**NAMES OF PLANTS (F.).**—It is *Eriophorum angustifolium*, or *Narrow-leaved Cotton Grass*. Country people use it for stuffing pillows, but the silky down becomes very brittle when quite dry. (*T. T. Chesterfield*).—Your evergreen shrub is *Kalmia latifolia*, a native of North America, and quite hardy.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending June 10th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THE BATH AND WEST OF ENGLAND POULTRY SHOW.—JUNE 5-9TH.

THE annual meeting of this Society invariably enlists the warmest interest of those individuals who make the breeding of poultry at once a profitable and pleasing occupation. This year the Show took place at Hereford, and the attendance of visitors proved most satisfactory. One great feature favourable to the popularity of the Bath and West of England Society arises from the fact, that at this Show it is that the early chickens of the year first come into competition. To obtain a mastery on an occasion like this is, therefore, much coveted by our principal breeders, as present success is looked forward to as the herald of ready sale for all superfluous stock from the yards obtaining premiums at the Bath and West of England Exhibition, and at prices also the most remunerative to their respective owners. For these reasons alone poultry-breeders always look forward with great interest to the classes for chickens, and winning-pens are not unfrequently claimed at sums their owners had considered altogether prohibitory of sale. We know several instances have occurred in which chickens that have been thus claimed have secured the premiums at almost every show at which they have subsequently com-

peted until late in the season, when, as an inevitable consequence, they have been at length compelled to succumb to fresh rivals, whose powers have hitherto been uninjured by travelling and close confinement.

The general arrangements were most satisfactory, both as regards the poultry and also the Pigeons. They were exhibited all on one tier about breast high, excepting the Turkeys, Ducks, Geese, and Guinea-fowls. These latter species had commodious pens allotted to them on the grass, and the health and appearance of these birds proved this new arrangement a good one, and a decided improvement on previous plans. The area of the two tents, which were excellently ventilated, gave the most ample room for easy inspection, and the great numbers of visitors constantly passing through the poultry tents proved that at least there was no falling off as to popularity in respect to poultry, nor did the Pigeons appear less attractive than heretofore. It is almost needless to add that the comfort and well-being of the whole was as diligently seen to as could be desired; nor do we remember any show in which so few indifferent specimens were exhibited, and the condition of the birds generally was perfection also, so much so that not a solitary instance of ill-health could be met with. Singularly enough the entry of Spanish fowls nearly doubled as to number any other class in the Exhibition, and the quality of these birds throughout was most meritorious.

The Spanish Silver Cup was taken by a very first-class

pen from Mr. Jones, of Clifton, Viscountess Holmesdale's well-known and excellent pen being a very good second, and Mr. Beldon, of Yorkshire, being but little in the rear as third prize-taker. It is long since so superior and regular a class of Spanish has been exhibited; and the first-prize Sweepstakes Spanish cock (Viscountess Holmesdale's), is also well worthy of especial mention. We cannot but congratulate the Bath and West of England Society on this prominent improvement on former meetings in so aristocratic a breed of fowls.

The class for "Coloured" *Dorkings* proved one of the most important in the Show. Here pen after pen was of the highest order, and consequently the competition was general throughout a strong class. As many of our poultry fanciers might anticipate, Viscountess Holmesdale exhibited some birds that place most of her ladyship's rivals far in the rear. Captain Lane, of Bracknell, Berkshire, exhibited a wonderfully well-feathered, well-matched, and equally well-grown pen, so far as size only is considered; but it should always be remembered that natural malformation of the legs is quite inadmissible. In this case one hen was fearfully "knock-kneed," and presented a striking instance of deformity, arising, most probably, from over-feeding as a chicken, combined with want of sufficient exercise whilst only a few weeks old. We mention this, as a hint to all breeders of heavy-weighted chickens, to give every facility for exercise during the first few weeks, and afterwards to increase weight by excessive feeding when the bone becomes more hardened and matured. It is thus that overmuch kindness and anxiety to indulge the chickens of large breeds oftentimes ends in self-wrought disappointment; and we may add that our own experience proves, beyond question, that parents whose formation is thus imperfect not unfrequently have even wry-backed offspring.

In *Cochins* we were not prepared for so perfect a display, and we hear a great rivalry had existed to gain position at the Hereford meeting. The competitors were evidently not resting on their oars, but looking as alike as possible; and, after absenting himself from exhibiting for some two years or more past, Mr. H. Tomlinson, of Birmingham, again took his old position at the head of the prize list with a pen of colossal Buffs, as neat as they were excellent. Captain Heaton, of Manchester, pushed in closely for a second place, and Mr. Stephens, of Walsall, was not by any means a bad third. We were glad to see so plucky an exhibitor as Mr. Zurhorst, of Dublin, rewarded by success in wonderfully well-shown White *Cochins*, Single (Buff) Sweepstakes *Cochin* cock, an exceedingly neat specimen; and a pen of immense first-prize *Turkeys*, that would excite the fondest anticipations of any gourmand who happened to cast eyes on them at the Bath and West of England Show. Mr. Boyle, also of the Sister Isle, exhibited a first-prize pen of *Geese* that, as was jocosely observed by a visitor, "seemed made expressly for a working man with a numerous family." Visitors thronged this pen constantly, and they proved a feature of the Show. Nor were Mr. Boyle's *Brahmas* less conspicuous for merit, in a most spirited competition. We repeat we were glad to see old Ireland pulling up so strongly as she did in many of the most useful breeds; for this inevitably must tend to still greater attention and improvement, making John Bull look to his colours in the friendly tournaments of our poultry exhibitions.

In *Game* fowls the show was very strong; and although Mr. Fletcher, of Stoneclough, near Manchester, took, without exception, every first prize, and thus of necessity the silver cup for the best pen of *Game* fowls exhibited, it must not be supposed it was not well contested, or that extraordinary merit was wanting elsewhere. The *Hamburgs* were very good, as were also the *Poland* fowls; and the *Bantams* were equally praiseworthy. We regretted to find that a case occurred of birds being exhibited as true chickens of 1865, that evidently were first ushered into life considerably anterior to Christmas last. They were very properly disqualified by the Judges; and we hope that in every case where the like imposition is attempted, the same determination to put a stop to such practices will be at once adopted. It is quite time that autumn-hatched chickens were put down when shown as spring birds, and the custom of so doing is most reprehensible, and has been in somewhat general practice until some parties seem to consider its universality its perfect excuse. It is quite time it were

done away with, and none but spring chickens held admissible.

In the Extra Variety class there was a good entry, a capital pen of Malays taking the lead, a pen of perfect Silky fowls second position, and a pen of excellent White Spanish fowls, exhibited by Mr. F. B. Pitman, the third prize. So great was the competition, however, that an extra third prize was here awarded to Mr. Beldon's White *Polands*, a very interesting group, and well shown.

In the *Pigeons* the competition was not only very keen indeed, but such as would render any meeting popular. Mr. A. Pintoleite, of Manchester, was the fortunate winner of the silver cup; and Mr. H. Yardley, of Birmingham, of the Society's silver medal as a second extra prize for *Pigeons*. The whole of the *Pigeon* classes were unusually good.

The weather was very fine, and the attendance a perfect success.

**SPANISH.**—First and Cup, E. Jones, Clifton. Second, Viscountess Holmesdale, Linton Park, Kent. Third, H. Beldon, Bingley, Yorkshire. Highly Commended, R. Wright, London; Capt. Heaton, Manchester; T. Bamfield, Clifton; T. Smith, Walsall.

**DORKINGS (Coloured).**—First, Cup, and Third, Viscountess Holmesdale. Second, J. K. Fowler, Aylesbury. Commended, J. Norman, Pezshore.

**DORKINGS (White).**—First and Second, H. Lingwood, Needham Market, Suffolk. Third, Rev. G. F. Hodson, North Petherton, Bridgewater.

**COCHIN-CHINA (Coloured).**—First, H. Tomlinson, Birmingham. Second, Capt. Heaton, Manchester. Third, J. Stephens, Walsall. Commended, H. Bates, Birmingham; H. Griffiths, Worcester.

**COCHIN-CHINA (White).**—First, F. W. Zurhorst, Donnybrook, Dublin. Second, W. Dawson, Hopton, Mirfield, Yorkshire. Third, R. Chase, Balsall Heath, Birmingham. Commended, G. Lamb, Compton, Wolverhampton.

**GAME (White and Piles).**—First, Cup, and Second, J. Fletcher, Stoneclough, Manchester. Third, S. Matthew, Stowmarket, Suffolk. Commended, T. Burgess, Whitchurch, Salop.

**GAME (Black-breasted and other Reds).**—First and Second, J. Fletcher, Manchester. Third, A. B. Dyas, Madeley, Salop. Highly Commended, H. Adney, Colliumpton; Rev. G. S. Cruwys, Tiverton.

**GAME (Duckwing and other Greys and Blues).**—First, J. Fletcher, Manchester. Second, Rev. G. S. Cruwys, Tiverton. Third, S. Matthew, Stowmarket, Suffolk.

**BRAMA POOTRA.**—First, R. W. Boyle, Dundrum, Dublin. Second, H. Lacy, Hebdon Bridge. Third, Mrs. Hargreaves, Reading. Highly Commended, J. Marfell, Hereford; E. Pigeon, Exeter; J. Hinton, Hiaton, Bath; J. K. Fowler, Aylesbury.

**HAMBURGERS (Golden-pencilled).**—First, F. Pittis, jun., Newport, Isle of Wight. Second, J. E. Price, Hereford. Third, J. S. Maggs, Tetbury.

**HAMBURGERS (Silver-pencilled).**—First, Viscountess Holmesdale. Second, J. Holland, Worcester. Third, H. Beldon, Bingley.

**HAMBURGERS (Golden-spangled).**—First, A. K. Wood, Kendal. Second, W. Bayliss, Walsall. Third, T. Davies, Birmingham. Highly Commended, T. Davies; H. Beldon, Bingley.

**HAMBURGERS (Silver-spangled).**—First, H. Beldon, Bingley. Second, G. Whitcombe, Gloucester. Third, T. Davies, Newport, Monmouthshire. Highly Commended, W. Bowley, Cirencester.

**POLANDS (Black with White Crests).**—First and Third, H. Carter, Holmfirth, Yorkshire. Second and Highly Commended, T. P. Edwards, Lyndhurst.

**POLANDS (Gold or Silver).**—First and Second, H. Beldon, Bingley. Third, Mrs. Blay, Worcester.

**ANY OTHER VARIETY.**—First, Rev. A. G. Brooke, Ruyton XI. Towns, Salop (Malays). Second, R. H. Nicholas, Newport, Monmouthshire (Chinese Silks). Third, F. B. Pitman, Taunton (White Spanish). Extra Third, H. Beldon, Bingley. Highly Commended, E. Pigeon, Exeter (La Flèche). Commended, Mrs. Haig, Lichfield (Maggie Tantans); R. Tate, Leeds (Black Hamburgs).

**DORKING CHICKEN.**—First, Mrs. Barter, Plymouth. Second, Rev. G. F. Hodson, Bridgewater. Highly Commended, Mrs. Dunn, Hungerford.

**GAME CHICKENS.**—Second, H. Adney, Colliumpton. First Prize withheld.

**COCHIN-CHINA CHICKENS.**—First, J. K. Rodbard, Wrington, Somerset. Second, Rev. F. Taylor, Kirkby Lensdale, Westmoreland. Highly Commended, F. W. Rust, Hastings; P. Cartwright, Oswestry. Commended, J. Shorthose, Newcastle-on-Tyne.

**SWEETSTAKES.—GAME.**—First and Second, J. Fletcher, Manchester. Third, F. Statter, Manchester. Commended, Rev. G. S. Cruwys, Tiverton.

**SWEETSTAKES.—SPANISH.**—First, Viscountess Holmesdale. Second, R. Wright, London. Third, J. R. Rodbard, Wrington, Somerset.

**SWEETSTAKES.—DORKING.**—First, F. Statter, Manchester. Second, Viscountess Holmesdale. Third, C. Smith, Salisbury.

**SWEETSTAKES.—COCHIN-CHINA.**—First, F. W. Zurhorst, Dublin. Second, E. A. Tudman, Whitchurch, Salop. Third, J. E. Price, Hereford. Highly Commended, W. Curwain, Cambridge. Commended, W. Bowley, Cirencester.

**SWEETSTAKES.—GAME BANTAMS.**—First, E. Cambridge, Bristol. Second, S. Lang, jun., Bristol. Third, G. Manning, Springfield, Essex.

**BANTAMS (Gold-laced).**—First and Cup, Rev. G. S. Cruwys, Tiverton. Second Prize withheld.

**BANTAMS (Silver-laced).**—First, Rev. G. S. Cruwys. Second and Commended, E. Jones, Clifton.

**BANTAMS (White and Black).**—First, Rev. G. S. Cruwys. Second and Highly Commended, T. Davies, Newport, Monmouthshire. Commended, W. Draycott, Leicester.

**BANTAMS (Any other Variety).**—First, S. Ward, Chesterfield (Game). Second, J. Fletcher, Manchester (Game).

**DUCKS (Aylesbury).**—First and Cup, J. K. Fowler, Aylesbury. Second, W. C. N. Hughes D'Alais, Reading.

**DUCKS (Rouen).**—First, A. Woods, Liverpool. Second, J. R. Rodbard, Wrington, Somerset.

**DUCKS (Any other Variety).**—First, T. H. D. Bayly, Biggleswade, Beds. Second, T. G. Harrison, Hull (Brown Call). Commended, J. W. Kelleway, Merston, Isle of Wight (Black East Indian).

**GESE.**—First, R. W. Boyle, Dublin. Second, J. K. Fowler, Aylesbury.  
**TURKEYS.**—First, F. W. Zurlhorst, Dublin. Second, C. Edwards, Wington, Somerset. Highly Commended, J. Norman, Pershore; J. K. Fowler, Aylesbury. Commended, Mrs. Dunn, Inglewood, Hungerford.

**GUINEA FOWLS.**—First, Miss Worthote, Exeter. Second, O. A. Young, Driffield, Yorkshire. Commended, Rev. M. Amphlett, Evesham; R. Tate, Leeds.

#### PIGEONS.

**CARRIERS.**—First and Second, A. Pintoleite, Manchester.  
**TUMBLERS (Almond).**—First and Second, A. Pintoleite, Manchester.  
**TOMBLERS (Any other Variety).**—First, A. Pintoleite. Second, J. Percivall, Peckham. Commended, J. R. Robinson, Sunderland.  
**POWTERS.**—First, H. Yardley, Birmingham. Second, A. Pintoleite, Highly Commended, J. R. Robinson, Sunderland.  
**RUNTS.**—First, E. Pigeon, Lymptone, Exeter. Second, T. D. Green, Saffron Walden, Essex.  
**JACOBINS.**—First, J. Percivall, Peckham. Second, C. Bulpin, Bridgewater.

**FANTAILS.**—First, J. R. Robinson, Sunderland. Second, H. Yardley, Birmingham.

**OWLS.**—First and Second, A. Pintoleite. Highly Commended, E. Pigeon; H. Yardley.

**TRUMPETERS.**—First, J. R. Robinson. Second, C. Bulpin, Bridgewater.  
**BARBS.**—First, J. R. Robinson. Second, A. Pintoleite.

**TURBITS.**—First, H. Yardley. Second and Commended, J. R. Robinson.  
**NUNS.**—First and Second, Rev. A. G. Brooke, Ruyton XI. Towns, Salop.

**DRAGONS.**—First and Highly Commended, H. Yardley. Second, J. Percivall, Peckham.

**ARCHANGELS.**—First and Second, H. Yardley.  
**ANY OTHER NEW OR DISTINCT VARIETY.**—First, Extra Second, and Highly Commended, A. Pintoleite. Second, H. Yardley.

**PIGEON CUP,** won by A. Pintoleite with Five First and Six Second Prizes.

Mr. Charles Ballance, of Stanley House, Lower Clapton, and Mr. Edward Hewitt, of Eden Cottage, Sparkbrook, Birmingham, were Judges for poultry; and Dr. Cotile, of Cheltenham, and Mr. Harrison Weir, of London, were the Arbitrators for Pigeons.

### BRENTWOOD EXHIBITION OF POULTRY AND PIGEONS.

It appears that for the last three years the Brentwood Poultry Exhibition has been in abeyance, but we can confidently assert that the whole of our experience does not call to mind any instance in which the entire collection at any poultry show was so perfect and complete throughout as at Brentwood Show just held. It would be no exaggeration to say that not even a single pen of indifferent birds was exhibited. We know a universal impression prevailed that the Bath and West of England Show at Hereford would prove a great drawback to the Brentwood meeting, but the results proved this altogether a misapprehension, although held simultaneously.

No doubt a very great assistance to the Brentwood entries arose from the fact that this Show continued open only a single day, whilst the one held at Hereford necessitated the birds being away from home for a week or more. This, combined with the fact that the premiums were about equal in point of money value, was all in favour of short imprisonment. The entries embraced most of our local poultry celebrities, even Ireland, Scotland, and most of our English counties being well represented. We may confidently add that we have seen exhibitions rejoicing in even a thousand entries not containing so many good birds as did the two hundred pens or so at Brentwood. Where all classes were so excellent it would be a most invidious task to enter into particularities, and we therefore refer our readers to the appended prize list, in which will be found very few blanks from any reputed yard among our poultry breeders.

We must not, however, conclude without a recognition of the excellent management of the Committee of everything connected with the Show, and rejoiced to add, that the weather being propitious, a capital attendance ensued. The funds, therefore, are proportionably augmented. The birds were safely returned immediately after the Show without mistake or injury.

**DORKINGS (Coloured).**—First, Dr. Campbell, Brentwood. Second, G. Griggs, Romford. Third, H. Lingwood, Needham Market. Highly Commended, G. Griggs; Sir St. G. Gore, Bart., Wicksouth; R. B. Postans; H. Lingwood.

**DORKINGS (White or Silver Grey).**—First and Second, Dr. Campbell, Brentwood.

**SPANISH.**—First, J. R. Rodbard, Wington, Bristol. Second, A. Heath, Calne, Wilts. Third, T. J. Bailey, Brentwood. Highly Commended, R. B. Postans, Brentwood. Commended, Mrs. Pattison, Maldon, Essex.

**GAME (Black-breasted and other Reds).**—First and Second, S. Matthew, Stowmarket. Highly Commended, Hon. H. W. Fitzwilliam, Rotherham; Rev. F. Watson, Kelvedon, Essex. Commended, Sir St. G. Gore, Bart., Wicksouth.

**GAME (Any other Colour).**—First, S. Matthew, Stowmarket. Second, Sir St. G. Gore, Bart. Highly Commended, S. Matthew.

**COCHINS (Buff).**—First, P. W. Rust, Hastings. Second, H. Lingwood, Needham Market. Highly Commended, W. Mattingly, Chelmsford; H. Bates, Birmingham.

**COCHINS (Any other colour).**—First, R. J. Wood, Chorley. Second, F. W. Zurlhorst, Dublin. Highly Commended, W. Dawson, Yorkshire; Mrs. Seamons, Hartwell, Aylesbury.

**BRAHMAS (Dark or Light).**—First, J. Hinton, Hinton, near Bath. Second, J. Pares, Chertsey.

**HAMBURGS (Silver-pencilled).**—First, Sir St. G. Gore, Bart., Wicksouth. Second, T. J. Saltmarsh, Chelmsford. Highly Commended, D. Illingworth, Yorkshire.

**HAMBURGS (Gold-pencilled).**—First, Sir St. G. Gore, Bart. Second, F. Pittis, jun., Isle of Wight. Highly Commended, F. Pittis. Commended, Rev. T. L. Fellowes, Acle, Norfolk.

**HAMBURGS (Gold-spangled).**—First, Sir St. G. Gore, Bart., Wicksouth. Second, A. K. Wood, Westmoreland. Commended, H. Snushall, Wisbeach.

**HAMBURGS (Silver-spangled).**—First, A. K. Wood, Westmoreland. Second, Sir St. G. Gore, Bart. Highly Commended, Rev. T. L. Fellowes, Norfolk.

**POLISH (Any colour).**—First, T. P. Edwards, Lyndhurst. Second, J. Hinton, Hinton, near Bath. Commended, T. P. Edwards.

**GAME BANTAMS (Black-breasted and other Reds).**—First, Sir St. G. Gore, Bart. Second, Rev. G. Raynor, Brentwood. Highly Commended, G. Manning, Essex; J. Munn, Manchester. Commended, G. Manning.

**GAME BANTAMS (Any other colour).**—First, Rev. G. Raynor, Brentwood. Second, Withheld.

**BANTAMS (Black or White).**—First, F. Pittis, jun., Isle of Wight. Second, Sir St. G. Gore, Bart. Highly Commended, Mrs. Hill, Warley, Essex.

**BANTAMS (Any other variety).**—First, G. Manning, Essex. Second, G. Griggs, Romford.

**ANY OTHER DISTINCT VARIETY.**—First, J. Hinton, Hinton, near Bath. Second, Withheld.

**TURKEYS (Any colour).**—First, J. S. Lescher, South Weald. Second, C. Squier, Essex.

**GESE (Any colour).**—First, R. B. Postans, Brentwood. Second, J. S. Lescher, South Weald.

**DUCES (White).**—First and Second, Mrs. Seamons, Aylesbury. Commended, C. Bamford, Cambridge.

**DUCES (Rouen).**—First, C. Punchard, Suffolk. Second, Sir St. G. Gore, Bart.

**SWEPESTAKES.—Game Cocks (Any colour).**—First, Sir St. G. Gore, Bart. Second, W. Rogers, Suffolk. Third, H. J. Bush, Brentwood. Highly Commended, S. Matthew, Stowmarket.

**Game Bantam Cocks (Any colour).**—First, Rev. G. Raynor, Brentwood. Second, Dr. Campbell. Third, G. Manning, Essex. Highly Commended, T. J. Saltmarsh, Chelmsford.

**PIGEONS.—Carriers (Any colour).**—First, H. Yardley, Birmingham. Second, W. Massey, Yorkshire. Highly Commended, E. E. M. Royds, Ashby-de-la-Zouch.

**Powters (Any colour).**—First, F. Disney, Essex. Second, H. Yardley, Birmingham. Highly Commended, E. E. M. Royds, Ashby-de-la-Zouch.

**Almond Tumblers.**—First, W. Massey, Yorkshire. Second, H. Yardley, Birmingham. *Any other Variety.*—First, H. Yardley, Birmingham. Second, H. W. Hall, Croydon. Highly Commended, E. E. M. Royds; H. Snushall, Wisbeach.

**PHEASANTS.**—Prizes, J. Riley.

**CANARIES.**—Prize, J. Cook.

**RABBITS.—Lop-eared Buck.**—Prize, E. E. M. Royds, Ashby-de-la-Zouch.

**Lop-eared Doe.**—Prize, E. Lawrence, Essex. *Heaviest of any kind.*—Prize, E. E. M. Royds. *Extra.*—Highly Commended, Miss N. Hamilton.

Mr. Edward Hewitt, of Sparkbrook, Birmingham, officiated as Arbitrator.

### PIGEONS AND ROOKS.

"HAMBURGH's" letter has set me thinking and inquiring further into the subject of the supposed alarm felt by Pigeons at the nearness of Rooks, and the consequent desertion of the Pigeons from their houses. My Pigeons, Tumblers and Powters, show no such alarm, not even yesterday, when we shot upwards of a hundred Rooks. My neighbour at the farm, who lives as near to another part of the rookery, always has a good number of dove-house Pigeons, in spite of an annual domestic shooting-match. Then, six miles from me is a rookery remarkable for being established on trees of very low growth. It is on one side of the house, and on the other side many Pigeons are kept for table purposes. Here, then, are three cases in point on my side of the question. What say any other of our writers or readers? From all birds of the hawk tribe Pigeons would instinctively flee; but I doubt much if they would flee from Rooks, who would neither fight them nor eat them.

Then, in regard to pole-houses. They are, if well made, undoubtedly very pretty objects, and may also be constructed on a roomy plan; but I think if "HAMBURGH" gave the Pigeons the choice of a loft or a pole-house he would find the loft exclusively used as a domicile. Some years ago I was consulted by a lady very fond of her flight of Jacobins. She was building new stable-offices, and wished to place her Pigeons in comfortable quarters, but could not give them a loft. On my suggestion she had a series of holes made in the brickwork of the south front of her hayloft, and landing-boards placed outside of a good depth and well-divided. Inside I planned, in deal, lockers of the depth from the front

of 1½ to 2 feet, and each opening at the back like a cupboard, the back being in fact a number of doors. This arrangement enabled her to catch her Pigeons, inspect the nests, and have all cleaned out easily, besides making a safe and comfortable home for the birds, taking up little room. I usually see landing-boards not half so wide as they ought to be, for Pigeons want a good broad space upon which to alight, coo upon, and sun themselves—a mere ledge is a miserable shift, and sometimes the Pigeons have not height either. I have also found that the owners have been unable to paint their pole-houses or repair them lest they should drive away the birds; yet certainly they ought to be painted every spring. Would any of our lady readers who draw well give us a sketch of a pretty and commodious house on a pole?—**WILTSHIRE RECTOR.**

### HIVES WITH ENTRANCES AT TOP.

WHEN I saw the letter at page 352 with my name in it I was as much surprised as my Renfrewshire friend must have been amused, and I am glad he has given me this opportunity of rectifying a mistake—a mistake I had not the least intention should be made—viz., that of the letter appearing in my name instead of that of Mr. C. Williams, for whom I wrote it. Not but that I should have been very proud of the honour of bringing before the public the utility of this kind of hive; the advantage over the entrance at bottom I leave for any apiarian to judge.

In the first place, the bees entering their hives at top invariably enjoy good health, as they have a constant supply of fresh air penetrating thoroughly among them without a cold draught on the brood, as the air must have the chill taken off it after passing through the bulk of bees before it reaches the bottom. When the entrance is at the bottom the brood is entirely exposed to the cold air, without the same chances of its becoming warm, for it can never ascend so long as the air above it is warmer. 2ndly, The honey keeps better in the cold dry air. 3rdly, The bees have not so far to carry it, besides having the advantage of carrying it down-hill instead of up. 4thly, More bees can be spared to collect when a swarm is put into a new hive. 5thly, After filling the stock hive they have only half the distance to carry the honey to the supers. 6thly, Bees kept in these hives never suffer from damp, which is the plague of an apiary, as it invariably finds egress in the shape of steam. When the entrance is at the bottom the vapour condenses on the sides, and runs out in streams of water, especially when the hives are very strong, and the nights are a little cool. Huish, in his work on bees, published in 1817, page 72, tells us that hives with a flat top for storifying are on an erroneous plan, and that it is the rock on which the partisans of the storifying system have been wrecked, because, he says, "The bees when in health never vent any excrement in the hive, and being never benumbed, they continually consume their food, and, consequently, evacuate by a considerable perspiration, which rises in vapour to the top of the hive, and in winter these vapours are almost continual, and it is proper they should be carried off without falling upon the bees." Again, at page 74, he asks, "What is the most common cause of the loss of the hives during winter?" "I do not speak of hunger, for that is the fault of the proprietor, but I maintain it is the moisture of the combs, occasioned by the fall of the water collected at the top of the hives, which are flat; it is also the fall of these waters on the bees which, stopping their perspiration, sours and corrupts the matters which are in their body, causing the dysentery, and carrying infection and death through the whole community."

How far these vapours tend to promote dysentery I cannot say, as Mr. Williams assures me that since he has invented this hive he has never had any disease in his apiary, or lost a single hive, although he has kept the same from seven to eighteen years before disposing of them. I have one that I purchased from him that is now upwards of twenty years old; and with all due deference to the critical acumen of the "RENFREWESHIRE BEE-KEEPER," I am still obstinate enough to maintain my original opinion; and without more substantial objections than he brings forward to convince me of the uselessness of entrances at the top, I never intend

to keep a hive with the entrance at bottom in my apiary a season longer than I can possibly help. I must say the trial he gave them was certainly a very good one, for he could not have made their entrance much nearer the top, situated as he was, without making them go down the chimney; and the result of his experiment was equally satisfactory, as he tells us in one breath the plan succeeded so well, that the very first season he took from two hives a half-hundredweight of beautiful honey, and almost in the next contradicts himself, and tells us that he most reluctantly abandoned bee-keeping in high latitudes, under the impression that hives with entrances at the top have to the inexperienced only novelty to recommend them. I am glad he is candid enough to tell us it was his inexperience in dealing with them in that position that led him to abandon them; at the same time he should not have complained of his tools.

Before I conclude, I feel that I am bound to answer the only objection to Mr. Williams's hives—viz., the difficulty of the bees cleaning them; and in reply would ask, whether at any season of the year there is more carried into the hive than out of it? And I have no hesitation in saying that there is five hundred times more carried into the hive than has to be carried out, even if the bottoms are never cleaned. Then supposing the entrance to be at the bottom, the bees have five hundred loads to carry up-hill to one they carry down or on the level. If, on the contrary, the entrance is at the top, they will have five hundred loads to carry down-hill to one up, and the advantage then is very manifest. When an apiarian cleans the bottom board four times a-year the bees will have very little to do in that way. I trust I have shown some few of the advantages of this hive without displaying any acrimony to my Renfrewshire friend.—**HENRY STUTTLE, Kingsland, Shrewsbury.**

### FOUL BROOD INCURABLE BY EXCISION.

IN the detailed report of my experience of "foul brood," in No. 149, I showed how the excision of the entire brood in my stocks signally failed to effect a cure, the disease breaking out in all its virulence in the new-formed portions of comb. These stocks without exception died out during the winter, although well found in store.

With the view of aiding me as much as possible in rebuilding my shipwrecked apiary, "A DEVONSHIRE BEE-KEEPER," in the kindest manner sent me last April twelve months his strongest Ligurian stock, and although it lost upwards of five thousand of its population on the journey, speedily recruited, and appeared quite healthy. With the assistance of abundance of black bees bought in, and new hives, I had by the month of July, in addition to my black stocks, been successful in establishing six fine colonies with most prolific Ligurian queens at their head.

I was quite appalled in the beginning of August to find foul brood unmistakeably present, not only in the original stock, but in four of the young hives. I was successful in effecting a thorough cure of the population of the old stock, by passing them twice through the "purgatorial process," then introducing them into the combs of a good second hive, from which the black bees had been previously removed. The queen bred well at the end of the season, but unfortunately died during the winter. I lost one of the young queens from the continuous confinement necessary to effect a cure, a second from being neglected by the black bees to which I purposed introducing her, and a third from being totally deserted in my absence by her new subjects, while caged, they preferring to transfer their allegiance from the Italian to the black monarch of the adjoining stock, so that this spring found me with only two Ligurian queens, the one presiding over a particularly strong healthy colony, in a set of Stewarton boxes, the other over a square straw frame-hive.

The traces of foul brood in the last-mentioned hive were so slight, that I resolved to let it stand unmolested over the winter in the hope that the long cessation from breeding might tend to alleviate, if not stay, the plague, but finding in the spring the fresh brood grouped all round the suspicious, I feared it might thereby be contaminated, and as already mentioned in my remarks, on "The Opening Sea-

son," in No. 209, I out out the entire brood, good as well as bad, shifting the frames so operated on to one side, and bringing to the centre as many of the white pure combs of the side never bred in. In the month of April I examined the hive, and was mortified to find foul brood still present, I therefore on the 27th of that month, brimstoned the workers, and was fortunate in safely introducing their queen to a good black colony.

My object in writing the above, in addition to establishing that the taint of this disease lurks in the combs of a colony, even after the cessation of breeding during winter, and that it will break out in even the otherwise pure combs in spring, is, that should the opinion of your talented contributor, Mr. Lowe, be unchanged, I would be most happy on receiving his address through the Editors, to present him with the frame-hive above alluded to, in the hope that were he to hive a swarm therein, he might be enabled to study the evolution of the pupæ, and possibly from his thorough scientific acquaintance with the honey bee, throw a flood of light on this singular malady, alike the deepest mystery and most terrible bane to many an apiarian reader of the Journal," as well as to—A RENFREWSHIRE BEE-KEEPER.

NOTES AND QUERIES ABOUT QUEENS.

I HAVE read with interest the account of the death of a queen related by "J. M. W." in page 392. On the 4th of April he said he fed with pieces of honeycomb through the day, a practice which I am sure the initiated would at once see was wrong; but I know it is done by many in our own neighbourhood, even after being warned to desist; and although there is nothing that gives me greater pleasure than to see my neighbours' hives prosper, still in this case I should not be sorry to hear of their losing their whole stock, as it would then give peace to others for miles around. What can be more evident than that his queen, as is too often the case, had been expelled by robbers? At all events there is something mysterious in his case, for from the time of the expulsion of the queen there are only twenty-two days—not sufficient time for a virgin queen to commence egg-laying, taking his own statement that there was drone brood in all stages, which shows there must have been eggs laid from the 4th till the 22nd. Is he sure that it was drone brood, and a different queen from the one he saw on the 4th? I do not think that two mothers would be allowed to live together in the hive, even for a few days, during winter (the longest period I ever knew being fifty hours), which must have been the case if there was a mother ready to lay eggs the same day that the old one was expelled. Besides, queens appear much smaller after death.

Can any of your correspondents say at what age a queen whose impregnation has been retarded will commence egg-laying? I fully intended to have proved it this spring, as I had queens hatched in the beginning of April, and kept them twenty-three days, but I required the bees and had to kill them ere my end was accomplished.—A LANARKSHIRE BEE-KEEPER.

P.S.—May I be allowed to ask Mr. Henry Stuttle what particular merit is in his hive when, as he says, last year was the only fortunate one he has had in getting off clean supers? When such a year presents itself we are in no difficulty in getting clean combs, even in an old hat or such like. If he would take a trip northwards in but an indiffererent year, we could show him something that would dazzle his eyes, and ventilated in a very different manner from the way he describes. I tried the plan he recommends seventeen years ago, and was glad to give it up in seventeen days—nay, I went further, and tried seven different places of entrance.

SPONTANEOUS UNION OF SWARMS.

In the beginning of last week I sent one of Mr. Williams's straw hives with entrance at the top, to a friend of mine, who had promised me one of his first swarms. On Saturday last, May 20th, he had three swarms from three common straw hives; the first one he hived in my hive, and left it in the place they knit; the other two he hived in two common straw hives, also leaving them where they knit, apparently all right, and well satisfied with their quarters; but

in about half an hour after hiving the last swarm, he was informed by one of his family that the bees were swarming again. Upon proceeding to the apiary, he was surprised to see No. 1 swarm leaving its hive, and going straight into my hive very peaceably, and in a very short time they were as comfortable as if there had been only one swarm in the hive. But now comes the most remarkable part of the case. In about an hour afterwards, looking how things were going on, he was much surprised to find that No. 2 swarm had also taken a fancy to my hive, and were migrating with all possible dispatch, and comfortably ensconcing themselves with the two first swarms, making a total of three distinct swarms in my hive, each of which was a very good swarm. The weight of bees including the hive was 23½ lbs. and as the hive weighs 11 lbs., the weight of the bees was 12½ lbs. Such a mass in one hive I have never seen before—in fact, they are so thick in the hive, which is very large, that some cluster on the outside at night, and I am obliged to use the entrance at bottom as well as top.

Not knowing what will be their next proceeding, as in all my experience I have never had, nor known three first swarms joined together, I have taken the liberty of acquainting you with this remarkable event. At present they are working as nicely and as amicably as I have ever seen any bees do, and I should fancy they must fill the hive with comb in the course of three days more, as they appear to work in proportion to their strength.

The address of the gentleman who gave me the bees is Mr. Jones, Borneo Farm, near Shrewsbury.—HENRY STUTTLE, Kingsland, Shrewsbury.

[We shall be glad to know how this monster colony prospers.]

OUR LETTER BOX.

HENS SWALLOWING WITH DIFFICULTY (A. Wood).—Your hens have sore, probably ulcerated, throats, arising from a disordered state of body—change their food. Discontinue all whole corn; give them ground oats, or oatmeal slaked with water, and in an almost liquid state. Instead of vegetables, give them large sods of growing grass, which they will readily eat, earth and all. They will then recover.

HAMBURGS WITH PALE FACES (Idem).—It may be that your Hamburgs are about to moult, having finished their laying. If so, dying combs and pale faces are the natural symptoms and precursors. If that is not the case we advise you to treat them as above.

"A COUNTRY PARSON" will be answered in our next.

HOW TO TELL A COCK FROM A HEN PIGEON (P. A. L.).—In young Pigeons in the nest the larger, thicker-beaked, wider-headed, and wider-winged is considered to be the cock, but they are frequently both of one sex. After they leave the nest, until they are matchable, it is almost impossible to tell. When arrived at maturity the cock is thicker about the beak, head, and neck; he has a bolder look. The hen is narrower, and more slender and timid-looking. As to manner, the cock is more interfering, cooing to all other Pigeons, bowing and sweeping after them with his spread tail. He will clap his wings more as he flies, and sometimes raises them as he stands on the house top.—B. P. B.

BEES WITH EXTRA ANTENNÆ (Bee Friend).—The supposed extra antennæ are, in reality, pollen-masses from some species of orchis which have become firmly attached to the heads of these unfortunate bees by the glutinous secretion at their bases. This singular provision of nature for the fecundation of the blossoms of the orchidaceous tribe of plants was first noticed and fully described by Mr. Charles Darwin in his interesting work on the fertilisation of orchids.

BEES CLUSTERING OUTSIDE THE HIVES (J. C.).—We should at once proceed to make artificial swarms. The simplest and best mode of effecting this operation with stocks in common straw hives was fully described by Mr. Woodbury in No. 161 of our new series.

MOVING BEES (Beriah).—The best mode of preparing bees in a frame-hive for a long journey is by tacking a square of perforated zinc over the top in the place of the crown-board, which latter should be raised half or three-quarters of an inch, and kept in that position by the insertion of four small wooden blocks, screws of extra length being substituted, if necessary, for those in ordinary use. The entrance being also secured with perforated zinc, the floor-board screwed on, and the hive well corded, it will bear removal to almost any distance if not too roughly treated. We should, however, prefer taking it under our own care to entrusting it to the chapter of accidents in the furniture-van.

LONDON MARKETS.—JUNE 12.

POULTRY.

A short supply and a good trade combine to keep up prices. We must, however, look for lower quotations.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 73.1°, and its night temperature 49.4°. The greatest heat was 93° on the 22nd, 1846; and the lowest cold, 35°, on the 23rd, 1851. The greatest fall of rain was 0.72 inch.

THE MODERN PEACH-PRUNER.

No. 11.

THEORY OF LONG PRUNING.

THE object of all pruning is not to increase the vigour of the entire tree, but to control and modify that vigour, and so accelerate and regulate the fruiting period. Pruning, conjointly with appropriate training, claims to be able to add to the longevity of fruit trees. This is effected by balancing the separate parts. More

than this ought not to be expected from any system of pruning. This, to be successful, must be based on an accurate knowledge of the habits of each kind, which knowledge is the result of observation and experience. It is here that the recorded opinions of men eminent in their profession are valuable; for, though the Peach tree adapts itself to many varying conditions of culture, there are certain principles which should be ever kept in mind.

Those who have seen the Peach-orchards of the south of Europe, and of America, know how little care is generally bestowed on them beyond manuring the roots. In these favourable climates standards, three years old are laden with fruit. They bear thus, exhaust themselves, and decay, without more than a casual attention being paid to them. This is culture reduced to its simplest elements; but even in such cases experience has shown the value of some kind of pruning. This, according to Downing, consist in cutting out one-half of the shoots of last year's growth. The crop is diminished by one-half, but the size of the remainder is doubled. In the more northern states espalier training is in vogue, requiring far more care. The attention paid to Peach culture in northern and mid-France equals that required in England. Superb fruit is grown in America in nearly every part, but, in France, only where scientific training is employed; for the standard-grown Peaches of the southern districts are valueless. In England, therefore, it is useless to expect success without labour and skill, and foreigners do well to admire the great results produced under such difficult conditions.

No one can now reasonably doubt the immense boon which the introduction of orchard-houses has been to lovers of the Peach. We, who are conversant with the best productions of foreign climates, know that fruit grown in well-managed orchard-houses is literally unequalled; but to do this is not in the power of every one. To simplify, then, as much as possible the process of learning must be our object, and no system, however sound, can be really useful if it be complicated. For this reason alone more than one excellent teacher has failed.

Peach culture is not really difficult to practise; it may become so by injudicious treatment. When we read the

works of the best writers on this subject we cannot fail to see how simple the whole process seemed to be to the minds of some of them. In several the whole instruction for the summer and winter is contained in a dozen lines. To keep the roots well drained, to lay in a good supply of bearing wood, to remove that which had fruited, and not to shorten-in too much, were almost the only injunctions given. No indications were thought necessary by which the amateur could distinguish the various classes of shoots; some vague and general directions as to disbudding were added. It is evident that instructions of this brief and general nature presupposed a larger acquaintance with the subject than usually occurs with amateurs, and, being unaccompanied by illustrations, they, though written by first-class growers, failed to teach much. On the other hand, in such a plain matter as pruning the Peach, it is really absurd to attempt to teach it by elaborate and complicated rules. Much of the present style is of this kind (especially on the continent), and, on this account, will never be acceptable to English gardeners. The excessively-long pruning practised in the days of our fathers was, however, almost as pedantic and as strange to read of now. Here we find the traditional "good supply of young shoots, and thinning out the old and unproductive ones as soon as they appear naked," &c. Then comes the direction to lay in the "shoots of medium size, and full of flower-buds, at full length, from 2 to 3 inches apart." "All forerights and supernumeraries to be rubbed off during the summer months, as soon as they have reached an inch in length." In this case no cluster-spurs could be retained, and it is evident that, there being no mention of disbudding in this case, the long shoots, laid in closely, must have crowded the tree, and caused much overgrowth. What the tree must have looked like at the winter pruning it is impossible to say. Other later writers of eminence recommend the shoots to be shortened to 14 inches, if strong, and weak shoots to about 6. At Montreuil about 12 inches, in general, is the rule as to length of shoot.

The unnatural and needless system of disbudding seems to have many advocates in the authors before us. Indeed, with one author it constitutes the chief part of his recommendations. To lay in a shoot (the length not stated), but evidently at its fullest extent, and to disbud it in three times—(there is great stress laid upon this number)—to leave only the terminal bud, and one at the base—(for a replacing shoot)—and to allow one or more Peaches to grow on the naked shoot between them, is really the whole that is stated. Another writer considers disbudding a "most important consideration." It will, however, be seen that later practice prefers the judicious summer stopping of the shoot, whereby the same result is obtainable by more simple and natural means.

The result of such a style of long pruning almost always is, that far more wood is grown than is wanted. The tree exhausts itself, especially in our humid climate, in the production of long unripened shoots, and the pruner, at the winter season, sees before him three times as much wood as he requires for fruiting. If he be one

of the traditional school, opposed to every change, he proceeds to cut out, perhaps, two-thirds of the superfluous shoots, thereby rendering the tree liable to canker, and he has no choice left but to preserve the remainder, which, from the confusion and crowding of the past summer, are often unfit to bear. This may be an extreme case, but whenever a sunless summer occurs any similar system must fail. "The cautions," says McEwen, "given as to laying-in reserve shoots have done much injury; the vast amount of unnecessary wood laid in prevents the proper expansion of the leaves, or the action of the sun on the walls. Reserved shoots are only 'reserved' to be cut out, and green shoots, soft at the core, are the result, and a prey to a thousand diseases. This is smothering the tree with superfluous wood." And to the same purpose his Editor—"Over-cropping with wood is as injurious as over-cropping with fruit; both shorten the existence of trees." Much more might be added, but it is needless. In short it may be taken as certain that the system of long pruning tends to produce too much wood; that such wood is not fruitful, not having had its due share of our capricious sunshine; that the amputations of shoots and branches, rendered necessary for a "fresh supply," are dangerous in the extreme, and that the trees are extremely liable to become bare at the centre. If to this be added the injudicious forms of trees, and undrained borders, every failure seems easy of explanation.

It remains to suggest some remedy. All late experience tends in one direction—closer pruning. The results which have been obtained in the orchard-house, under very close pruning, serve to show that this system, when modified so as to suit the exigencies of the open air, contains within it the germ of a new style. Could this be made to suit, both for trees under glass and for those on the open wall, no doubt a great step would thereby be made towards uniformity and simplicity. Ten years of experiments made on trees in the open air have shown that this is possible.

"The Modern Peach Pruner" does not favour long pruning, but as, when properly practised, it may be rendered sufficiently successful, the ensuing chapter will contain what is considered the best method of so doing. The remaining chapters will be devoted to close pruning, and especially to describing an entirely new system of managing Peach trees on the open wall.—T. BRÉHAUT, *Richmond House, Guernsey.*

## KITCHEN GARDENING.

(Continued from page 432.)

HAVING thus far treated on light and dry soils, our next consideration will be those of a wet clayey nature, which are, generally speaking, the worst kinds of soil for a garden. The first thing to be done is to see that the ground is thoroughly drained, and then to trench it two spits deep all over; but instead of throwing the top soil in the bottom of the trench as is usually done, merely turn it back, and fork the bottom of the trench, replacing the top soil on the surface. As the trenching goes on have all manner of rubbish that can be procured wheeled into the trench. In fact, I always dispose of my rubbish-heap in that way, and the longer the manure is the better it will answer the purpose. It also frequently happens, that in consequence of a railway being made, or building going on adjacent to the garden, a good lot of cheap soil can be obtained and worked in to improve the natural soil. Road scrapings, lime rubbish, or anything that will lighten the soil should likewise be taken advantage of, not forgetting to manure well every time the ground is cropped. This system, if persevered in, will make the ground work well and produce earlier crops, which are great considerations as well to the amateur as to the market gardener.

Having thus far disposed of soils and the different systems of working them, I shall, as well as I am able, describe my system of cultivation and cropping, so as to maintain a good supply of vegetables and salads all the year round, hoping that my readers will not forget that it is of a small garden I am writing, and for men who take an interest in such.

Beginning with January, my supply of vegetables consists of Brussels Sprouts, Savoys, Coleworts, or Hardy Greens and Kale of sorts, with a good breadth of Winter Spinach. For salading I generally depend upon such as Mustard and

Cress, Endive, &c., under protection, the Celery being protected where it grows. The first lot of Rhubarb and Sea-kale is in by this time. The above is about all I can muster at that time of the year. As early as possible in the month I sow my first lot of Peas, Daniel O'Rourke, having previously selected and prepared a piece of ground on the border lying under the wall; and as a protection against mice below and birds above, I cut up a quantity of furze very small, and put in the drills with the seed, laying some more along the top in rather longer pieces. I do not find that the furze has any injurious effect on the future growth of the crop, and it acts as a very good preventive from all the ills that early-sown Peas are subject to.

While on the subject of Pea-sowing, perhaps I may be allowed to say a word or two about some new sorts that have rather put me out of my reckoning this year. My seedsman sent me a quart each of two sorts called Dickson's Early and Carter's First Crop. I sowed them exactly five weeks after Daniel O'Rourke, and under exactly the same circumstances. The two new sorts were fit to pick on the 26th of May, whilst Daniel O'Rourke was not ready till the 1st of June, and was not then in nearly such good condition when it was picked as the first-mentioned sorts, as the pods of these were as hard and full as any one could desire.

Before the month is out I sow two rows of Sangster's No. 1 in the open quarters, at 5 feet apart, thus leaving room for a trench in which to plant the thinnings of the Cauliflowers under hand-lights, which are succeeded in the trench by Celery. If the ground is at all in working condition, I plant some Potatoes in the open ground before the end of the month, well covering them with litter, though I have some planted at the same time in a three-light pit, putting the sets in deep, and sowing Radishes on the top. I very seldom sow any Lettuce in January as I have a good sort to stand the severity of the weather, called the White Cos, and if I can possibly get a piece of ground clear of winter stuff, I sow it with Early Longpod Beans. This month I generally cover up my second lot of Sea-kale and Rhubarb, for forcing under pots in the ground, as I can do better with it in that way than in any other, I also take the opportunity of wheeling any manure in the garden to any available place where there is room, among the growing crops of winter stuff, and on the borders. I prune the fruit trees and have the borders neatly dug, and as soon as a piece of ground is done with I trench it or ridge it at once, as it will not do to lose the pulverising effect of the frosty weather on the land. If any new plantations are in contemplation, it is a good plan to prepare for them before the busy season comes on, as January is about the slackest month of the year in the kitchen garden.—BUENTWOOD, P.D.

(To be continued.)

## LIQUID MANURE.

(Continued from page 427.)

HOUSE-SEWAGE AND URINALS.—The manure from these sources is more powerful than the drainings of dunghills, but is not suitable for pot plants, and such as require frequent applications of water. For fruit trees and garden crops generally it will be found more powerful, more stimulating, and more certain in its action than the drainings of a dunghill.

The tank for the reception of house-sewage should be at a distance from the house, and no place is better than a covered shed, where earth can be dried for the deodorisation of the more solid matter. There should be a place where this can be separated from the fluid, and at such a height that the latter may run off after a short time. This receptacle need not be either deep or large, but sufficient to hold the sewage and allow of the solid matter settling. It should be cleaned out once a-week, and the deposit mixed with dry soil. For this purpose soil is far preferable to ashes, and charcoal or peat is better than either. This solid manure is more stimulating than the dung of animals, but is not so lasting. It is not necessary to separate the solid from the liquid house-sewage, but if this is not done fermentation soon takes place, and the tank must be more frequently emptied, whilst it is hardly possible to use the contents without some disinfectant: besides, if the solid

matters are not separated from the fluid it is very difficult to judge of the strength. Cesspool sewage, when the solid matters are for the most part removed, should be diluted with fully six times its volume of water. On the other hand, when no part of the solid matter is removed, twelve times the bulk of water is not too much. In all cases the contents of the tank should be stirred to the very bottom. This liquid may be poured between the rows of growing crops, but not until the crop, whatever it be, is well rooted.

MIXED SEWAGE from household offices, stables, &c., is highly fertilising. It is usual for the water from the laundry and rain to enter the tanks. Sometimes the sewage is very strong, at others weak, and it is difficult to judge of its strength. Sometimes it may be used undiluted, being little better than so much soapy or greasy water; at others it requires to be much diluted, and this is the greatest drawback to its use, as there is ever a danger of applying it too strong.

I have now stated the three forms in which I have used liquid manure, and I have had three times as much experience with the first as the other two. I have not, in fact, used house-sewage or manure water containing it to other than the common kinds of plants, and for fruit and vegetable growing, and to these it has been applied with advantage. In using liquid manure give a thorough soaking, and at distant intervals. In the case of stone fruit trees a good drenching after the fruit is set enables them to swell famously, and another in ten days or a fortnight is all that is needed before the fruit stones, unless the weather prove dry, when its application may be continued every ten days or a fortnight, always bearing in mind that the oftener it is given the weaker it must be. Three good waterings—viz., one when the fruit is fairly set and swelling, the second in the first dry weather afterwards, and the third just when the fruit takes its second swelling, will be found ample in the majority of seasons for trees in the open garden. These waterings are for Peaches, Nectarines, Apricots, Plums, and Cherries.

With regard to Pears, it does not matter how much liquid you give them in dry soils, but on naturally strong soils they are not much benefitted by more than a soaking the first dry weather after the fruit is set, and again when it is about half swelled. Apples, like Pears, should have moisture in dry soils, but need less on retentive loams. Strawberries flourish with a thorough soaking just when going out of bloom, and twice a-week until the fruit is gathered. A moderately rich, deep, and firm soil, and plenty of nourishment when flowering and fruiting, seems to me all that is necessary to have plenty of Strawberries. Raspberries will swell and set their fruit finer than usual if deluged with sewage just when they are going out of bloom, and once a-week during the period of fruiting. Manure Raspberries, and they will give plenty of fruit and very strong canes for another year; but never dig the soil deeply round them, nor give much manure, except when they are fruiting. Gooseberries and Currants may have a dose when the buds first begin to swell, another when the fruit begins to swell after setting, a third when rather more than half-grown, and another when the fruit begins to colour. The leaves will be all the greener, and the fruit will not turn yellow and drop after setting, but will swell well.

In applying sewage to fruit trees, the ground at some distance from the stem should be watered, as well as that near the stem, and the same remarks apply to vegetable crops. It should be poured along the rows of Peas on both sides, and is one of the best means for obtaining plenty of tender Peas during hot weather. It may be poured between the rows of all the Cabbage tribe—Cauliflowers especially; it prevents them running to seed, and assists in rendering the head large, close, and firm. A thorough soaking once a-week during dry weather, or twice if very dry, will prove beneficial. Celery can hardly have too much, twice a-week will prevent woodiness. Kidney Beans, which succeed better than most vegetables in dry weather, continue much longer in bearing if supplied with liquid manure, and Potatoes, which are generally small in dry seasons, attain a larger size; but in this case it need not be given until the haulm is fully grown, for they usually make enough of this. Of course, if dry weather set in prior to the haulm attaining

its full size or flowering, then sewage may be given advantageously. One or two drenchings between the rows during dry weather will mostly be enough for Potatoes. Asparagus, which it is always desirable to have large and fine, may be watered twice a-week during dry weather, from April to August. In short, there is not a crop which is not benefited by the application of sewage in large but not strong doses. The necessity is greater for its use during dry weather; but in showery periods sewage enriches the soil, and the crop shows the good effects. I imagine, that after the application of sewage the ground remains longer moist than after an equal watering with water, and crops appear to do better when the sewage is given a few days before rain. It is hardly possible to apply it at a wrong time where bulk is wanted, but it should not be given when crops are not growing, or to those that are already too luxuriant. During wet weather it may be poured in an undiluted state on ground before cropping, and it then answers the same purpose as manure. Any smell is soon gone. After applying manure water great benefit is derived from hoeing or stirring the surface so as to admit air into the soil.

In addition to using manure to the crops already enumerated, I have applied it to Roses, Dahlias, Asters, Calceolarias, Hollyhocks, and many other plants from the time of their commencing to grow to that of their going out of bloom; once a-week in damp periods, and twice a-week during very dry weather. Some plants and trees do not appear to be benefited by liquid manure. This is more or less the case with the Pine and Fir tribe, though they grow better on manured than unmanured ground. Heaths will not bear it, and all bog plants seem to be improved neither in foliage nor flower, even by weak applications. These plants appear to require vegetable and not animal manures. Hollies care nothing for manure water, Laurels are improved by it, but Yews do not make one twig more though they grow the better of manure. Ferns, whilst they luxuriate in decaying vegetable matter, are not improved by solutions of solid manures, and perish under powerful doses.—G. ABBEY.

#### THE DUC DE MALAKOFF STRAWBERRY.

I PLANTED last August some runners (fine plants) of the Duc de Malakoff Strawberry; these are, at present, very healthy, but show no sign of producing flowers. Will you inform me whether it is usual for this variety of Strawberry not to produce fruit the first season after it is planted, and if not, what means should be taken to induce fruit-bearing?—R. T. C.

[The Duc de Malakoff is a fine juicy and vinous berry in the line of Ajax and Ambrosia, but better than either. I had them all three side-by-side some years ago, and did not find any of them crop satisfactorily on the whole. Some plants of the Duc de Malakoff cropped well, but four plants out of six had nothing, after having had a previous summer to gain strength, being deprived of flowers and runners, so I discharged it. I cannot, therefore, say what it would have done in the future. I believe that this severe spring the flowers of many Strawberries were cut off, or, being set, were stopped by the frosts. No doubt many of mine will not come to maturity from the above reason. Mr. Turner in his letter of this morning (June 10th) says—"Strawberries generally are but badly bloomed." Here, on the whole, I shall have good crops, deducting even many failing berries. I have excellent crops of the following:—Sir J. Paxton, ripe on Whit-Sunday, large, handsome, and good, a valuable early sort; Rivers' Eliza, which I am now picking; Wonderful; John Powell, very delicious; Scarlet Pine, very delicious; Eclipse, very good; Royal Hautbois, the best Hautbois; Eugénie, a large and useful sort; and Frogmore Pine, a most noble sort. I have eaten ripe berries of all these, except the last, to-day (June 10th), and have sent a mixed basket of Sir J. Paxton and Eliza to-day to my kind friend Mr. Sturt of Critchill. Still, though with unweary watering, I shall have fine and superabundant crops, I can fancy that some berries that are "set" will come to "nil." I have added 800 yards of netting to my previous stock to keep off birds, which, if this dry weather last, will soon make a raid on our gardens. I would advise your readers to keep runners off their Strawberry plants and

water copiously, otherwise their crop and season will be short. After the berries are set in dry lands, till they redden, too much water in hot weather cannot be poured on them. After every picking this must be repeated. My servant says that he thinks the crops here are better than last year, and that El'za is again the best cropper. I have had it for many years, and it has never failed me.

I cannot conclude without saying how grieved I am to read of the death of Sir Joseph Paxton—so valuable to the horticultural and floricultural world, and to whom this nation is so greatly indebted. His talent, his integrity of purpose, and his good common sense, will be missed and wanted! I am sure that I express a universal feeling.—  
W. F. RADCLYFFE, *Tarrant Rushton.*]

### STRAWBERRY CROP.

THE failure of Strawberries in these parts (West Middlesex), is beyond all precedent. Fine stools did not produce a single truss. Others had a few trusses, the early blossoms of which were killed by frost. Many of the secondary buds have suffered in a way I cannot account for. The calyx is killed and turns brown before the flower expands, while the embryo fruit is quite fresh, but of course will never expand any farther, much less come to maturity. The chief mischief must have been caused last year, for my beds were never so well done, and were all dug and mulched last Michaelmas. My son tells me that tons have been sent in from the West of England; so I suppose they are better off there.

Pears have suffered immensely from the maggots of that fly, which you may remember I figured—from five to twenty-five maggots in a Pear, and Beurré de Capiaumont, which would have borne six bushels, will not have six Pears! This pest bids fair to rival the Vine mildew in its destructive character, and we seem still more powerless in preventing its ravages.—F. J. G.

### VISITS TO GARDENS PUBLIC AND PRIVATE.

#### THE PALACE GARDENS, LONDONDERRY.

As the readers of THE JOURNAL OF HORTICULTURE are probably by this time aware, the gardens that I have the opportunity of visiting are of a very varied character; but I have invariably found that a good deal of the character depends on the gardener under whose care they are placed. The days are past, I think, for the class of gardeners who knew their work and were above it, and those who did not know their work and made believe that they did; and I believe employers generally have a better idea of the intelligence, skill, and constant forethought required in those who are employed in that capacity, and treat them accordingly; while gardeners do not now, as at one time was not uncommon, pursue their own way without in the least caring what his lordship, or one who is oftener a far more important personage, his *chef de cuisine*, thought about it. And this is only as it should be. It is very easy on gala days to admire the wonderful bunches of Grapes and the delicious Pine that grace the dessert; but surely something ought to be thought then, not only of the wealth that has provided the means whereby opportunity for growing such was afforded, but also of the skill of those whose watchfulness and intelligence have had so much to do with it; while, on the other hand, if a gardener finds that Sir Jasper or Lord Broadacres has his peculiar fancies, and wishes to have things done in a particular way, it is equally clear, I think, that those wishes should be attended to: no dignity is lost, and a great deal of comfort is gained by so doing. I have known places where a gardener, persisting in carrying out his own plans, has so thoroughly disgusted his employer, that he gradually lost all interest in his garden; while, when the garden changed hands, and one undertook it who properly considered what was due to his employer, an interest greater than he had ever had before was aroused. Old houses were taken down and new ones built, and the garden became a daily source of pleasure. How many employers have I known who hardly knew one flower from another, who have been so inoculated by the zeal and energy of their

gardeners, that they have become zealous amateurs, and have even budded into exhibitors.

I have been led into this train of thought by a visit lately paid to the Palace Gardens at the Bishop of Derry's—by no means what would be called show gardens, and what, in fact, by many of our southern friends would be considered very indifferent. But without that they have a good deal of interest, for there has been a battling with all sorts of adversaries. When the present excellent prelate came to the see, the cathedral and the garden were much on a par. In the former, the hideous deformities of what some one has called the dark ages—the last century—had destroyed any architectural beauty, though it never could destroy the historic interest of those old walls, to which in former days the citizens of Derry crowded to hear George Walker exhort them to steadfastness in the cause of liberty and truth; while in the latter there was, in fact, nothing but a wilderness. It had been let out for the sake of the fruit trees; grass had grown over the whole of the five acres which it contains, and there was not even a path in it. To restore the cathedral was the good bishop's first care, and it had been opened again just three years on the very day that I visited it. The garden was an after-consideration; but it was not until the present intelligent and earnest gardener took possession of it that real progress was made; and not only were there difficulties of this nature, but the soil is not naturally a good one. It rests on shale, I believe, and is consequently somewhat hungry, while in that northern climate I was assured by the gardener that the most sunny and summery weather was in the months of April and May, and yet nowhere have I seen a better promise both of flowers and fruit. The old wall trees have been replaced by new and excellent varieties of Pears, for to ripen Peaches out of doors so far north is out of the question, and the attempt has been consequently abandoned. Peas were well in bloom, but they had been grown in turves in-doors and then planted out. Experiments were being made on some of the early kinds which have been so much vaunted this season, and about which I fear we shall find that there has been a good deal of *hum*. One sort I tried last year which was to be ever so much earlier than Daniel O'Rourke, whereas it was really eight or nine days later. I learned here what may be an old, old story to many, but which to me was new—that the best method to prevent the birds from eating seeds is to soak these before sowing in a solution of red lead, about a teaspoonful to an ounce of seed; the lead to be mixed with a small quantity of water in a basin, and then the seed thrown in and well shaken about in it. I was assured by Mr. Goodman that this answered completely, that he had tried various ways, but that no plan was so effectual as this. To those who live in the neighbourhood of towns especially, into whose gardens all the sparrows of the locality come to picnic, this may be worth knowing. I saw the beds so treated: evidently the vitality of the seed had not been destroyed, for nearly every seed must have grown, while beds not treated thus and netted had been ravaged by the rascals, who, although they may do some service, do also a good deal of injury.

The amount of glass was small, but it was well managed. I have never seen Vines in pots better grown, and those planted in the house were also evidently thriving. Muscat of Alexandria was preferred to any of the same class; and Chavoush, Royal Vineyard, and other new sorts were being introduced. Strawberries (Black Prince and others), were and had been for some time fruiting; and abundance of rich and luscious fruit bore testimony to the excellent manner in which they had been treated. In the centre of the garden is a long walk extending from end to end, with fine Privet hedges at each side. This was to be planted as a ribbon-border, the background being formed by Holly-hocks; and Lobelia, *Perilla nankinensis*, scarlet Geraniums, and variegated Mint were used to complete the ribbon. I have no doubt that when in flower this will have a very fine effect. In the various squares vegetables of all kinds were doing well, although the presence of some old but good varieties of Apple trees hindered that completeness which all good gardeners, Mr. Goodman amongst them, desire. One or two I noticed were laid down in grass, and I found on inquiry that this was done in order to give the land a rest. It had been so abused for many years, that this

seemed the only practicable plan. It would be afterwards dug in, and, it was hoped, a new character be given to the land. Thus things were not done in a careless style, but intelligence and energy were brought to bear; and where this is the case difficulties, even those of climate, are successfully combated. In noticing these gardens I have had in my mind many somewhat similarly situated, where employers and gardeners are discouraged by the difficulties that lie in their way, and are apt to envy their more favoured brethren in other localities; but let them take heart of grace.

I should not omit to say that a good deal of stimulus has been given to gardening in the neighbourhood of Derry by the establishment of a horticultural society, very similar in its rules and working to that which we have had in our neighbourhood, and which has been a very great encouragement to all kinds of gardening amongst us. I am sure that it is a great boon to any place, where such things are attempted and done; and however discouraging the attempt may at first sight appear, the difficulties will be eventually overcome.—D., *Deal*.

### ROYAL HORTICULTURAL SOCIETY.

FLORAL COMMITTEE, JUNE 10TH.—A Sub-committee was held in connection with the show of the same day. Seedlings and florists' flowers were few in number, and of no particular merit. The new plants were very numerous and interesting, and upwards of sixty certificates were awarded, nearly all the plants having previously received awards from the Committee. It seems a strange custom for the new plants to receive certificates again at the great shows; it appears more reasonable that plants of the current year which have been awarded certificates should on these occasions have the certificates attached to them, and should then be exhibited in collections, and the greatest number of first-class certificates in the collections should entitle the exhibitor to the gold Banksian medal, and the second most valuable collection should have the second gold Banksian medal.

On this occasion Messrs. Veitch and Mr. Bull carried off the greatest number of certificates. Mr. E. P. Francis exhibited a seedling Zonale Pelargonium, Hertford Gem. Mr. Bull sent again Verbena Popular, a variegated form; Chrysanthemum Sensation, a beautiful variegated Pomponé, useful for edging, and which received a first-class certificate; six seedling Petunias, of which one named Blooming, a dark-veined variety, was the best; Mimulus duplex seedlings; Fuchsias Evangeline and Hector; a beautiful collection of Zonale Pelargoniums in small pots; also a large collection of spotted Pelargoniums. From Messrs. Veitch came Good-yea Veitchii, a hybrid with beautiful foliage, to which was awarded a first-class certificate on the 16th of May, and the same at this meeting; and from Mr. Wilson Zonale Pelargonium Fulham Rival, also variegated Zonale Pelargonium Lady Howard. Messrs. Henderson, Wellington Road, sent two of the new double scarlet Pelargoniums, with weak and ragged trusses; unless these double varieties improve very much they will not be favourites with the public; also Pelargonium peltatum elegans, which is quite an acquisition among the old-fashioned Ivy-leaved Pelargoniums—bright green foliage, flowering freely, with pale lilac or rosy compact trusses, decidedly a very distinct and very good thing. It received a first-class certificate. It is somewhat remarkable that this useful section of Pelargoniums is not taken up for improvement, though so very well adapted for basket and all decorative work. Messrs. E. G. Henderson also exhibited Petunia variegata, Joseph Haudrechy, plants too small to afford any opinion of their merit; and Centaurea ragusina compacta, very like C. argentea, but more compact and feathery in foliage. It received a first-class certificate. Mr. J. Fraser exhibited six seedling Pelargoniums, but none of them sufficiently distinct or improvements on others in cultivation. Mr. Thompson, Ipswich, sent a Primula Parryi, with deep purplish rose flowers, in foliage very unlike its relatives—first-class certificate; Pentstemon grandiflorum, from North America. This is a noble plant of robust habit, bearing large, pale lilac flowers which are too much closed, but it

will, doubtless, be the source of quite a new feature among Pentstemons, which have been so much improved of late. A first-class certificate was awarded it.

MR. BATEMAN'S LECTURE ON DENDROBIA, JUNE 13: Mr. Henry Cole in the chair.—Mr. Bateman, in commencing his lecture, briefly adverted to Coryanthes Summeriana, Cypripedium caudatum, and Aërides crispum, which were, along with some other Orchids, in the room. The subject of his lecture, however, said Mr. Bateman, was the great Indian genus Dendrobium. Rumphius had made a division of Orchids which was not so cumbersome as that adopted by modern botanists, and was probably better adapted for those who had little or no knowledge of the subject. Rumphius divided Orchids into two classes—the noble one, or those which grow on trees, and the rustic one, or those which grow on the ground. Thus, with Orchids, there was high life and low life, but no middle class—they were all either patricians or plebeians. To the former belonged the Dendrobia, and to the latter the Orchids which we had plucked in early years by the hedge-sides. Whether it were true or not that the cradle of the progenitors of our race was in Armenia, between the head-waters of the Euphrates and Tigris, he would not pretend to say, but certain he was, that Milton was right in placing no Orchids on the trees in the Garden of Eden. It was not until the fifteenth or sixteenth century that man took any intelligent notice of tree Orchids; and the discoverers of America were so bent on the pursuit of mammon that they passed the Orchids on the trees without noticing them. Old Hernandez, a Spanish botanist, was the first to give anything like a figure of a tree Orchid. That was early in the seventeenth century. In the frontispiece to his work, from which he had borrowed the large sketch hung up in the room, were three Orchids, one of which, there could be no doubt, was Stanhopea tigrina, and another was Lælia grandiflora, although Hernandez had dragged them down from the trees to the ground. They were described under barbarous names—the Lælia, for instance, as Cortico-atzonte-coxotchil, which should make us thankful for such names as we now have. Turning now from the new world to the old, more than a century afterwards Rumphius propounded a theory which, if not his own, he endorsed. Noticing the resemblances which certain Orchids bore to birds, beasts, and insects, his theory was that these plants had their origin in the droppings of the animals which the plants resembled. Absurd as this theory was, it was not, perhaps, more so than some of our own day. Reverting to Rumphius's division of ground and tree Orchids, Rumphius had named the latter all Angraecum, a name which, it was believed, was derived from the Malayan word for tree; and, though the name still held its ground as applied to that popular and increasing genus, the Angraecums, these were entirely confined to Africa, and a name was still wanted for the tree Orchids of the east and of the west. Linnæus called the latter Epidendrum, from *epi*, upon, and *dendron*, a tree, because they all grew on trees; and he thought that, when the world was fully explored, there might be a hundred species of tree Orchids, little dreaming that there would be not merely a hundred species, but at least as many genera, some with between 200 and 300 species. Swartz, another Swedish botanist, called one of these Dendrobium, from *dendron*, a tree, and *bios*, life, they living on trees like the Epidendra of the western hemisphere. Sir Rowland Hill had put us all in districts, and, if he (Mr. Bateman) might be allowed to imitate Sir Rowland, he would do the same with Orchids. Referring to a map of the world hung up in the room, Angraecum, being peculiar to Africa, might be taken as representing S., or the southern district; Dendrobia, E.C.; Epidendrum, W.C.; and the ground Orchids of more temperate regions would supply the other letters. He had long been doubtful whether Epidendrum or Dendrobium would head the poll. Twenty-five years ago, when he began to cultivate Orchids, the former had the lead, but now he thought Dendrobia were the more numerous. Each genus numbered between two and three hundred; but numbers were not the best test, but beauty. Out of forty or fifty Epidendra which he had grown, he found only three worthy of being kept, and two of these were in the room—namely, E. vitellinum and E. macrochilum roseum. On the other hand, out of the same num-

ber of *Dendrobium*, after "scratching" all that were not worth growing, more than three-fourths remained. He would now endeavour to give some notion of their growth. The most simple form of *Dendrobium* was one bulb, one leaf, and one spike of flowers, proceeding sideways from the top of the bulb, as in *D. aggregatum*. The next form was a longer bulb, and two leaves, as in the Australian *D. speciosum*; then we come to four or five leaves, as in *D. densiflorum*, but the racemes were still produced in the same way. Further progressing, the bulbs almost disappear, and stems make their appearance, clothed with leaves all the way up, as in *D. Wardianum*. *Epidendrum* are readily distinguishable from *Dendrobium* by the spike coming out at the top of the bulb, and forming a continuation of the latter, whilst in *Dendrobium* the spike is produced at the side. Those first imported were far from the most attractive, and the most beautiful were those which reached us last. Some of these were exceedingly local. Thus, in Ceylon, where much novelty is not likely to occur, not long ago was found the beautiful *D. MacCarthiae*, figured in the "Botanical Magazine" from dried specimens sent home by Mr. Thwaites; and Mr. Bateman urged clergymen and young officers abroad to look for such plants, and send them home. He next directed attention to *D. Falconeri* and *D. Falconeri obtusum*, both of which he had long suspected to be perfectly distinct, and he found that to be the case. The latter was figured in Mr. Warner's work as *D. Wardianum*, which is to be its name henceforth. He had endeavoured to have them both in flower at the time of his lecture; but in the one case half the flowers had dropped, whilst in the other they were not yet in their beauty. Among the merits of *D. Wardianum* was the great endurance of its flowers. Another beautiful species, *D. taurinum*, from the Philippines, was also referred to. No *Camellias*, Mr. Bateman said, and scarcely any *Roses*, would carry through a long London night, but these *Orchids* would run half a dozen nights; and he urged the ladies to try how long the bloom would last, as any experience in that way would be a guide to nurserymen, and that class now springing up who grow these flowers for the London market. Other *Dendrobium*s belonged to a class which he had called bridal *Orchids*, because they presented the colours which, by a sort of tradition, were associated with brides, though he did not suppose *Orange* flowers would be superseded. One of the most beautiful was *D. formosum*, yellow and white, which would last a month. A few gems had yet to be looked for. In the large island, he might almost say continent, of New Guinea a vast number of *Orchids* were known to exist, but scarcely any of them had as yet been introduced. Turning now to Borneo, he held up a dried specimen of a *Dendrobium*, called by the natives *Kina-balon*, with beautiful flowers; also a leaf, measuring some 15 inches long by 12 wide, sent home by Mr. Thomas Lobb, but unaccompanied by any flower. If, remarked Mr. Bateman, we did not know it came from Borneo, we might suppose it came from Brobdignag, and he gave it the name of *Dendrobium gigas*. As regards culture, *Dendrobium* could not be classed among cool *Orchids*, or those which would succeed treated in that way all the year. During three or four months, while making their growth, they required a good, strong, moist heat; but this was only in summer, and for the rest of the year they might be kept in a cooler temperature. Thus, the plant of *Dendrobium Falconeri*, which he had brought to illustrate his lecture, had spent the last month in a cool vinery. For those who could cultivate but a single genus, none would repay them better than *Dendrobium*. Some might prefer *Cypripedium*, some *Oncidium*, and others a selection of different genera; but whatever form the *Orchid* mania might take, it would afford change and relaxation to the overwrought brain. *Orchids* were capable of producing this result; even *Fungi* had many lovers. He would relate an anecdote of Dr. Klotzsch, who in Germany reigned supreme over *Fungi*, or *Foongi*, as he (Dr. K.) called them. They were his speciality, though he was a good general botanist as well. Travelling in Scotland, many years ago, with Dr. Davidson, and having called at the post-office for their letters, Dr. Klotzsch received one from home that plunged him in the greatest grief. So profound was it that it was some time before Dr. Davidson ventured to ask him the cause. When at length he did so, Dr. Klotzsch informed him that the letter had brought him

the news that he had lost £300. Dr. Davidson was somewhat disappointed at the way in which the German professor took the news, and at length he felt it his duty to gently remonstrate. He did so, when Dr. Klotzsch faltered out—"It is not the £300 that I care about, but I had set it apart to investigate the *Fungi* of Hindostan; no one besides myself will go to see the *Fungi* of Hindostan, and that I shall never be able to do." But there is "no cloud" without "a silver lining," added Mr. Bateman, and at length Dr. Klotzsch exclaimed—"I thank God for that He hath put the love of *Foongi* in my heart, and when I see a *foongus* I am happy." What *Fungi* did for poor Dr. Klotzsch, other plants might do for us; and Mr. Bateman instanced Solomon as one who, amid all the distractions of a court and kingdom, knew every plant, from the Cedar on Lebanon to the Hyssop on the wall; and concluded his lecture with an eloquent peroration, which met with much applause.

Mr. G. F. Wilson moved a vote of thanks to Mr. Bateman, also to Dr. Lindley and Mr. Veitch for the specimens and plants lent by them; and Mr. Bateman, in returning thanks, called attention to some *Orchids* just imported by Mr. Veitch from the north coast of Australia, one of which is known to bear most beautiful rose-coloured flowers, and the other was *D. Hillii*, of which a representation is given in the "Botanical Magazine," producing a spike of white fragrant flowers resembling an officer's plume.

**AZALEA SHOW, JUNE 17.**—Of this it was stated in a notice posted up at the entrances, that "the unusual forwardness of the season has made it impossible to have a full show of *Azaleas*," and there were only such as occurred in a very pretty collection of stove and greenhouse plants and *Orchids*, from Messrs. Lee, of Hammersmith, who also contributed half a dozen boxes of beautiful cut *Roses*. A similar exhibition came from Mr. G. Clarke, Brixton Road; and Mr. Bull furnished a numerous collection of new plants, *Ferns*, *Dracænas*, &c., and a fine pan of *Trichomanes speciosum*.

## ROYAL BOTANIC SOCIETY'S SHOW.

JUNE 14.

THE second great Show again afforded a magnificent display, and though the number of plants exhibited was probably scarcely so large as on the previous occasion, there were numerous and gorgeous stands of *Roses* and the additional attraction of fruit. The weather was highly favourable to an out-door exhibition, being very warm, and, notwithstanding the counter-attraction of Ascot, the lawn was crowded with several thousands of visitors, the fair sex largely predominating.

**STOVE AND GREENHOUSE PLANTS.**—Numerous collections were shown, some of which were very good, but the plants of which they were composed presented little difference from those noticed last month. *Allamandas*, consisting of *A. cathartica*, *Schotti*, and *grandiflora*, were in good bloom, especially the last-named from Mr. Peed and Mr. Page, and the first two from Mr. Whitbread, who also had a fine *Vinca rosea*, and *Gompholobium splendens* well set with its yellow blooms. *Ixora salicifolia* with fine heads of bloom was noticeable in Mr. Peed's collection, as also a fine *Erica obbata*. *Clerodendron Thomsonæ* was again in fine bloom as shown by Mr. Kemp and Mr. A. Ingram, and *Rhynchospermum jasminoides* was well represented in several collections; so too was *Dracophyllum gracile*. Mr. Fraser again exhibited his grand plant of *Phænocoma prolifera*, in company with others shown at Kensington in the previous week; and from Mr. Donald came *Sollya linearis* with a profusion of its deep blue flowers. Of *Pimelea decussata*, a nice little bush was shown by Mr. Rhodes, also a very good *Dracophyllum* and *Pleroma elegans*; and in Mr. Chilman's collection we noticed *Aphelaxis macrantha rosea* in fine bloom; and the purple variety in a very good collection from Mr. C. Smith, also *Azalea coronata* in fine bloom. *Hæmanthus puniceus*, a very old but showy Cape bulb, was shown by Mr. Baxendine with four of its brilliant orange scarlet heads.

**Prizes**—For sixteen: first, Mr. Whitbread, gardener to H. Collyer, Esq.; second, Mr. Peed, gardener to Mrs. Tredwell;

third, Mr. Kaile, gardener to Earl Lovelace. For ten (Nurserymen): first, Mr. Fraser; second, Mr. Rhodes; third, Mr. Baxendine. For ten (Amateurs): first, Mr. Chilman, gardener to Mrs. Smith, Epsom; second, Mr. A. Ingram, gardener to J. J. Blandy, Esq., Reading; third, Mr. Page, gardener to W. Leaf, Esq.; fourth, Mr. Wheeler, gardener to Sir F. Goldsmidt, Bart. For six: first, Mr. C. Smith, gardener to A. Anderson, Esq.; second, Mr. Donald, gardener to J. G. Barclay, Esq., Leyton; third, Mr. Wheeler, gardener to J. Phillpot, Esq.; fourth, Mr. Kemp, Albury Park.

**FINE-FOLIAGED PLANTS AND FERNS.**—A remarkably fine collection of the former came from Messrs. A. Henderson and Co., in which *Alocasia macrorrhiza* variegata was very fine, the large leaves being in some cases half white. *A. metallica* was also fine, as well as two large *Caladiums*, *Belleyme* and *Chantini*, the white-marked leaves of the former contrasting well with the red of the latter. The others were a large *Pandanus*, variegated *Crotons*, and *Maranta Porteana*, with the leaves barred with white, and red on the under side. A good collection was also shown by Mr. Young, consisting of *Palms*, variegated *Yuccas*, and *Maranta fasciata*. Of exotic Ferns fine collections were shown by Mr. Hill, gardener to R. Hanbury, Esq., and Messrs. A. Henderson & Co., comprising large plants of *Cibotium Schiedei*, barometz, and princeps; *Alsophilas*; the pretty *Gleichenia dicarpa*; *Drynaria morbillosa*, conspicuously veined with red; *Pteris crenata*, with long narrow leaves; and in other collections were the white variegated *Pteris argyræa*, *Adiantums*, *Platynerium*, &c. Interesting collections of British Ferns came from Messrs. Ivery, and Mr. Holland, Isleworth.

**Prizes**—For fine-foliaged plants: first, Messrs. A. Henderson & Co.; second, Mr. Young. For twelve exotic Ferns: first, Mr. Hill; second, Mr. Young; third, Mr. Sutton, gardener to Lieut.-Colonel Jeakes. For twelve British: first, Messrs. Ivery; second, Mr. Holland.

**ORCHIDS** made a beautiful display, notwithstanding the introduction of some inferior specimens to make up the requisite number in the larger collections; and, as an eminent orchidist remarked, it would be much better to restrict the numbers of plants required from private growers, very few of whom can bring so many as twenty in first-rate condition. Mr. Bullen, as usual, exhibited a fine group of twenty, in which were the *Moulmein Dendrobium Parishii*, in fine bloom; *D. chrysotoxum*, just expanded, and not so fine as it soon will be; *Cœlogyne asperata*, with cream, orange, and cinnamon-coloured flowers; *Brassia Henchmanni*, pale green, black, and yellow; a large *Aërides odoratum*, an excellent *Cypripedium barbatum superbum*, *Oncidium ampliatum majus*, *Trichopilia crispa*, under the name of *T. gloxiniflora*, and *Uropedium Lindenii*, one of the American tailed Orchids, and a very good specimen. Mr. Baker sent the curious *Dendrochilum filiforme*, with pendulous strings of yellowish green flowers; good *Aërides*, *Saccolabiums*, *Vandas*, *Lælias*, *Cattleyas*, and *Cypripedium superbiens*, wrongly named *grandiflorum*, with nine large blooms, and *C. Hookeriæ*. *Phalænopsis*, *Anguloa Clowesii*, *Cypripediums*, among which was a fine example of the new and beautiful *Stenei*, and *Orchis foliosa*, but not so fine as we saw it a year or two ago, were furnished by Mr. Page. *Odontoglossum hastatum*, under the name of *Oncidium alboviolaceum*, *O. sessile*, in excellent bloom, together with various *Cypripediums*, a *Vanda*, &c., came from Mr. Peed. Mr. Veitch sent *Anguloa Clowesii*, with no less than fifteen or sixteen of its fine yellow Tulip-like blooms; *Vanda suavis*, with three fine spikes; *Aërides Lobbii*, and *Cypripedium barbatum superbum*. In a collection of twelve, from Mr. Wilson, gardener to W. Marshall, Esq., were *Cattleya Acklandiæ*, with five fine blooms; *C. superba*, most brilliant in colour, magenta and deep crimson; *Cypripedium Hookeriæ*; and *Dendrobium infundibulum*, with seven of its beautiful white and orange flowers. In other collections we noticed various *Phalænopsis*, *Vandas*, *Cypripediums*, *Saccolabiums*, *Cattleya citrina* and *Mossii*, *Odontoglossum Phalænopsis* and *nævium majus*, and *Dendrobium moschatum*, a free-blooming species, easy of cultivation, and bearing considerable resemblance to *D. Dalhousianum*.

**Prizes**—For twenty: first, Mr. Bullen, gardener to A. Turner, Esq., Leicester; second, Mr. Baker, gardener to

A. Basset, Esq.; third, Mr. Page; fourth, Mr. Peed. For twelve: first, Mr. Penny, gardener to H. Gibbs, Esq., Regent's Park; second, Mr. Wilson; third, Mr. A. Ingram. For six (Amateurs): first, Mr. Wiggins, gardener to W. Beck, Esq.; second, Mr. Chilman; third, Mr. Robson, gardener to G. Cooper, Esq.; fourth, Mr. Wheeler, gardener to J. Phillpot, Esq. For six (Nurserymen): first, Mr. Veitch; second, Mr. Williams; third, Messrs. Lee; fourth, Messrs. Jackson.

**ROSES**.—In consequence of the hot season those in pots were not so fine as at the earlier exhibitions. We noticed, however, a fine collection, in small pots, from Messrs. Paul and Son; and among the large plants of Mr. Turner and Messrs. Lane good examples of *Souvenir d'un Ami*, *Victor Verdier*, *Madame Damaizin*, and *Paul Perras*. Mr. Turner had beautiful stands of cut blooms, among which *Cloth of Gold*, *Madame C. Crapelet*, *Alpaide de Rotalier*, *Gloire de Santenay*, *Devoniensis*, and *Madame Bravy* were very fine. In the Amateurs' class it is rare to meet with such blooms as those which came from Mr. May. *Boule d'Or* was remarkably fine, and so, too, was *Triomphe de Rennes*. *Comtesse de Chabillant* was very large for that kind; and there were fine examples of *John Hopper*, *Madame Bravy*, *Charles Lefebvre*, and *Souvenir d'un Ami*.

**Prizes**—For ten, in 13-inch pots: first, Mr. Turner; second, Messrs. Lane. For six: third, Mr. Terry; fourth, Mr. Young. Cut blooms, twenty-five varieties (Nurserymen): first, Mr. Turner; second, Messrs. Paul & Son; third, Mr. W. Paul and Mr. Mitchell. Twenty-five (Amateurs): first, Mr. May, gardener to C. M. Worthington, Esq., Caversham Priory, Reading; second, Mr. Ingle, gardener to G. Round, Esq.; third, Mr. Exall, gardener to J. Hollingworth, Esq., Maidstone. Extra, Miss Crawshaw; Mr. Wright, gardener to Mrs. Ramsden, Twickenham; Mr. Evans, gardener to C. Newdegate, Esq. Single blooms: first, Mr. Turner; second, Messrs. Paul & Son and Mr. Exall.

**AZALEAS**, generally, were far past their best. Among those from Mr. Veitch, *Violaæa superba*, *Iveryana*, *Extrani*, and *Juliana* were in very good bloom.

**Prizes**—First, Mr. Veitch; second, Mr. Fraser. Amateurs: first, Mr. Wheeler, gardener to J. Phillpot, Esq.; second, Mr. Peed; third, Mr. Kaile.

**HEATHS**.—Many excellent plants were shown in the collections of Mr. Rhodes, Mr. Peed, and others. *Ventricosa magnifica* was very showy; so, too, was the crimson *Westphalingia*, and the scarlet and green *Massoni*. Among whites were *Eassoniana*, *Vernonii*, *Jasminiflora alba*, and *Shannoni*; and of the tricolor class, *tricolor Wilsoni*, *t. rosea*, and *t. flammea*.

**Prizes**—For ten: first, Mr. Rhodes; second, Messrs. Jackson; third, Mr. Baxendine. For eight: first, Mr. Peed; second, Mr. A. Ingram; third, Mr. Page; fourth, Mr. Kaile. For six: first, Mr. Chilman; second, Mr. C. Smith; third, Mr. J. Wheeler; fourth, Mr. G. Wheeler.

**PELARGONIUMS**.—Conspicuous among these was a fine collection from Mr. Bailey, gardener to T. T. Drake, Esq., Shardloes. Among them *Sanspareil* was a splendid mass of bloom; and *Spotted Gem*, *Lord Clyde*, *Guillaume Severyns*, *Glowworm*, and *Lady Canning* were also very good. Mr. Turner also had a fine collection, in which were *Fairest of the Fair*, *Desdemona*, *Lord Clyde*, *Ariel*, *Glowworm*, and *Viola*. *Couleur de Rose*, in Mr. Fraser's twelve, was conspicuous for its brilliant colour. In *Fancies* Mr. Bailey had a large silver-gilt medal awarded him for excellence of cultivation. His plants, it is hardly necessary to observe, were very fine. They consisted of *Arabella Goddard*, *Roi des Fantaisies*, *Clemanthe*, *Madame Rougère*, *Delicatium*, and *Princess Royal*. Mr. Turner also exhibited a fine collection containing several of the above sorts.

**Prizes**—For twelve (Nurserymen): first, Mr. Turner; second, Mr. Fraser; third, Messrs. Dobson & Son. For ten: first, Mr. Bailey; second, Mr. Wiggins. For six *Fancies* (Nurserymen): first, Mr. Turner; second, Mr. Fraser. For six (Amateurs): extra first, Mr. Bailey; second, Mr. Donald.

**NEW PLANTS AND MISCELLANEOUS**.—There was again a long array of new plants, but most of them have been already noticed in our columns. Mr. Veitch had the beautiful *Bertolonia guttata*, Mr. Dominy's new hybrids between *Anætochilus* and *Goodyera*, *Urceolina aurea*, with large, pen-

dulous, yellow flowers, a fine-foliaged *Philodendron*, *Marantas*, and *Gymnogramma flexuosa*; Mr. Williams, the beautiful *Phœnicophorium sechellarum*, *Phalœnopsis Lüdemanniana*, *Smilax macrophylla maculosa*, with silver-variegated leaves, a pretty *Gleichenia*, *Anæctochilus Turneri*, with beautiful rose veinings on a dark ground, and *Colocasia longiloba*, with pale green leaves. Messrs. Ivery exhibited some new hardy Ferns, among which were *Polystichum angulare decurrens*, and *P. a. rotundatum*; and Mr. Bull, new *Aucubas* and *Rhodeas*, *Smilax macrophylla maculosa*, *Pandanus latissimus*, with rather broad pale green leaves, and many others seen at Kensington on the previous Saturday. *Richardia hastata*, *Centaurea ragusina compacta*, and the variegated *Cheiranthus Marshalli*, came from Messrs. E. G. Henderson. Seedling *Pelargoniums* were rather numerous, the best were *Charmer* and *Sparkler*, from Mr. Bull; *Nero*, clouded scarlet, with a white eye and dark top, edged with crimson, *Atalanta*, magenta crimson lower petals, with a small blotch in the top, and *Alabama* and *Gladiateur*, all four from Mr. Nye. Of *Zonale Pelargoniums* Mr. Windsor had Exhibitor, a broad-petaled salmon scarlet, *Pink of Perfection*, *Gladiateur*, pale salmon, *Great Eastern*, and *Sir Robert Peel*, bright scarlet; and Mr. Holland, *Rosalie*, a promising kind with large trusses. Beaton's *Nosegays* were again shown very successfully by Mr. W. Paul, with the addition of *Pillar of Beauty*, with large trusses of orange scarlet blooms; *Wiltshire Lass* by Messrs. Downie & Co.; *Petunia Illuminator*, a very pretty striped variety, by Mr. Clarke, *Streatham*; and *Double Tom Thumb Nasturtium*, by Messrs. Carter. Miscellaneous objects consisted of *Pinks* from Messrs. Turner, Hooper, Kingston, and Waymouth; *Pansies* from Messrs. Downie, Hooper, and others; cut flowers of herbaceous plants from Messrs. Paul & Son; hanging-baskets from Messrs. A. Henderson and Mr. Young; *Fuchsias* from Mr. Gardiner and Mr. Wheeler, gardener to Sir F. Goldsmid; and last, but not least, a beautiful collection of *Lilium auratum* from Mr. Turner. Some of the flowers had much more red in the bands than we have ever before seen, others were remarkable for their breadth of petal, and all for the size and beauty of the flowers.

#### FRUIT.

The show of fruit was tolerably extensive, especially considering the period of the season, and generally good.

**PINES.**—Of these but few were shown. There were two *Providences* of about 8 lbs. *Queens* though good did not appear to be heavy, the weights, however, were not stated.

**Prizes.**—For *Providence*: first, Mr. Ruffett, gardener to Lord Palmerston; second, Mr. Bailey; third, Mr. Masters. For *Queens*: first, Mr. Barnes; second, Mr. Godfrey; third, Mr. Standish and Mr. Stevens, Malvern Hall. For any sort: first, Mr. Bailey; second, Mr. Standish.

**GRAPES.**—Seldom have finer bunches of *Black Hamburgh* been seen than those from Mr. Fowler of Castle Kennedy. They were very even in size and berry, their weights being 3 lbs., 3 lbs. 1 oz., and 3 lbs. 2 ozs., giving for the three bunches 9 lbs. 3 ozs. Mr. Henderson took an equal first prize for excellent well-coloured bunches; and Mr. Meredith with one very large bunch and two of less size, though still splendid bunches, was second. Many fine bunches were likewise shown by other exhibitors. In *Black Prince* Mr. Hill, Keele Hall, and Mr. Meads, Minley Manor, this year, as last, out-distanced all competitors, and were placed equal first. Mr. Meads' bunches weighed 8 lbs. 14 ozs. Other *Black Grapes* consisted of *Trentham Black*, shown in fine condition by Mr. Meads; and good *Black Frontignans* from Mr. Allport. *Muscats* were all unripe, and no class being provided for them the Judges had a most difficult task in deciding on their merits as compared with other *White Grapes*, none of which will bear comparison with a ripe *Muscat*. They are either worthy of a class to themselves at this season, or they are not, and in the latter case it would be better to exclude them altogether, and award a higher prize at the July show. Many fine bunches were, nevertheless, shown with but the one defect of unripeness. Of other kinds there were good bunches of *Buckland Sweetwater*, and *Golden Hamburgh*, from Mr. Pottle and Mr. Fowler.

**Prizes.**—For *Black Hamburghs*: first, Mr. Fowler and Mr. M. Henderson; second, Mr. Meredith; third, Mr. Osborne and Mr. Clements; extra, Mr. Allen, Hopwood

Hall, and Mr. Wallis, Aste Park. For *Black Prince*: first, Mr. Meads and Mr. Hill; second, Mr. M. Henderson. For any kind: first, Mr. Meads; second, Mr. Pottle and Mr. Harwood; third, Messrs. Lane.

**PEACHES AND NECTARINES** were tolerably numerous, and some were very good. The principal *Peaches* were *Violette Hâtive*, *Royal George*, and *Noblesse*. Mr. Joyce took the first prize with large fruit of a kind to which no name was attached, supposed to be *Vanguard*, but doubtful. Mr. Allen was second, Mr. Sage third. For *Nectarines* Mr. Lynn, Hedsor, was first with *Violette Hâtive*, very fine; Mr. Holder second with *Elruge*; Mr. Turner, and Mr. Hill, Keele Hall, third. Remarkably fine boxes of *Peaches* and *Nectarines* came from Mr. W. Allen, the fruit being very even in size, and finely ripened.

Of other fruits *Melons* were numerous shown. The best *Scarlet-fleshed* were *Malvern Hall*, from Mr. Paton, gardener to Il. Lucy, Esq., *Charlecote Park*, and *Gem*, from Mr. Kaile. In *green-fleshed* Mr. Enstone was first with a hybrid; Mr. Pottle second with *Pottle's Green-fleshed*, a large yellow kind, mostly oval in shape. *Cherries* chiefly consisted of *May Duke*, *Black Tartarian*, and *Elton*. *Belle d'Orleans* and *Knight's Early Black* were also shown. Mr. Turner and Mr. Ruffett were first and second in the *Black* class, and Mr. Enstone and Mr. Dawson held similar positions in *White Cherries*. *Strawberries* were inferior to what we have seen in former years. *Sir Joseph Paxton*, *Sir Harry*, and *President* were among the best. Mr. Turner was first, Mr. Widdowson second, Mr. Pottle third. In *Figs* the best were the *Castle Kennedy*, from Mr. Fowler, and *White Marseilles*, which, though not equal to others in appearance, was excellent in flavour. Mr. Standish again exhibited his fine pot *Cherries*.

#### TODMORDEN BOTANICAL SOCIETY.

MONDAY, JUNE 5.

We noticed on the table several very interesting and rare British plants, both in the *phænogamous* and *cryptogamous* sections. Among the former we may name *Eriophorum alpinum*, and some fifteen or twenty specimens of *Saxifraga*. These last had an especial interest, as serving to show that the spotted-flower species, with a few exceptions, are confined to the entire-leaved section, those having more divided leaves being almost invariably wanting in that characteristic.

A series of some of the rarer British *Willows* was also noticeable, including *Salix reticulata*, *S. herbacea*, *S. repens*, and *S. pentandra*. With reference to this last species the Hon. Secretary remarked that it was a matter of some importance to know that the male plant was very distinct from the female as regards habit, &c., the latter being merely a straggling sub-tree, while the former grew to a much larger size.

Among *cryptogams*, fronds were exhibited of a magnificently ramulose *Lady Fern*, lately discovered by Mr. James Law, of the Vale Nurseries, having at least a hundred fronds upon it, every one of which is branched; certainly one of the best "finds" we have recorded in this neighbourhood for some time back.

#### HARDY ROSES.

THESE *Roses* wintered out of doors well, and are beautiful for growth, foliage, buds, and blooms, and may be advantageously bought or propagated to any amount.

1, *Madame Victor Verrier*, A1; 2, *Pierre Notting*, A1; 3, *La Duchesse de Morny*, A1; 4, *Eugène Verrier*, very fine; 5, *Baronne P. de Kinkelin*, very fine.

They are rightly described in the catalogues. In due time I shall speak of these and others more fully.—W. F. RADCLIFFE, *Tarrant Rushton*.

**BRIGHTON AND SUSSEX HORTICULTURAL SOCIETY.**—The summer Show, which scarcely yields in interest and extent to the greatest of our metropolitan exhibitions, is to be held on the 28th and 29th inst., in the rooms and grounds of the Pavilion, a building admirably adapted for the purpose. The schedule is very liberal; and there are no less than

sixty-five classes, thirty-six of which are open to all England, the others to those residing in Sussex only. Intending exhibitors should send notice to the Secretary, Mr. E. Carpenter, 96, St. James's Street, Brighton, of the classes in which they purpose showing, before Saturday, the 24th inst.

### STOPPING VINE SHOOTS—SYRINGING.

I CONSIDER that no general rule can be laid down for stopping Vines on the spur system when showing fruit. It is, therefore, necessary for me to say why I think so. If a shoot is strong it will require stopping nearer home than a weak one does, and the strong-growing kinds throughout will require somewhat different treatment from the more delicate kinds. For instance: some of the Sweetwaters require different treatment from the Muscat of Alexandria, and pot Vines in all cases require a management different from that for those planted out. No doubt Mr. Wills is quite right in saying that the leaves are the mouths to feed the Grapes; but let us bear in mind that if a master of a family had more mouths than he had food to put in them the whole family would suffer, and let us try to apply this to the case before us.

Let us first look at the pot cultivation (and, by-the-by, Mr. Wills does not tell us, but I infer he alludes to Vines planted out), and pot cultivation is now extensively practised, and well deserves attention. A successful grower will find it necessary to adopt Mr. Wills's views in stopping with two leaves; indeed, in some instances I would not stop at all until the fruit were set, and the bunch fully formed and thinned; but when luxuriant growth is going on with planted-out Vines I have experienced that stopping at the very eye where the bunch is will be productive of the best fruit, and I think reason will bear us out on this point. Cut short in the way described, the sap or food, of course, flows immediately to the apex of the shoot or bud. For a week or so there is nothing to feed but one leaf and the bunch, and in a very little time the apex bud will burst, and we can then give one or two leaves as circumstances require—not that I follow this strictly, but I do in some instances, and in all cases one eye only above the bunch.

Mr. Wills and myself differ *in toto* as to syringing after the Grapes are set, and whilst I am in opposition to your correspondent, I know I am at drawn swords also with the great Vine-grower Mr. Thomson, of Dalkeith. Of course no one would think of syringing whilst they were in flower, but after they are nicely set, about thinning time, most decidedly I say syringe (in hot weather after the sun has left the house), not only the floor and walls, but the Vines, leaves, fruit, glass, and every part of the house. I will offer a proof that I am right, too, to those who choose to avail themselves of the opportunity to see the houses here. Two years ago, when I came to this place, the houses were all new, the Vine-border well made under the eye of an experienced Vine-grower, and young Vines had been planted out about six weeks, but were very badly attended to, consequently had not made a move after being planted; even the young leaves were turning yellow. A particular acquaintance of mine and one of the best Vine-growers in the kingdom, Mr. Burton, at the Marquis of Salisbury's, saw them in that stage; his opinion was that they were completely ruined. I had my own thoughts upon the matter; I could see they had been kept quite dry. I set to work, had the inside border well saturated with water, kept the house a little shaded from the burning sun (the month of June), I cut the Vines in to one of the most prominent eyes I could find, and wrapped the Vines in damp moss, and the house was syringed night and morning. The result was in about a fortnight the top bud began to show vitality, in three weeks burst, and by the end of summer the canes had reached the top of the house. Mr. Burton saw them again in the autumn, but could scarcely credit they were the same Vines. The following season—namely, last year—I allowed them to bear a bunch or two, and here again I am at variance with Mr. Thomson. This year I am fruiting them from the bottom to the top of the house. They are now in vigorous health, those in one of the houses just changing colour, and have been treated up to this time as before described, having had the syringe at work without intermission. The foliage is

green and healthy, the berries well swollen and free from rust and spot of any description.

I consider attempting to aid fertilisation useless. I had a house (pot Vines) in bloom in the beginning of January last, the worst time of the year; I never used any artificial means to assist the fructifying pollen. The flowers are hermaphrodite, and the anthers are so connected with the stigma of the pistil that there is no need of any assistance. The bunches I am speaking of here all set, and have long since been cut, and now a second batch of pot Vines is fruiting in the same house.—ALFRED WHITTLE, *Gardener, Bush Hall, Hatfield, Herts.*

### THE NEW EARLY PEAS.

In the spring of this year it was proposed by Messrs. Carter that the early Peas should be carefully tried and proved under our superintendance, at Waterloo Nursery, Kilburn, a fine open spot of ground, with a subsoil of stiff clay. We communicated our intention to Messrs. Sutton, of Reading, and Messrs. Dickson, of Chester, and they both kindly forwarded true stocks of their early Peas, and Messrs. Fairhead hearing of the experiment, also wished their varieties to be tested. We procured Carpenter's Express, and Dillistone's Early Prolific, from the raisers. The Peas were all sown on the 15th of March, one long row of each, side by side, of the following named sorts:—Sutton's Ringleader, Fairhead's Conqueror, Dillistone's Early Prolific, Carter's First Early, Fairhead's Railway, Sangster's No. 1, Carpenter's Express, Fairhead's Hardy's Early, and Dickson's First and Best Early. The following five varieties—Dillistone's Early Prolific, Sutton's Ringleader, Carter's First Crop, Fairhead's Conqueror, and Fairhead's Railway, all proved to be identical; in fact, so much so, that they all appeared the same, both in height (2 feet), time of flowering (13th of May), colour of the foliage, style of growth, measurement of the pods, their shape, number of peas contained in the pods, the peculiar property of all these five sorts, in producing a mass of pods from the bottom to the top of the haulm, and in the whole crop being fit for use simultaneously. The entire row if need be can be gathered and used the same day; again, the flavour in all is alike. We must, therefore, so far as our trial and judgment are concerned, remark that, throughout all the stages of their growth, there cannot be found a shade of difference; we, therefore, consider that honour should be given to whom it is due, and that Mr. Dillistone has the merit of sending out the earliest Pea known.

We now come to Sangster's No. 1, Dickson's First and Best Early, Carpenter's Express, and Fairhead's Hardy's Early, these we treated exactly alike, one long row of each variety planted side by side. Excepting that Sangster's No. 1 and Carpenter's Express have flowers of a whiter colour, there is absolutely not the shadow of a difference between these four sorts. They are the same in height (3½ feet), were in flower May 20th; style of growth, flavour of the peas, shape of pods, all alike. One noticeable feature in these varieties is, that several successive gatherings may be made day after day. These four sorts are quite ten days later, under ordinary cultivation. The five early varieties were fit for use June 3rd; these four later sorts not until the 13th. No doubt much depends upon locality, snug and warm borders, dry subsoil, and other similar contingencies.—A. HENDERSON & Co., *Fine Apple Place, Edgware Road.*

PERMIT me to say a few words respecting early Peas. I sowed Mr. W. Paul's Tom Thumb in a gentle heat on the 20th of February, planted out the young plants on a south border on the 20th of March, and gathered on the 23rd of May.

Carter's First Crop variety was sown on the same day, and I treated the plants precisely the same in every respect. I gathered from them on the 29th of May.

Sangster's No. 1 sown at the same time, and treated precisely the same in every respect, were gathered from on June 4th. Therefore, I consider Mr. W. Paul's Tom Thumb the earliest Pea we have.

Another excellent quality in favour of Tom Thumb is, it requires no sticks. The plants grew with me about 1½ foot high, and although they commenced fruiting at the time

I have named, they are at this moment covered with flower; the case is quite different with the two other varieties named, for they have both done bearing, and not a bloom is to be seen on them.—J. HILL, *The Gardens, Poles, Ware, Herts.*

NOTICING several communications respecting the earliest varieties of what are called new kinds—viz., Dickson's First and Best, Sutton's Ringleader, Carter's First Early, Carpenter's Express, Essex Rival, Dillistone's Early, and Sangster's No. 1, a trial was undertaken on purpose to prove which is the earliest. Two rows of each were sown on the 7th of February on a south border, and treated exactly the same.

Dickson's was the first to flower and to be gathered from; all the pods, too, were double. It is a kind quite distinct from any of the others. Next came Sutton's Ringleader, Dillistone's Early, and Carter's First Early. These three I consider the same variety, mostly single-podded, and all of the same height.

Next came Carpenter's Express and Sangster's No. 1. These two are decidedly the same kind.

The latest of all was Essex Rival, 4 feet.

The only kinds I intend to grow for early crops are Dickson's First and Best Early and Sangster's No. 1.—E. WELCH, *Palace Garden, Armagh, Ireland.*

### WINTERING PLANTS IN A ROOM.

It may, perhaps, interest some of your readers who, like myself, have a small garden, but no greenhouse, pit, frame, or other convenience for wintering plants, to hear that I have now in my garden the following, all wintered in a room—viz., 33 scarlet Geraniums, 8 white Geraniums, 3 Fancy Geraniums, 45 yellow Calceolarias, 3 Lobelias, 1 Verbena, and some old plants of Calceolarias, scarlet Geraniums, and scented Verbenas. Excepting the old plants, the whole are cuttings made by myself as nearly as I could according to the directions given from time to time in your Journal. During the winter they were on shelves across one window only. This window is in a room which never once had a fire in it, and which faces the east; it is also shaded from the south by a projecting part of an adjoining house. I was able to attend to them myself nearly the whole of the time.

In addition to what I saved there were a number more which died, mostly Verbenas and Lobelias, these, as I suppose, not requiring the same treatment as the others; but from the very small means at my command I was only able to give one sort of treatment to all. The dry air of a room was not very favourable for raising cuttings at all. Next winter I hope to try again, and by making cuttings only of those sorts which did best, to save a larger proportion of plants.—V. G. C.

### REPORT ON THE BEDDING PELARGONIUMS GROWN AT CHISWICK, 1864.

By THOMAS MOORE, F.L.S., SECRETARY TO THE FLOEAL COMMITTEE.

#### SERIES II.—ZONATE VARIETIES.

(Continued from page 451.)

#### 3. FLOWERS SALMON OR FLESH-COLOUR.

*Auricula* \*\* (Bull).—Moderately vigorous; leaves dark zoned; flowers shaded salmon, rather effective. It also proved free and good, deserving of two marks, as grown under glass.

*Aurora* \*\*\* (Hally).—Dwarf habit; leaves distinctly dark zoned; flowers free flesh colour.

*Chione* (Rollisson).—Moderately vigorous habit; leaves with dark zone; flowers flesh colour with deeper centre.

*Enamel* (Hally).—Moderately vigorous habit; leaves darkly zoned; flowers of a deep salmon flesh colour with a white eye.

*Enchantress* (Bull).—Vigorous habit; leaves broad, with a dark zone; flowers deep flesh colour. Indifferent under glass.

*Ernest* (Bull).—Moderately vigorous habit; leaves with dark vandyked zone; flowers showy, of good form, deep flesh colour.

*Fanty* \*\* (Bull).—Moderately vigorous; leaves with dark zone; flowers flesh coloured with deeper salmon eye, freely produced and showy.

*Madame Chardine* (Low & Co.).—Vigorous habit; leaves with dark zone; flowers flesh colour with deeper centre.

*Madame Lemoine* (Bull).—Moderately vigorous; leaves with an indistinct zone; flowers pale salmon pink.

*Prince of Hesse* \*\* (Ingram).—Moderately vigorous habit; leaves with dark zone; flowers salmon pink with deeper centre.

*Prince of Wales* (E. G. Henderson & Son).—Moderately vigorous habit; leaves dark zoned; flowers salmon colour, paler at the edge.

*Princess Mary* \*\*\* (The Society).—Vigorous habit; leaves broad and flat with a very broad dark zone; flowers in the way of those of Prince of Hesse, shaded salmon pink, of fine form, and produced in good trusses. A seedling raised at Chiswick.

*Rosamond* \*\* (Bull).—Moderately vigorous habit; leaves with broad dark zone; flowers free, the trusses compact, the blossoms deep salmon pink, of fine shape.

*St. Fiacre* \*\*\* (Salter).—Rather dwarf habit; leaves with a deep dull zone; flowers abundant, salmon pink, deeper in the centre. Also free, showy, and of the first quality as a pot plant.

*Souvenir du 8 Juin* \*\* (Van Houtte).—Rather dwarf in habit; leaves marked with a dull zone; flowers freely produced, flat, and of good form, salmon pink, deeper towards the centre, which forms a small pale eye. This was only grown as a pot plant, and received two marks for its quality under glass.

#### 4. FLOWERS WHITE.

*Eugène Dufoy* (Carter & Co.).—Vigorous habit; leaves with broad dull zone; flowers blush white. Of no particular merit under glass.

*Flag of Truce* (Wills).—Vigorous habit; dark-zoned leaves; flowers blush white.

*Lady Blanche* (Salter).—Moderately vigorous habit; leaves with a dark vandyked zone; flowers blush white.

*Madame Cornelissen* (Salter).—Dwarf habit; leaves dark zoned; flowers white, with a broad salmon eye.

*Madame Vaucher* \*\*\* (Low & Co.).—Vigorous habit; leaves with dark zone; flowers in good trusses, white, changing to blush. The most useful of the whites grown in the collection.

*Purity* (Bull).—Vigorous habit; dark-zoned leaves; blush white flowers. It proved a shy bloomer under glass.

*Snouball* (Carter & Co.).—Dwarfish vigorous habit; leaves dark zoned; flowers white, in the way of Mrs. Vaucher, but the plants were not in character. It bloomed better in pots but the flowers were set too close down to the leaves.

*The Swan* (Bull).—Vigorous habit; leaves with dark vandyked zone; flowers white, in large trusses, sometimes showy. Under glass it bore long-stalked trusses, and was in some states a rather desirable variety.

*White Perfection* \*\*\* (J. F. Chater).—Vigorous habit; leaves marked with a broad zone of dull brown; flowers blush white. Under glass this proved of the first quality, as indicated by the above marks; the flowers being pure white, of good shape, and thrown well up.

#### 5. FLOWERS WHITE OR PALE-COLOURED WITH SALMON EYE.

*Amelina Grisau* \*\*\* (Salter).—Moderately vigorous habit; leaves marked with a broad dark zone; flowers large, of fine shape, white, with a bright salmon eye. Altogether a very fine sort, with the colours bright and well-defined.

*Beauty* \*\*\* (E. G. Henderson & Son).—Moderately vigorous habit; leaves marked with a dark zone; flowers of very fine shape, white, with a salmon-coloured eye, forming an edging to the base of the petals. One of the best of the race.

*Bel Demonio* (Carter & Co.; Williams).—Vigorous habit; leaves with broad brown zone; flowers with salmon-coloured centre. It proved to be shy both out of doors and under glass.

*Display* (Williams).—Moderately vigorous habit; leaves with broad dark zone; flowers white, with salmon eye.

*Erin-go-Bragh* (Bull).—Moderately vigorous habit; leaves marked with a broad dark zone; flowers white, with salmon eye.

*Eugénie Mezard* \*\*\* (Salter, E. G. Henderson & Son, Turner).—Moderately vigorous habit; leaves with a broad dark zone; flowers white at the edge, with salmon centre, showy, well-formed, and produced in good handsome trusses. This was received also under the name of Madame Rudersdorff. It was of the first degree of merit as a pot plant.

*Eva* (Bull).—Vigorous habit; leaves with broad dark zone; flowers white, with pink eye.

*Fascination* (Williams).—Moderately vigorous; leaves with a dull zone; flowers salmon, paler at the edges.

*François Desbois* \*\*\* (E. G. Henderson & Son).—Moderately vigorous habit; leaves with a dark submarginal zone; flowers white, with a bold, deep, salmon eye, freely produced. A good pot plant, but not equal to Amelina Grisau.

*Henri de Beaudot* (Low & Co.).—Vigorous habit; leaves dark zoned; flowers white, with deep salmon centre.

*Léonie Nivelet* \*\*\* (Van Houtte).—Moderately vigorous; leaves broad, marked with a dark zone; flowers of good form, white, with salmon eye, in fine trusses. It proved also to be a first-rate pot plant, with fine elevated trusses of salmon-flesh flowers, paler and whitish towards the edges.

*Loveliness* (Wills).—Moderately vigorous; leaves dark zoned; flowers salmon, with pale edges.

*Marie Labbe* \*\* (Van Houtte).—Moderately vigorous; leaves with a dark centre or zone; flowers of fine shape, white, with a pink eye formed by markings at the edge of the petals near their base; it resembled Beauty.

*Mrs. Moore* (Wills).—Vigorous habit; leaves dark zoned; flowers white with salmon eye.

*Nelly* (Bull).—Vigorous habit; leaves with very broad dark zone; flowers white, with salmon eye. It proved a good free-blooming pot plant, in the way of Eugénie Mézard, but too much resembling it to be also required.

*Neptune* (Bull).—Vigorous habit; leaves marked with a dull zone; flowers white, with salmon eye.

*Pauline* (Bull).—Vigorous habit; leaves marked with a broad black zone; flowers white, with salmon eye. Tolerably effective under glass.

*Pretty Polly* (Wills).—Moderately vigorous; leaves with a dark centre or zone; flowers white, with pink centre.

6. FLOWERS ROSE PINK.

*Aglaia* (Salter).—Vigorous habit; leaves with broad dull zone; flowers of good shape, rose-pink, white at the base.

*Amy* \*\* (Rollisson).—Vigorous habit; leaves with a dark vandyked zone; flowers in fine trusses, large, pale rose pink, with a white base.

*Chancellor* (Bull).—Moderately vigorous habit; leaves with an indistinct green zone; flowers rose pink, with a white base.

*Charmer* (Bull).—A good rose pink, paler than Madame Cassier. It was only grown as a pot plant.

*Eve* \*\*\* (Bull).—Of rather vigorous habit; leaves marked with a broad dull zone near the centre; flowers large, in large trusses, of fine shape, light rosy pink with white base. A very fine pale variety in the open borders, and of nearly equal merit as grown in pots.

*Flora* \*\*\* (Van Houtte).—Moderately vigorous habit; leaves with an indistinct green zone; flowers large, pale rosy pink or peach, white at the base, and of fine shape. A fine, large, pale peach-coloured sort, grown only under glass, under which conditions it was of first-class quality.

*Helen Lindsay* \*\*\* (Carter & Co.).—Of rather vigorous habit; leaves with a broad indistinct zone near the centre; flowers abundant, in fair-sized trusses, deep bright rose pink. A very lively and bright-coloured variety.

*Madame Cassier* \*\* (Van Houtte).—Moderately vigorous habit; leaves broad and very flat, marked by a dark zone; flowers deep rose pink, with white base, and of good shape. Under glass it was of second-rate merit, and the leaves became indistinctly zoned.

*Minnie* \*\* (Rollisson).—Moderately vigorous habit; leaves with a dark zone; flowers in good trusses, pale rose pink with a white base.

*Mrs. Whitty* (Carter & Co.).—Moderately vigorous habit; leaves marked with a dull, broad, unequal zone; flowers deep rose pink, white at the base. Much in the way of but not so good as Helen Lindsay.

*Rose Rendatler* \*\*\* (Downie & Co.).—Moderately vigorous habit; leaves with a dark vandyked zone near the centre;

flowers lively rose pink, with a white base, of good shape, and borne in compact trusses. A fine sort both for beds and pot culture.

*Roseum Nanum* (Salter).—Dwarf, free habit; leaves dark zoned; flowers of good shape, rose pink, white at the base. A useful free-flowering variety.

SERIES III.—MARBLED-LEAVED ZONATE VARIETIES.

*Dayspring* (Dixon).—Moderately vigorous habit; leaves with yellowish green radiating centre, and no dark zone; flowers deep scarlet. A rather pretty variety, and quite distinct in its foliage.

*Lady of Lovetto* (E. G. Henderson & Son).—Moderately vigorous spreading habit; marbled leaves; flowers cerise-scarlet.

*Pigmy* (Hally).—Dwarf habit; leaves marbled; flowers scarlet.

*Prince Arthur* (Hally).—Moderately vigorous spreading habit; leaves marbled and very darkly zoned; flowers light scarlet.

*Rose of Lee* (Hally).—Vigorous habit; leaves marbled; flowers cerise scarlet.

*Sheen Rival* \*\*\* (Kinghorn).—Moderately vigorous habit; leaves darkly zoned and marbled with light green; flowers bright light scarlet, of good form, in fine trusses.

SERIES IV.—NOSEGAY VARIETIES.

I. LEAVES ZONATE.

*Beaton's Pet* (Carter & Co.).—Very dwarf habit; leaves marked with a dull zone; flowers loose, in small trusses, of a bright rosy crimson. The plant was in a weak condition.

*Carminatum Improved* (Carter & Co.).—Moderately vigorous habit; leaves indistinctly zoned; flowers crimson magenta.

*Carmine Nosegay* (E. G. Henderson & Son).—Moderately vigorous habit; leaves with a faint narrow green zone; flowers deep cerise, in moderate trusses.

*Cybister* \*\*\* (Carter & Co.).—Full vigorous habit; leaves large, with dull olive zone; flowers in large trusses, well thrown up, narrow petaled, scarlet. It is of a very effective colour, brighter and lighter than Stella, but with longer and narrower petals.

*Imperial Crimson* (Turner).—Dwarf spreading habit; leaves with a faint narrow green zone; flowers loose, narrow-petaled, in small trusses, magenta rose.

*Lady Cullum* \*\* (Carter & Co.).—Dwarf habit; leaves marked with an indistinct zone; flowers free, loose, lilac pink, with a white base.

*Lord Palmerston* \*\* (Carter & Co.).—Dwarf and moderately vigorous habit; leaves with very faint zone; flowers in small trusses, the plant being weak, cerise-scarlet, changing to magenta.

*Madame P. Gaspard* (Salter).—Moderately vigorous habit; leaves with an indistinct green zone; flowers thin and loose, deep rose pink.

*Magenta* \*\* (E. G. Henderson & Son).—Vigorous habit; leaves broad with a darkish vandyked zone; flowers distinct and showy, of a semi-nosegay character, the trusses thrown well up, and freely produced. Approved chiefly for colour.

*Merrimac* \*\*\* (Salter).—Moderately vigorous habit; leaves with a broad dull zone; flowers in immense heads, deep cerise or carmine rose, the blossoms broad-petaled for one of the nosegay race. It was grown only in pots, and was in this way quite first-rate.

*Merrimac* \*\* (Carter & Co.).—Moderately vigorous habit; leaves with narrow olive zone; flowers broad-petaled, in moderate trusses, cerise rose.

*Monitor* \*\* (Carter & Co.).—Rather dwarf spreading habit; leaves lobed, with a dull brown zone; flowers large and broad for one of the nosegay race, dull orange scarlet. Desirable from its colour.

*Red Nosegay* (Taylor).—Moderately vigorous habit; leaves with faint narrow green zone; flowers cerise scarlet, in moderate trusses.

*Rival Nosegay* (Carter & Co.).—Moderately vigorous habit; flowers large and broad-petaled as a nosegay, in good trusses, of a deep magenta shaded with crimson. Not one of the semi-nosegay race.

*Stella* \*\*\* (E. G. Henderson & Son).—Vigorous habit; leaves with dark zone; flowers in bold trusses, broader-petaled than Cybister, and of a deeper scarlet. One of the finest of all Pelargoniums for effect.

## 2. LEAVES VARIEGATED WITH WHITE.

*Variegated Nosegay* \*\*\* (Turner).—Moderately dwarf habit; leaves whitish at the edge, cupped; flowers abundant and effective, but loose, cerise pink.—(*Proceedings of the Royal Horticultural Society.*)

(To be continued.)

## STOPPING NEWLY-PLANTED VINES.

I PLANTED in the early part of February six strong Vines, every shoot showed fruit, which I, of course, took off. These Vines have now reached half way up the lights, and are looking strong and flourishing. A gardener advised me to stop the leading shoot, but my own impression is, that the leader ought to be allowed to reach the end of the light, and then be stopped some time in August. Another question I would wish to ask is, Whether the tendrils of the leader should be taken off?—H. R. DU PRÉ.

[Stop the Vines when they have reached about three parts of the way up the rafters. It will cause them to grow more robust from the base and upwards than when the cane is allowed to grow to the top of the house before stopping. It often happens, in consequence of the sap always flowing to the highest point first, that the Vine swells out largely when it is about half way up the house, whilst from that point downwards it has a very pinched appearance, the stopping is, therefore, necessary to cause the Vine to grow more proportionate. It also helps the ripening process gradually from the base upwards after the first stopping. As soon as the Vine has grown about 3 feet stop it again, and as soon as it reaches the top of the house, stop it again. The tendrils should be pinched out, and the laterals should be stopped at the second leaf.]

## PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

*CYPEPIDIUM CONCOLOR* (One-coloured Lady's Slipper).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—Native of Moulmein. Flowers lemon-coloured. Leaves beautifully variegated with rows of crescent-shaped dark green spots.—(*Bot. Mag.*, t. 5513.)

*VELLOSIA CANDIDA* (White Vellosia).—*Nat. ord.*, Hæmodoraceæ. *Linn.*, Polyadelphia Polyandria.—Native of Brazil.—(*Ibid.*, t. 5514.)

*DENDROBIUM HEDYOSMUM* (Sweet-scented Dendrobium).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—Introduced from Moulmein, by Messrs. Low & Co., Clapton Nursery. Flowers white with orange lip; scented like the Wallflower.—(*Ibid.*, t. 5515.)

*ACANTHUS MONTANUS* (African Mountain Acanthus).—*Nat. ord.*, Acanthaceæ. *Linn.*, Didynamia Angiosperma.—Native of Fernando Po. Flowers lilac.—(*Ibid.*, t. 5516.)

*RAILLARDIA CILIOLATA* (Ciliate-leaved Raillardia).—*Nat. ord.*, Composite. *Linn.*, Syngenesia æqualis.—Native of Hawaii, one of the Sandwich Islands, at an elevation of 10,000 feet. Flowers yellow, with prominent crimson anthers.—(*Ibid.*, t. 5517.)

*ANEMONE (HEPATIC) ANGULOSA* (Angle-leaved Hepatica).—*Nat. ord.*, Ranunculaceæ. *Linn.*, Polyandria Polygynia.—Native of Hungary. Flowers purplish-blue. Anemone Falconeri, recently discovered in Kashmir, so closely agrees with Hepatica in almost all essential characters, that the last-named genus has been abolished.—(*Ibid.*, t. 5518.)

*RHODODENDRON*.—*Princess Alexandra*, a cross between *R. jasminiflorum*, and a species never sent out. Raised by Messrs. Veitch. White with a pink tinge.—(*Floral Mag.*, pl. 245.)

*ZONALE GERANIUM*.—*Venus* (Halley's). Raised by Mr. Halley, nurseryman, Blackheath. Awarded a first-class certificate by the Royal Horticultural Society. Dwarf and compact; flowers bright scarlet. Leaves yellowish green centre, black zone, and dark green margin.—(*Ibid.*, pl. 246.)

*HEPATIC ANGULOSA*.—See above, *Anemone angulosa*.—(*Ibid.*, pl. 247.)

*DOUBLE-FLOWERED MIMULUS*.—Raised by Mr. Bull. Orange and yellow with dark crimson spots and blotches.—(*Ibid.*, pl. 248.)

*PELARGONIUM*.—*Amy Hogg*. One of the late Mr. Donald Beaton's seedlings, and now possessed by Mr. Wm. Paul, Waltham Cross Nursery, and one of the best of the series. Truss large, deep carmine; leaves with a dark green zone; plant strong-growing and spreading.—(*Florist and Pomologist*, iii., 113.)

## MY PLANTS,

AND HOW AND WHERE I FOUND THEM.—No. 4.

"The increasing blast roared round the beetling rocks;  
The clouds, swift-winged, flew o'er the starry sky."

We will now quit for a time the wild and romantic hills and dales of North Staffordshire, with their picturesque scenery and immense resources of mineral wealth; we will take leave of its towns, with their numerous manufactures, for an exploring tour in the neighbouring island of Jersey. I would, however, advise intending travellers to select the calm and bright summer months for their trip, and not expose themselves to the vagaries of the tides or the violence of the storms in this part of the Channel, as we did at so inclement a time of the year as January.

It was an eventful evening, that in 1860, on which we quitted London, and securing a railway carriage for our own and children's exclusive benefit, were whirled away through the unsatisfactory and mysterious darkness of the night, right onward to the port of Southampton. The bairns, warmly ensconced in railway rugs and shawls, slept soundly. Childhood's happy confidence, and full trust in the protecting care of the parents who journeyed with them, dispelled all fear of the noise and darkness which surrounded them. Let us look for a moment at their peaceful faces by the small light of the carriage lamp, and learn that difficult lesson of faith and trustfulness in the Universal Father in those dark days which come more or less to all earth's children, and more especially do I address my own sex; for

"Do I not know  
The life of woman is full of woe?  
Toiling on and on  
With breaking heart, and tearful eyes,  
And silent lips, and in the soul  
The secret longings which arise,  
Which this world never satisfies!  
Some more, some less, but of the whole  
Not one quite happy—no, not one!"

Still, in the midst of it all, "*Nil Desperandum*" is a very good motto for a good wife, and also for a good Christian. *Nil Desperandum!* Hope on, Hope ever! and have the children's trust on your journey through life, and you shall have also their calm awaking at the end of it.

Immediately after our arrival at Southampton we found ourselves on board the steamer appointed to convey us to the island of Jersey, which island we hoped to reach at day-break. In consequence of the roughness and severity of the weather the mails had been detained in Southampton the previous night, and many were the surmises as to whether our boat could with safety make the passage even then. The captain, however, was determined to run across; and my husband, the greater part of whose youth had been passed at sea, only saw a night of pleasant excitement before him, and cordially joined the captain in his wish to proceed. What was a storm to him?—he who could sit as comfortably whistling upon the mainyard as chatting in the easy chair at home. So the steam was got up, and away we started. Never shall I forget my first apprenticeship to the sea, or how dearly I "paid for my footing" within the realms of Neptune. Having quietly demolished one's chicken pie and visibly decreased the ham, how pleasant to sit with one's feet on the fender, and having discussed the births, marriages, and deaths in the morning paper in genuine feminine style—read everything, in fact, excepting the columns devoted to politics, and even if it is a wet morning condescended to peep at these—we turn over the paper, and our eye catches the advertisement, "To Jersey and Back," "To St. Malo and Back," &c., for some nominal sum. How smoothly flow the words! and no sooner have you read this invitation than in imagination you are borne on the back of "the swallow flying south" to the "gilded eaves" of some fair one in this island of warmth and love. But it is a very different thing to picture all this so prettily, or even (to revert to the gilded gingerbread), to sympathise with the

gallant crew of a weather-beaten boat, or to read of the glorious struggle of men and bark, both fighting the fight of the winds and the waves, and of their timely deliverance, of the cheer of welcome and "thank God" feeling which greeted the well-nigh failing hearts and hands as they quitted their boat for the friendly shore. It is a different thing, I say, to picture all this in one's mind's eye, and to experience the same yourself. I had made up my mind to eschew all threatenings of such a vulgar attack as sea-sickness. I have a great opinion of the superiority of mind over matter, and of the influence which a strong and well-regulated will has over our physical infirmities; so much do I feel satisfied of the truth of this theory, that were this the place for such a discussion I would strenuously urge upon young mothers to act upon this suggestion themselves, for the future well-being of those who have not as yet seen the light. If children naturally inherit the hasty temper, the untidy habits, the loose principles, &c., of the parents, surely by the mother's strict watchfulness to curb her own temper, to be exact, methodical, kind-hearted, checking in herself frivolous thoughts and actions, she has done much to make her offspring a great and good man or woman.

But I am moralising instead of pursuing my account of the bodily sufferings which we underwent. Pain certainly can be borne with courage and a certain amount of placidity; but as the Staffordshire people would say, "My word!" it might be "a caution to the Greeks," when sailors who have been inured to all weathers from childhood begin to make preparations for a hurricane in the Channel, and to wonder and speculate upon how many hours the mails will be delayed. It considerably lessens the firmness with which you entered your cabin—queer feelings and qualms come over you; and in spite of your sternly-believed theory with regard to the mental powers, you are helplessly engulfed in that horror of horrors—sea-sickness. I must do the stewardesses of the Channel-island boats the justice to say that on all subsequent occasions I found them civil and attentive; but in the present instance we fell into the hands of a cold-blooded ogress, who evidently thought that all possible discomforts and illnesses were the proper accompaniments to a trip to the islands, and all the fees she could get her own just due for the pleasure which her society might afford us. The children she treated like trespassing dogs or cats, and disposed of them as quickly as possible in the various little snuggeries within her den. This done, and a basin given to each lady, she seemed to consider her duty accomplished, and immediately solaced herself with something, to which, assisted by our olfactory nerves and the vision of a black bottle, we gave a deep meaning. I have no doubt she herself became painfully aware of the all-powerful influence of this dark spirit upon her when, about a fortnight after the date of which I am writing, she fell from the companion ladder and broke her leg. Be still, revengeful heart of mine! What if she did take your baby of two months old from you, and, stowing it away as if it were some part of the luggage, lay it in its narrow quarters at the side of the ship, and in spite of your entreaties and helpless condition, refuse to bring it to you! What if in that fearful storm you vainly asked her to see to the safety of the child! What if her reply still rings in your motherly ears—"What business had ladies to bring babies at all out on such a night as this for? She'd answer for it, it wouldn't want rocking—the ship'd do that for it. Babies never came to any harm!" Do you feel a smack of pleasure that retribution so quickly followed her? Be still, revengeful heart of mine! An officer's lady threw herself just before the entrance to the place where "my darling lay sleeping," and I saw no more of it until the day dawned.

Prostrate and helpless I lay upon the floor of the ladies' cabin with a pillow for my head. My husband, although a medical man, was not allowed to enter this sanatorium, although he several times offered his services. For the first two hours after going on board I could manage to get into the saloon, but I soon got past that. Upon making some remark as to the roughness of the weather, his answer was very short—"Yes, it's blowing hard; it's what the sailors call a 'stinker.'" This last inelegant but expressive word awoke all my fears. The ship creaked, and strained, and creaked again. Boom went a wave on the right side, and down went the ship on the left; up she came again, and

creak went the planks. I began to think of all my relations, and to wish I had taken leave of them before joining the shrimps and mermaids. Just as I was thus pondering, away went all the basins to the other side of the vessel, and in an instant after back they rolled again. The cabin lamp went out, and we were all left in perfect darkness. A noise overhead reminded us that we were still in the land of the living, and not in the shades of which Dante speaks. The cabin door had been closed, but the stern stewardess entered—she whose heart relented only before the black bottle and its attendant spirits. Commenting upon the weather in no very choice terms, she relit the lamp. I asked what they were doing up above. "Oh, only covering the skylight, because the sea washed over it, and it might come into the cabin." *Might* come into the cabin! Then there was a possibility of our going to the bottom. I felt already as if I were slowly, slowly sinking. I thought of Miss Edith, and of Uncle 'Zekiel's speech to her when in much the same predicament: "I'm everlasting sorry I took you away from your father. You'd been a sleepin' safe and sound in your silk coverlids there instid of being pitched about by this infernal tempest."—ALICE.

### NEW BOOK.

*A Handbook of British Plants, designed especially for Schools, Science classes, and Excursionists.* By W. LOWNDES NORCUTT. London: Longman & Co.

THIS is a very well planned, correct, small, and cheap book. It is a good teacher how to recognise a plant, yet may be found useful even by a professed botanist, if he has it in his pocket during his rambles after plants. We recommend it to our readers, and the only improvement we can suggest is the addition of those great facilitators of reference, an index of the generic names, and another of the English names.

### ZINC LABELS AND INK.

THE French chemist Braconnot made the recipe of an indelible ink, known to write on zinc. It consists of one part crystallised verdigris, one part of sal ammoniac, and half a part of lamp-black, thoroughly mixed and pulverised. To this powder must be added ten parts by weight of distilled or rain water. It is the ink recommended in pomological books and journals. Sometimes the direction is given to keep the bottle always inverted, in order to prevent the ammonia from escaping. Any one who understands the alphabet of chemistry knows that this is poor advice, based on ignorance; there is no gas in the mixture ready to escape.

Dr. Rudolph Boettger, of Frankfort, of gun cotton notoriety (Boettger and Schoenbein), was the first in Germany that called the attention of nurserymen and pomologists to it, in his contributions to natural philosophy. This took place as early as 1837. The author showed that lamp-black is of no use whatever in the mixture; it ought, therefore to be omitted, being unfit to be incorporated in it, and having nothing to do with the colour of the ink. This was in 1841.

It is true that the ink is indelible, but it is grey instead of black. It requires, besides, if not much at least some skill in chemical manipulations, and a mortar for trituration; it is also somewhat expensive.

Being very fond of both natural philosophy and chemistry, I was, a number of years ago, engaged in some galvanoplastic experiments, when I had occasion to prepare Braconnot's ink. I disliked its colour, and, after some reflection on the cause of its action on the zinc, I concluded to try solutions of other salts of copper, and it was natural that I should dip my pen immediately in the solution of sulphate of copper used for my galvanoplastic experiments. Those conversant with such experiments will know that the solution contained a small quantity of free sulphuric acid. I was not a little astonished to behold the jet black colour of the letters written with it. After it was dry I soaked the piece of zinc for twenty-four hours in water, I kept it for three hours in boiling water, and exposed it to the action of a violent rain and snow storm, then razing; I then gave it

some boys to rub it out with a piece of flannel. It proved to be entirely indelible.

1. Preparation of the Ink.—Dissolve one part of blue vitriol (sulphate of copper) in ten parts of rain water, by mixing them in a common vial and shaking them occasionally. One or two drops of sulphuric acid may be added, but this is not absolutely necessary. Use a goose-quill, not a steel pen, for writing.

2. Preparation of the Zinc.—Take thin sheet zinc, and make superficial cuts in it with a broken or shoemaker's knife, against a ruler or a piece of lath or board, to get the cuts straight. By bending the zinc it breaks very easily and smoothly along the cut or scratch. Divide the pieces so obtained into as many labels as you may wish.

The zinc pieces must then be scoured with some fine sand and water. It facilitates the operation if a little salt, vinegar, or muriatic acid is added to the water. Muriatic acid is best in the proportion of one part of it to three parts of water. When bright, put them in rain water, and leave them there till wanted. Rub them dry with a piece of cloth, and write upon them with a quill-pen, as directed. When dry fasten them to the trees. After a few days the names so written will be covered with a white powder; moisten your finger and remove it. The writing will last as long as the zinc itself.—(*American Gardener's Monthly*.)

### WISE FRUIT TREES.

I was talking to-day (April 29) with a Huntingdonshire cottager, and was saying how cold the day had been after our previous hot weather. "Yes," said my friend, "you mus'n't expect the summer to come all at once. The wise tree would have told you better than that. I was up agen the hall this morning, and saw those two wise trees that grow nigh to the fish-stews, and they hadn't put out a mossel o' show." "And what tree may the wise tree be?" I asked. "It's what some folks call the Mulberry," was the reply; "but the wise tree is the name as I've always known it by ever since I was a child." "And why do you call it the wise tree?" "Why, because it isn't silly like some trees as puts out their leaves early, and then gets nipped; but the wise tree, on the contrary, always waits till the frosses has gone right away, and aint to be deceived by a stroke o' fine weather coming early in the season. But when it's sartin sure that it be fine weather and well settled, then it puts out its leaves. O yes, sir, you may rest content on the wise tree telling you when you may be safe against frosses."—(CUTBERT BEDE in *Notes and Queries*.)

[This attribute of the Mulberry is mentioned by Pliny, who says, "Of all cultivated trees, it is the very last to bud, and it does not do so until the cold weather is entirely passed: hence it has been called the wisest of trees." Even the *Heralds* have accepted this, for old Guillim remarks that "this fruit is an hieroglyphic of wisdom, whose property is to do all things in opportune season." The Court-Pendu-Plat Apple is called in some places "The Wise Apple," because it opens its blossoms later than any other variety, and, consequently, they are less liable to be injured by frosts.]

### WORK FOR THE WEEK.

#### KITCHEN GARDEN.

If the present dry weather continue recourse must be had to watering; and this, if not persevered in with a liberal hand, is of very little benefit unless means are used to prevent evaporation. This should be done even with Peas and Beans, and indeed in every case where possible. The vegetables just mentioned will cast nearly all their flowers if water is not supplied; others, such as Cauliflowers, will not attain half the size they should do; while Celery will soon run to seed. All vegetables the roots of which are edible require water frequently, otherwise they become hard and of a disagreeable flavour. Seed-beds to be shaded with mats, which will prevent the necessity of so frequently watering them, and will also be beneficial to the young seedlings in a much greater degree than if left exposed to the sun, even although the roots were moist. Beans, make another sowing, but previous to doing so soak the seed in water, and water

the drills; pinch off the tops of those that are forming their pods. Broccoli, the seed-beds of the late crops to be watered, as also those that have lately been pricked out; none to be permanently planted until after a fall of rain. Cucumbers, the plants will require a good supply of water two or three times a-week during the present hot weather. Sprinkle them every afternoon, which will greatly refresh them. Keep them shaded during the middle of the day. Dwarf Kidney Beans, make a good sowing for the autumn. Water the drills previous to covering them. Peas, sow some of the quick-bearing kinds for autumn use; steep the seeds, and water the drills as for Beans. Continue to stick the advancing crops. Radishes, make a sowing for succession; if the weather continue dry water the ground immediately after sowing, and lay mats on it to prevent evaporation as much as possible. Scarlet Runners, a sowing may yet be made to come in late in the autumn; stick the advancing crops. Turnips, it will be necessary to water the late sowings, and every time after doing so sprinkle them with dust of any kind to prevent the ravages of the fly. Another sowing to be now made. The present season has been an excellent one for destroying weeds, and equally so for ripening their seeds; therefore every one should be eradicated when of small size, as by so doing it will save much future labour. Attend to the thinning of the crops, and keep the soil loose where it is possible to do so.

#### FRUIT GARDEN.

During the present month every attention should be given to trained fruit trees. All wall trees, especially, should be gone over in time, and the shoots thinned and stopped to admit air and light amongst the fruit and young shoots, which will greatly assist in the formation of fruit-buds for the following season. Old Pear trees, in particular, that are unfruitful should be subjected to this treatment. Keep Peach trees free from green fly, and dust sulphur on shoots affected with mildew. Use the garden engine occasionally in warm weather to clean the trees and prevent red spider.

#### FLOWER GARDEN.

Trimming, staking, and pegging down must be well followed up at this period where neatness and order are essential. See that sufficiently strong stakes are applied to plants with heavy foliage and of gross habit, such as Dahlias, Larkspurs, Hollyhocks, Phloxes, and tall-growing Asters. Keep Roses as much as possible free from insects, and if time can be spared, dead blooms should be removed from Rhododendrons. Let Carnations and Picotees be layered as soon as the shoots are in a proper state for that purpose. They make very useful border flowers and are much prized in a cut state. See, therefore, that plenty of them are secured for next season. Propagate China Roses, Pinks, Double Rockets, &c. If Stocks, China Asters, &c., are not already planted out where they are to flower, take advantage of the first shower to do so, and attend to them with water for a few days until they become established. On light dry soils many things will be greatly benefited by a thorough soaking of water, especially coniferous plants, most of which make but one growth during the season, and when rapid growth is wished, they should be encouraged at the proper period. This attention will be especially necessary in the case of young specimens growing on lawns. Ranunculuses, Tulips, Hyacinths, &c., should now be taken up, and after they are dried stored away in some dry room.

#### CONSERVATORY AND GREENHOUSE.

The borders in the conservatory will now require a large supply of water to keep them in a sufficiently moist state, and the soil should be occasionally examined, especially near strong-growing plants, for the amount of moisture absorbed by these at this season is greater than many persons imagine. Whenever water is applied the borders should be thoroughly soaked to the bottom, and where it can be done without annoyance to the family manure water should be given to such plants as are known to enjoy it; this should be furnished in moderate quantities. If red spider make its appearance upon any of the specimens growing in the borders the pot plants in flower should be moved as soon as possible, and the infested subjects given a thorough washing with the engine, and this should be repeated at short intervals until the enemy is thoroughly subdued. Attend frequently to the growth of twiners, and

prevent their getting into a state of entanglement. Cut down Pelargoniums after blooming, and employ the branches for cuttings; the old stools, after a few weeks' rest, may be turned out of their pots, the soil shaken from them, and repotted in smaller pots. By pinching off the bloom-buds of the young Pelargoniums a late bloom may be secured. Perpetual and Bourbon Roses which have been forced should be placed in a cool situation with the view of repressing further activity. After a season of rest the soil should be shaken from them, and all decayed roots removed; after which they should be repotted in fresh rich earth, and removed to the protection of a cold pit and there plunged. As soon as the Camellias, Azaleas, and other plants shall have been placed in summer quarters out of doors, painting and other repairs required by any of the plant-houses should be commenced, as they can be more conveniently done then than at any other season. Pay attention to the plants for autumn and early winter decoration; let them have plenty of pot-room, good rich compost to grow in, a moist atmosphere, and plenty of space for perfect development.

## STOVE.

If among these plants there are any sickly or badly-rooted specimens they should be frequently examined for red spider, otherwise they will become a nursery for this pest, and from them it will soon spread to adjoining plants. See that young growing stock is not allowed to suffer for want of pot room. Attend carefully to watering, giving manure water to all plants in vigorous growth. Gardenias and other things that have been in the conservatory while in bloom, should be replaced in heat as soon as their beauty is over, in order to allow time for ripening their growth before short days and dull weather arrive. Orchids in a growing state will require encouragement. Shading must be promptly attended to when bright sunshine occurs.—W. KEANE.

## DOINGS OF THE LAST WEEK.

WOULD that we could chronicle a fourth of them in these broiling days, with a bright sun, and the thermometer ranging above 80° at midday, and with myriads of things wanting attention, and last year's drought ever coming before us, when we would attempt to give some things a soaking only once a-week, instead of three times as rightly recommended by our friend Mr. Keane. We presume he has the Water-works Company to depend on. What would our old friend think of covering up his pet plants in a wood for a couple of months, as the only chance left him of keeping them alive? Gardening under difficulties is not all a loss, if we are thus induced to make the most of our difficulties. In these days a man must be very little, who can feel over-proud of anything he can do. We shall never forget meeting an old friend with whom, years before, we had lodged in the suburbs of London, as after the first friendly greetings, he exclaimed at a grand horticultural show, "Ah, man! does not this take the conceit out of us?" And no doubt of it. It does not suit many gentlemen to encourage their gardeners to grow for exhibitions, but they certainly stand in their own light if they do not encourage their gardeners to see some of the best of them, as well as some of the best-managed gardens. The garden must be very small indeed, where something may not be learned even by those most advanced in their practice. The greatest pleasure we have had in penning these random notes, is from the proof we have obtained, that the shortcomings and difficulties stated, have been especially appreciated. As a proof of our gratitude, we would wish to state, that all the letters sent with or without names, on the position and the rights of gardeners, and the simplest and best ways of doing work, shall not be forgotten when we get a little more of the bustle over. Just now when mind and body are exhausted before the day's work is over, there is but little time for discussion. We are, however, so sure of the statements made being correct, especially as to gardeners' rights, that we earnestly hope no brother gardener will act in opposition to them. As to the use of tools, if some can manage better with a rake than a hoe, let them use the bridge that carries them over the stream. One friend tells us he could never remove his large weeds without the rake. Our answer would be, Why let them be so large?

## KITCHEN GARDEN.

Much as last week. Have planted little except Celery, and that we shaded. Will allow Cauliflower to remain a little longer. The chief work has been watering Peas, Cauliflowers, &c., and *mulching* them well with short grass and litter as soon as watered. Without the mulching watering did but little good. We have great faith in deep-stirred soil in securing good crops either in wet or dry weather, and more especially if in continued hot weather the surface be roughly mulched. Last season, though for nearly two months Cauliflowers had no water, they were very good indeed, but they were deeply, some 8 inches, mulched with litter, and even that was several times shaken up, so that air should have access to the roots whilst the hot rays of the sun were thrown back from the surface. Lettuces coming in for use were watered and deeply mulched—some were transplanted under shade, but, as stated last week, the best plan is to sow often thinly in rows, and let them stand where sown. They will not run so fast as those transplanted. Gathered a large dish of Broad Beans of the Long-pod kind on the 8th inst., and have had plenty since. This is the earliest period at which we have gathered them here out of doors. They, as well as many other things, will require mulching if this weather last. We have never pleased ourselves with the garden Bean under glass. At one time circumstances made us anxious to have it as early as Peas, but we did not succeed. We had flowers early enough, but they did not set, with the aid of abundance of air, and even of bees to help them. Have any of our readers done much in the way of forcing them? We have fallen back chiefly on the old plan of sowing in boxes and turves, and transplanting out of doors in March.

Run the Dutch hoe through the whole of the kitchen garden where there was room for the hoe to enter; surface-stirring, weed or no weed; and set a careful man to do the same among the Onions, as a careless worker would do more harm with his legs and hoe-handle than he would do good with surface-stirring and cutting up any weeds that might appear. We sowed our Beet this year in the garden and covered with a net, but even now the birds have beaten us, and the plantation will be patchy and need filling up. We shall henceforth make a virtue of necessity and sow in a little bed, and transplant when 3 or 4 inches in height, after which the birds let them alone. Just for trial we sowed also Prince's Feather and Love-lies-bleeding, and run threads over the rows; but we might as well have let the birds have them without let or hindrance. Two or three square feet under protection would give enough of plants for beds or borders. The birds have never interfered with a deep purple Spinach, but the above flowers and the Beet are seized upon as soon as they appear above ground. Is such a fancy among our feathered neighbours at all a common one?

*Cucumber Disease.*—We said a good deal on this subject last season. In a two-light box, which had borne heavily, a slight trace appeared last week, and as we had plenty more the plants were at once taken out, the frame cleared, fresh earth given, and fresh plants turned out. Wherever gum or spot makes its appearance, whatever palliatives may be resorted to, hardly anything will make a cure, and after much experience and inquiry we can say no more on the subject than was stated last season. The best preventives are fresh soil, suitable temperature, and plenty of pure air; and the best remedy is destroying the plants and planting fresh ones.

## FRUIT GARDEN.

A busy time with keeping off interlopers from ripening fruit. Were obliged to run netting over the openings in our orchard-house to keep the larger *birds* from the tempting Cherries. The other morning we counted eighty black-birds and thrushes pecking wherever they could through the meshes of a net over a piece of early Strawberries. Where such numbers abound there is no security except netting, and doing it securely, and keeping the netting considerably above the foliage, otherwise they will sit on the netting and not become entangled in the least. It is when they get under the netting that they become entangled, when scared and they attempt to escape in a hurry. Had they the sense quietly to return to the hole by which they entered they would seldom injure themselves in the attempt to escape. A net merely spread over a place is their delight; they are sure, from the promptings of curiosity, to get below

it to see what there is there. Poor things! at present they must be anxious to find anything to moisten their throats in this parching weather, and did they keep within bounds we would freely let them have their share, but we do not like them having all the produce for which we have toiled.

Watered and mulched the *Strawberries* out of doors. If not covered immediately the watering was but of little use. Could we have spared time we would have set about layering *Strawberry* plants for forcing, and will soon be at them. Seldom have more contradictory accounts appeared than of forced *Strawberries* this season. With the exception of a few of the earliest ours have done well. Many failures, we have no doubt, have taken place from large luxuriant plants and unripened buds. In our description of *Latimers* we especially noted the fine-looking *Strawberry* plants, in large pots, but as they were not wanted early, and great care was taken to ripen the buds, we felt pretty sure that the crop would be better than usual. Hence the hint the other week, to which Mr. Donaldson has kindly replied, and says, "I have President, Admiral Dundas, and Sir Charles Napier, in full bearing, not thinned-out to five or six berries, but to fifteen, sixteen, and even twenty berries each plant. I had President ripe in the larger pots on the 20th of April," and he mentions some mutual friends and others who pronounced them very fine. He also states he had not a blind plant amongst five hundred plants. Those in small pots showed also well, but being placed on the shelves of the vinery did not swell off so well. Mr. Donaldson adds, "I consider the great points are to get your runners early, so as to fill the pots well with roots, and then the crowns are sure to get hard with flower-buds." We would just add as a caution, that those who imitate Mr. Donaldson in using large pots must not satisfy themselves with the half of the plan, but must follow out the bud-ripening process. These splendid plants, when we saw them last season, were each elevated on the reversed bottom of another pot, and standing a good bit apart, so that sun and air might act on pot and roots, as well as foliage. This is a very different thing from placing the pots on the ground, and even in a shady place, and then expecting the plants to be bristling with flower-buds. The appearance of these plants in autumn, and the crops they produced this spring, is just another proof that we must think and plan and work for results.

Other departments much the same as last week, only we managed to finish mulching with rotten dung all the fruit trees in pots in the orchard-house. Scarcely any fire heat has been used for a fortnight, except on one or two cold nights.

#### ORNAMENTAL DEPARTMENT.

Much the same as last week. Owing to the great heat we have allowed a little of our bedding to remain over until there be a change, more especially as other work required doing more, and the plants are all right where they are. For many years we filled a verandah fronted with glass with vases of flowers, and they had a fine effect as a background to a sunk Italian garden. For various reasons, and much against our desire, the practice was discontinued, and now it is to be revived, and we have just been getting them filled. Some of these vases were large and heavy, and not easily moved when full, and some from 5 to 6 feet in height, pedestal and all together. It is not desirable that the floor should be wetted in watering. Previously we had stands made to go below the pedestals to catch the water; but then there was a trouble in moving the vases to get at them. Thanks to a hint from the bricklayer, who was repairing some of the vases with cement, we shall now be able to remove the water without any difficulty. For the larger vases we had pedestals made of deal, from 16 to 20 inches square, and from 4 to 6 inches deep. The top was covered with a board, and a hole cut out some 6 inches in diameter, to let the water trickle down. These we primed and then painted and sanded with yellowish sand, so as to resemble a dark stone. The improvement consists in cutting out on the bevel one of the sides for 10 inches in length, but so hinged that we can place a zinc vessel beneath it 9 inches square, and 2 inches deep, and take it out when it is nearly full, without touching the vase or pedestal. The arrangement is a very simple one, but it will be none the less useful, and the plants can be duly attended to with watering, without ever slopping and sailing the floor. Many other matters must wait until next week.—R. F.

### COVENT GARDEN MARKET.—JUNE 17.

The markets are heavily supplied, and very considerable quantities of soft fruit are coming in from various parts of the kingdom. Great complaints are made of the light crops of *Strawberries* round London. The trade for old *Potatoes* is exceedingly dull.

### TRADE CATALOGUE RECEIVED.

John Foulds, Hullard Hall Lane, Stretford New Road, Manchester.—*Catalogue of Chrysanthemums, Zonale Geraniums, Fuchsias, Verbenas, &c.*

### TO CORRESPONDENTS.

\*\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

SENDING GERANIUM CUTTINGS TO A DISTANCE (J. S.).—We put them into a box in alternate layers with damped moss or damped cocoa-nut refuse, and they should be taken out and planted during the evening of the day they are received.

ROSE LEAVES BLOTCHED (G. C. A.).—Mulch the surface of the soil above the roots of the trees. Water liberally every evening during dry weather. Give liquid manure once a week from your cess-pool, but to each bucketful add two buckets of water.

BOOK (Plato).—The "Cottage Gardeners' Dictionary" contains all that you mention down to the date when it last was revised by Mr. Johnson.

ORNITHOGALUM THYRSOIDES AFTER BLOOMING (Hanley).—If kept under glass gradually withhold water, and keep the soil just moist, but rather inclined to be dry than otherwise until October; then repot, shaking or taking away most of the old soil, and using a compost of sandy loam two-thirds, and the remainder leaf mould and peat in equal parts, with a free admixture of silver sand. We grow the plant in a cold pit, and remove it to the greenhouse for bloom, and when this is over plunge the pot in a sunny part of the garden, and take no further trouble about the plant until it is taken up and potted in October; we then place it in a cold pit. It is hardy with us in a sheltered border and probably so in borders generally, but we have not a sufficient stock to warrant our trying it in this way.

SOAP-BUDS (H. G. Anderson).—So far from injuring they improve the house-ewage for all garden crops. As they consist chiefly of water you need not add so much clear water to the sewage before using it, as is necessary when composed of contributions only from the chambers and water-closets.

**MANAGING HARE'S-FOOT FERN (R. F. R.).**—The Hare's-foot Fern is *Davallia canariensis*. It does very well in a shady part of the greenhouse, and will do fairly in a fern-case if not kept too moist. Plant it in the driest part of your fern-case, or shift it into a larger pot, and so that the thick roots or rhizomes may rest on the soil. Drain well, and use a compost of turfy peat two-thirds and loam one-third, with a free admixture of silver sand. Water freely when growing, and keep the soil moist after the fronds become mature. It usually loses its fronds when the fresh ones begin to appear, or shortly before, and we think your plant was only doing this preparatory to commencing to grow. If you have a greenhouse or a vinery, that would be the best place for it.

**PEACH TREES GUMMING (F. H. Lane).**—Gumming in fruit trees is to be attributed to the sap not being sufficiently elaborated in the leaves, through an excess of food being absorbed by the roots. It is very common to the Peach and Apricot on the Plum stock on dry gravelly soils. Yours is a very bad case. We think the roots are deep in a bad soil, and know of no remedy except taking up the trees and replanting them early next autumn. We had some equally bad, and we took them up, though very old, and with the loss of many branches from gummy exudation, and found the roots had penetrated into the gravel to a depth of 3 feet, and were only bare sticks. The trees were replanted in turfy soil from sods 6 inches thick chopped fine, slates were placed over the bottom of the border at the depth of 20 inches to prevent the roots going down, and the latter were covered with only 6 inches of soil. The trees are now free from gum, and have set too many fruit by ten times. The Apricots are also free from gum, and not making so much wood; and the Peaches, little better than skeletons before lifting, are fast filling with short close-jointed wood. Gum being a disease of the sap, though not communicated from one individual to another, soon spreads to all parts of a tree, just as a disease of the blood in animals spreads over the whole body.

**GARDENING APPAREL (An Amateur Gardener).**—You should wear a substantial pair of boots, and any old habiliments you have whilst you are at work in your garden; but if you wish to be spruce buy a tourist's grey suit.

**CALCEOLARIA SEEDLING (Loch Ness).**—The flowers are good in form and colour, but not unlike many other seedlings which are raised every year. The Rose leaves are extremely fine specimens of healthy and vigorous growth.

**ABUNDANCE OF GRAPES (W. B. d'Almeida).**—The Black Hamburgh under ordinary circumstances would yield you the largest and most unfailing supply. Your other query is answered in "Our Letter Box."

**LILIUM GIGANTEUM AFTER BLOOMING (P. Q.).**—Unless you wish for seeds we would, when the flower-stem turns yellow, cut it off just below the seed-pods. Continue watering as usual for at least three months longer. In September remove to a cold frame in the full sun, and give but little water after this with abundance of air. Protection from frost is all that is required in winter. It may bloom another year if liberal treatment be given when growing, and the bulbs be well ripened off in autumn. Abundant moisture with free drainage when growing, plenty of pot room, and well ripening the bulbs in autumn are the essentials to success. Pot in spring.

**TAKING UP CROCUSES—REMOVING POLYANTHUSES (J.).**—Crocuses are best left in the ground all the year, and only need taking up every three years or so to divide the roots, planting again the same day. They bloom better when not taken up. The Polyanthuses should now have a rather shady and cool border, one shaded from the midday sun, and if they have this with a moist soil they need not be removed, unless the roots are large, when it may be desirable to divide them. Plant on an east border, or where they can have the morning and evening sun with protection from the burning heat of the sun from 10 A.M. to 4 P.M. A little fresh mould placed around the crowns will be of service in preserving the roots from drought, and during very dry weather the plants should be sprinkled with water in the evening—that is, if you do not move them. A little sand placed between the plants up to the crowns is very good at this season. Keep cool and moist.

**EXPPELLING EARTH WORMS (Idem).**—Mix 14 lbs. of fresh lime with forty gallons of water, stir well up, and allow the mixture to stand for forty-eight hours. Water with the clear water during showery weather when the worms are near the surface; they will then come to the surface, and may be cleared away. This repeated a few times will clear the ground. Soot sprinkled on the surface is not liked either by worms or slugs, and is, besides, a good manure.

**PLANTING OUT LILIUM GIGANTEUM (H. W. E.).**—We should not advise you to plant out your *Lilium giganteum* unless yours is a very sheltered place. The soil should be well drained if it is planted out. If you have a spare plant and wish to plant it out, you had better do so at once. Let the bulb be placed about 2 or 3 inches below the surface of the ground. We prefer growing them in the greenhouse, and as soon as they have done flowering put them out in the open air to ripen gradually. They will not require much water, and during their season of rest they are best kept in a cool greenhouse during the winter. We believe that no portion of the patent you mention is sustainable, but we cannot advise on such a subject.

**PHORMIUM TENAX SEEDS NOT VEGETATING (Lex).**—Your seeds seem all right, but we cannot say whether they will germinate or not. They are sown for the most part, though many are defective, and some abortive. The seeds ought to have germinated in one or all of the ways in which they were sown by you. We have sown the seeds repeatedly, and had no trouble in making them germinate. We drain a pot well, and fill to within half an inch of the rim with rather strong loam, and sow the seeds, just covering them with fine soil. The soil is kept constantly moist, and the pot placed in a mild hotbed until the seedlings come up, when they are removed to a cold frame or greenhouse, standing the pot on a cool bottom, or failing that, it is placed on an inverted saucer in the midst of a larger one filled with water, so that the bottom of the pot just touches the water. The young plants are potted off when of sufficient size, and grown on in a cold frame, protected in winter by mats. We should say your seeds are too old to germinate, or they may not have been sufficiently ripened. We have had them from New Zealand, and found steeping them in water at 100° induced germination when they otherwise failed. They were steeped about twelve hours, and sown immediately afterwards, or not allowed to become dry before sowing.

**GERANIUMS IN RICH SOIL (F. C.).**—We think you have added by far too much manure; so much, in fact, that the plants not only refuse to root into it, but those already existing are destroyed. As the leaves flag, and copious waterings only aggravate the evil, your best plan would be to take up the plants, remove the soil, and replant in loam from rotted turves if you have it—if not, in good rather light loam. The rich soil will do very well for top-dressing the beds of *Calceolarias*, *Roses*, &c. Turfy loam with a little leaf mould is most suitable for *Geraniums*. In rich soil they go too much to growth, whilst in that which is very rich they will not grow at all, or only for a brief period, and then go off just when they ought to be growing freely. One-fourth of well-rotted manure is as much as can be given along with loam to *Geraniums* with advantage. More may give vigour, but at the expense of the bloom.

**GNAPHALIUM LANATUM (P. P.).**—*Gnaphalium lanatum* is a very useful plant for edging large beds with, but it is rather too coarse for small beds. It is perfectly hardy. The spring is the best time to divide or propagate it.

**CHERRIES FALLING (Dublin).**—The very heavy crop borne by the trees last year, and the very hot dry weather now prevailing, evidently weakened them. The gangrene or brown ulcers on each Cherry intimate that there is a deficient supply of sap. We should manure the soil for some feet in a circle round each tree, mulch the surface, and water plentifully.

**INARCHING MUSCAT OF ALEXANDRIA ON WHITE TOKAY (D. W. C. N.).**—You should have allowed both rods to grow on till the pruning season had arrived. All that was necessary to be done was to pinch in all the laterals on the stock, so as to throw all the strength you could into the graft. You might have taken a good crop off the old rod without doing the growing cane any injury. We should not advise you to depend on the Tokay as a stock for all your Muscats. We prefer the following kinds for stocks for the Muscats—namely, Black Hamburgh, Trebbiano, and Lady Down's. The reason why the leaves are turning yellow is this, the union was not so complete as you expect, and from cutting the old rod away, the stock has thrown up more sap than the young cane could absorb, and no doubt a large portion has been lost. If the union was not complete the sap would flow to the point where the old rod was cut off, instead of flowing into the young cane.

**INSECTS (V. G. C.).**—Neither of the insects described above is a wire-worm. The first is evidently Snake Millipedes (*Julus pulchellus* or allied species). We cannot determine the longer one without seeing a specimen, but it is probably the Gordian Worm (*Gordius aquaticus*). We know no better remedy than that of placing slices of vegetables in the places they frequent, as they are especially fond of vegetable matter in an incipient state of decay. (*E. Harvey*).—The fact of the Holly buds being attacked by the dirty green larvæ of one of the Tortricidæ or Bell Moths is new to us (those of *Polyommatus Argioles* feed on them). They have now gone into the chrysalis state, and we expect the moths out very shortly.—W.

**VARIOUS (E. A. P.).**—You may remove the tips of the Gooseberry shoots, and thus remove the aphides without injuring the bushes. The treatment of Azaleas after flowering is stated at page 453 of our last Number. The Nile Lily, which we presume is *Nymphaea Lotus*, must be allowed to complete its growth where it is.

**NAMES OF PLANTS (Messine).**—1, *Platyloma flexuosum*; 2 and 3, missing; 4, *Blechnum spicatum*; 5, *Onychium lucidum*; 6 and 7, insufficient; 8, *Cheilanthes hirta*; 9, *Cyrtomium falcatum*; 10, *Adiantum formosum*. *Lez* must send a specimen in flower. (*J. S.*)—*Virgilia lutea*. (*A Donegal Subscriber*).—*Tecoma jasminoides*. (*B. N.*)—*Erysimum obovatum*. We cannot determine the *Calystegia* from the specimen sent. (*G. Grove*).—*Tamarix gallica*. (*T. S.*)—1, *Cherophyllum tremulum*; 2, *Banion flexuosum*; 3, *Galium saxatile*; 4, *Cerastium vulgatum*; 5, *Campanula glomerata* (*A Young Gardener*).—3, *Polemonium conulcun*; 4, *Aubrieta deltoidea*; 5, *Spiraea filipendula*. (*E. D. S.*)—Red flower *Valeriana rubra*, and the other *Cotyledon umbilicus*. The last-named is popularly known as Wall Penny-wort.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending June 17th.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### A METROPOLITAN POULTRY SHOW.

We are rapidly reaching the longest day and as yet we hear no tidings of a poultry show at or near London. Surely the year, and especially this season of it, will not be allowed to slip away without a meeting of the "cock parliament!" What are managers and secretaries about? Will not Mr. Houghton or Mr. Douglas give exhibitors a chance? Why should not the Crystal Palace Show come to life again? Oh! those jolly hours at Sydenham, dear to memory! Do we not recall the pleasant drive through sunny lanes and over breezy uplands, or the not-so-agreeable trips from town, when

"Rattle his bones  
Over the stones,  
It's only a 'cabhorse' which nobody owns!"

rings in the ears of the occupant of the Hansom cab? We remember, too, the palpitating "heart-in-your-mouth" sensation felt as one seeks the well-known quarters of the poultry, and amid discordant crowings of giant Cochins and pigmy Bantams, espies the much-loved familiar pen, and finds it honoured with a coloured card! And then the fun of hearing the comments on your own birds, not always complimentary; and then the cozy luncheon and the best of lobster salads, and the sparkling "cliquot" with which the winner of a "first prize" regales the ladies, and the comfortable spin home in the dogcart, and the mild quiet weed, and last, not least, the delight of your poultry factotum when he learns that "they Brahmas," as he terms them "have won!" Let us hope that the Sydenham authorities will renew such pleasures as these, or, in default thereof, that other scenes may welcome the poultry; that the Agricultural Hall, which seems to rival the Ark in the variety of the animals to which it opens its portals, may again ring with the clarion of the cock; or that Alexandra Park, whose abortive effort last year we all commiserated, may give a chance of "running a tilt" against other exhibitors to—  
BRAHMA POOTRA.

### NORTH HANTS POULTRY SHOW.—JUNE 1.

FOLLOWING the good example of the Bath and West of England Show, the North Hants Society has determined on moving about, and accordingly this year the Show was held at Winchester. We should like another change, to find it extended to other parts of south-western districts—Dorsetshire, Wiltshire might claim a share of the patronage. The different towns might compete in liberality for the presence of the exhibition to the advantage of all concerned. This would make it necessary to prolong the time of showing, and that which is now the affair of a few hours might extend over two or three days. Perhaps, like the creation of Frankenstein, it might assume proportions that would astonish its managers. We should be glad to see it. Dorchester formerly had good shows; Southampton stood well; Salisbury was "to the fore," and now all are in a state of collapse. There is no doubt the south-west could support a large show, and this meeting showed a step in that direction. The stone is rolling. The ground was admirably chosen, close to the town. The inducement of music and an enclosed spot for a promenade, mown and rolled till it was even as a carpet, offered attractions to those (if there be such), who came neither for poultry, sheep, cattle, horses, implements, nor flowers.

The *Dorkings* were most excellent. They would have been a credit to any show in England, for shape, weight, and colour. The first-prize birds were most meritorious; Mr. Fowler's second-prize birds were very good. Several very fine birds in other respects had their spurs growing on the outside of their legs. The *Cochins* gave deserved laurels to Miss J. Milward and Mr. Fowler. The *Game* exhibitors understood their business in matching their birds well. Mr. Bertram's cock and hen were beautiful, and Mr. Dupe's *Duckwings* were deservedly admired. *Polands* are popular in Hants, but it is hard to beat Mrs. Pettat and Mr. T. P.

Edwards. The *Spanish* were better than we have ever before seen at this Show, and Mr. Simmond's birds, if shown in good condition, will repeat their exploit. We have not of late seen a better pen of Golden-pencilled *Hamburghs* than those shown by Mr. Pettis, while the quality of the Spangled may be judged from the fact, that Mrs. Pettat took only second prize. *Brahmas* are decidedly becoming popular, and here as elsewhere, there were two classes, one for light, and one for dark. Mr. Pares took both in the first. In the second, great names met. Mr. Boyle, of Dublin, was first; Mr. Fowler second; and Mr. Hinton was highly commended. The *Various* class deserves more than two prizes. *Andalusians*, *Malays*, *Crève Cœurs*, *Black Hamburghs*, *Pheasant Malays*, and *Bantams* form a large class. Mrs. Pettat was first with *Sebright Bantams*; Mr. Hinton, second, with *Malays*. Many of the commended deserved more.

Mr. Fowler made a clean sweep of the *Duck* prizes. His prize birds were 7½ lbs. each.

There was a small show of *Rabbits*. The longest ears measured 20½ inches. In the foreign class the prize went to a large Rabbit accurately marked like a Himalayan and covered with long silky hair. That for all points went to a remarkably handsome one weighing 9½ lbs., and measuring 19 inches.

This Show becomes every year more successful, owing partly, no doubt, to the excellent management and constant attention of Mr. Downes, the Secretary.

In addition to the prizes awarded, which will be found in our Number for June 6th, the following commendations were given:—

**DORKING.**—Highly Commended, G. Johnson, Farnham, Surrey; C. Smith, Durnford, Salisbury; Mrs. Pettat, Ashe, Micheldever; T. P. Edwards, Lyndhurst.

**GAME.**—Highly Commended O. Nicholson, Fareham.

**POLAND.**—Commended, Mrs. Pettat, Ashe, Micheldever.  
**SPANISH.**—Commended, W. Newman, Walsall; Rev. J. De L. Simmonds, Chilcomb Rectory, Winchester.

**BRAHMA POOTRA.**—Highly Commended, J. Hinton, Hinton, Bath.  
**ANY OTHER VARIETY.**—Highly Commended, J. Pares, Childown Hall; Chertsey; Rev. S. Terry, Dummer; Mrs. Pettat, Ashe, Micheldever. Commended, Mrs. Bennett, Chilmark, Salisbury.

**DUCKS.**—Highly Commended J. W. Kellaway, Merston; E. Curtis, Dummer. Commended, Mas Silence, New Barn, Compton.

**RABBITS.**—*Variety* (to include all points).—Highly Commended, J. H. Robinson, Winchester.

Mr. Baily was the Judge.

### THORNE POULTRY EXHIBITION.

(From a Correspondent.)

THIS Society has now been established thirteen years in connection with an agricultural show. Each year, we are happy to say, its success has proved regularly progressive, but certainly the advance this year has been more apparent than ever.

The Show took place on the 14th inst., in the beautiful grounds of Makin Durham, Esq.

Of the *Spanish*, with the exception of the winning birds, we can say but little, as the condition in which the generality of the birds in this class were shown was inferior. *Cochins*, shown by Messrs. Wood and Beldon, were very good, and we also noticed a nice pen of *Silver Cinnamons*. *Dorkings* were poor. *Game*, *White* and *Piles*, the prize birds were good, also the pens of *Black Reds* shown by Messrs. Brierley and Snowden; the *Duckwing* class was a very poor one. The prize for a *Game* cock and one hen was closely competed for by Messrs. Chaloner and Aykroyd. Both pens were really good, and the former took the silver cup, value £5. The *Single Game* cock class contained many good birds. Mr. E. Aykroyd won the cup with a splendid *Brown Red*. The show of *Hamburghs* was good, the birds of Messrs. Beldon, Burch, and Butler were far a-head of the rest. The next class of note must receive the greater praise. The class for *Game Bantams* was, without exception, one of the best in the Show, and the birds of Messrs. Crosland and Brierley were splendid and shown in prime condition. The Judges awarded the silver cup to the former pen on account of their smallness; and we were given to understand, that the second and third prize pens had won similar events for the present cup winner. In *Bantams*, *Gold* and *Silver-faced*, and *Black* and *Whites*, the prize pens were very nice.

There was a very good show of *Pigeons*, and we are glad

to inform exhibitors that the Judges' awards gave general satisfaction.

**SPANISH.**—First and Highly Commended, H. Beldon, Bingley. Second, E. Brown, Sheffield.

**COCHIN-CHINA.**—First, R. J. Wood, Chorley. Second, H. Beldon, Bingley.

**DOCKING.**—First, W. Charter, Sheffield. Second, Hon. F. C. H. Hawke, Womersley Park. Commended, J. Sledmore, Epworth.

**GAME (White and Pile).**—First, J. Sunderland, Coley Hall. Second, R. Dodge, Sheffield. Commended, J. Hodgkinson, Hull.

**GAME (Black-breasted and other Reds).**—First, C. W. Brierley, Middleton. Second, H. Snowden, Great Horton. Commended, J. Sunderland.

**GAME (Duckwing and other Greys and Blues).**—First, H. Snowden, Great Horton. Second, E. Aykroyd, Bradford. Highly Commended, Messrs. Sales and Bentley, Crowle. Commended, G. Cocking, jan., Crowle.

**GAME (Any variety).**—First and Cup, C. Chaloner, Steeley. Second, E. Aykroyd, Bradford. Third, J. Sunderland, Coley Hall. Highly Commended, H. M. Julian, Hull; W. Boyes, Beverley. Commended, J. Fletcher, Manchester.

**GAME COCK (Any variety).**—First and Cup, E. Aykroyd, Bradford. Second, J. Sunderland, Coley Hall. Highly Commended, W. Boyes, Beverley (Red); J. Fletcher. Commended, H. M. Julian, Hull (Red); C. Chaloner, Steeley; G. Helliwell, Walkley.

**POLAND (Any variety).**—First, C. W. Brierley, Middleton. Second, H. Beldon, Bingley.

**HAMBURGHS (Silver-spangled).**—First and Second, H. Beldon, Bingley. Highly Commended, A. K. Wood, Burnside, Kendal.

**HAMBURGHS (Golden-spangled).**—First and Second, Messrs. Birch and Boulter, Sheffield. Commended, H. Beldon, Bingley.

**HAMBURGHS (Silver-pencilled).**—First, H. Beldon, Bingley. Second, G. Helliwell, Walkley. Highly Commended, J. Hepworth, Bearswood Green.

**HAMBURGHS (Golden-pencilled).**—First and Second, Messrs. Froggatt and Harrop, Walkley. Highly Commended, W. Charter, Sheffield.

**ANY FARMYARD CROSS.**—First, H. Beldon, Bingley. Second, C. W. Brierley, Middleton.

**GAME BANTAMS (Any variety).**—First, Master C. Crossland, Wakefield. Second and Third, C. W. Brierley, Middleton.

**BANTAMS (Silver or Golden-laced).**—First, C. W. Brierley, Middleton. Second, Messrs. S. & R. Ashton, Roe Cross. Highly Commended, H. Beldon, Bingley.

**BANTAMS (Any colour).**—First, C. W. Brierley, Middleton (White). Second, J. R. Jessop, Hull (White).

**BEST COCK (Any Breed or Cross).**—First, H. Beldon, Bingley. Second and Highly Commended, Messrs. Birch & Boulter, Sheffield (Spanish). Commended, H. Merkin, Driffield (Cochin). *Hens.*—First, Messrs. Birch and Boulter (Spanish). Second, H. Beldon. Commended, S. Taylor, Cantley; R. White, Sheffield (Cochin).

**BEST COCKEREL AND TWO PULLETS (Any pure breed).**—First, G. Helliwell, Walkley. Second, H. Snowden, Great Horton.

**EXTRA STOCK.**—Prize, J. Hawley, Doncaster (Crève Cœur).

**GUINEA FOWLS.**—First, Hon. F. C. H. Hawke, Womersley Park. Second, H. Merkin, Driffield.

**TURKEYS.**—First, C. W. Brierley, Middleton. Second, Miss Smith, Hatfield.

**GESE.**—First, O. A. Young, Driffield. Second, Mrs. Lee, Thorne.

**GIBS.**—First, Hon. F. C. H. Hawke. Second and Commended, Mrs. Langhorn, Arny.

**DUCKS (Any variety).**—First, H. Beldon, Bingley (Rouen). Second, J. R. Jessop, Hull.

**PIGEONS.—Carriers.**—First, W. Massey, York. Second, H. Yardley, Birmingham. Highly Commended, E. E. M. Royds, Ashby-de-la-Zouch. Commended, H. Snowden, Great Horton; E. Brown, Sheffield.

**Croppers.**—First, E. Brown. Second, H. Snowden. Highly Commended, H. Yardley. Commended, E. E. M. Royds.

**Tumblers.**—First, E. Brown. Second, W. Massey. Highly Commended, Messrs. R. & C. Gravill, Thorne. Commended, H. Yardley.

**Jacobins.**—First, H. Yardley. Second, R. Favell, Sheffield. Highly Commended, T. C. Taylor, Middlesborough.

**Nuns.**—First, C. Addey, Epworth. Second, J. Pickering, Driffield.

**Trumpeters.**—First, A. Middleton, Newport. Second, E. E. M. Royds.

**Turbits.**—First, E. Brown. Second, H. Yardley.

**Fantails.**—First, T. C. Taylor. Second, H. Yardley.

**Owls.**—First, H. Yardley. Second, E. E. M. Royds.

**Barbs.**—First, E. Brown. Second, H. Yardley.

**Extra Stock.**—Prize, C. Addey.

**JUDGES.**—William Smith, Esq., Beech Hill, Halifax, and Thos. Dodds, Esq., Warren Cottage, Wakefield.

**FRANCIS RICHARD PEASE, Esq.,** of Southend, Darlington, died on the 7th inst. at the early age of twenty. As a poultry fancier and exhibitor nothing can so clearly bear testimony to his practical earnestness and soundness of judgment in this fancy as his numerous triumphs at so many of our poultry shows, where his fine birds must in the future be missed. But Darlington will especially suffer from his absence, as this Show owed to his quiet unobtrusive, yet masterly and liberal efforts to make it deserving the district, more than is generally known. His labours in this at so early an age and with so weak a state of health were great promises, had life been spared him, of an amount of public usefulness, the loss of which must be generally regretted.—W. W.

**CROOK'S INCUBATOR.**—On the evening of the 9th inst., Messrs. Crook, of Carnaby Street, exhibited their artificial incubator and artificial rearing apparatus, at the Royal Institution, Albemarle Street. It was arranged so as to show it in action with their new gas lamp, and the chicks coming

out; others under the artificial mother; and some feeding in portable runs. The sound of the young ones chipping inside the eggs was a novelty to many of the audience.

**BEE-KEEPING IN DEVON.—No. XXIII.**

**A COUPLE OF MISTAKES AND THEIR CONSEQUENCES.**

YESTERDAY (June 14th) I took a trip a few miles into the country with the view of inspecting the apiary of a clerical friend, who within the last few years has become rather an enthusiastic bee-keeper, and who, having advanced so far as to adopt Woodbury hives, had recently attempted to follow the instructions given in page 407 of "Our Journal" (of which, I need scarcely add, he is a constant reader) by forming a small artificial swarm or "nucleus."

I learned that he commenced proceedings on the 27th of last month by taking a brood-comb from a strong stock, and placing it in a nucleus-box between a couple of spare combs, and with a small population abstracted from the parent hive. Having scrutinised the brood-comb most rigidly he said to himself, "It's all very well for Mr. Woodbury to talk about seeing the queen on another comb, but I'm quite sure she's not on this one, and, besides, I really fancy I did catch a glimpse of her on another." So the nucleus was put in its place and left for four days, when it was examined with the view of ascertaining how many royal cells had been started. Somewhat to my friend's surprise he found that not even one had been commenced. Rather puzzling, this! but never mind, we'll give them another brood-comb, and then all will doubtless go well. Another comb was accordingly abstracted from the unfortunate parent stock, and the nucleus left quiet for a few days longer, when, an apianian friend happening to call, the box was again overhauled, and, instead of the expected royal cells, there was the old queen composedly traversing the first comb that was lifted out. What was now to be done? A council of war was hastily held, and it was ultimately decided to let things remain as they were—the old queen in the nucleus-box, and the bees in the parent hive raising royal cells to supply her place. Subsequently another nucleus was formed by extracting a comb with a royal cell and some bees from the old stock.

The parent hive and two small artificial swarms were submitted to my inspection, and I took them in the following order:—First the nucleus (now transferred to a full-sized hive) containing the old queen. Here I found brood had been added too fast, so that in every comb much had become chilled, and appeared in various stages of decomposition, interspersed with healthy brood, but remaining, as yet, unremoved by the bees. At my especial request my friend kindly consented to permit matters to continue in the same state, with the view of ascertaining whether the bees as they increased in strength would be able to remedy the evil, or whether there was any foundation for Mr. Lowe's opinion that under such circumstances foul brood must follow as a necessary consequence.

Next came the parent hive, now supposed, and no doubt correctly, to possess a young queen; but here the bees turned out so vicious that I had to put on gloves (a most unusual circumstance), and we were glad to be content with a partial examination. The two first full-sized combs were solid masses of sealed honey, so we made prize of the first and substituted an empty one. On the third comb we found the remains of two royal cells—one opened naturally, and from which a young princess had evidently emerged, the other torn open at the side, and marking the untimely destruction of its hapless inmate by her elder sister. This discovery leaving, as it did, no reasonable doubt of the existence of a young queen, sufficiently contented us, and we replaced the crown-board, glad to have done with such a cantankerous lot, whose vindictive and persevering attacks contrasted most unfavourably with the demeanour of my own mild and placable Ligurians.

In the second nucleus appeared a naturally-opened royal cell, and we presently espied its late tenant briskly traversing the same comb, and evidently in a high state of activity and health.

Having finished our examination my friend declared himself exceedingly well pleased with the result. His mistake had cost him, he said, a good super of honey, which he would

doubtless have obtained from the old stock had it continued in possession of its original queen; but, on the other hand, he considered he had gained far more than its value from the experience it had afforded him; actual experience being, as he justly remarked, of far more practical value than anything that could be learnt from books.

Passing the other colonies, some swarms, some old stocks, and some working handsome supers, but all in a most flourishing condition, my friend paused before a flat-topped straw-hive. "Here," said he, "I fear I have made another mistake," and proceeded to explain that a swarm having settled in two clusters he had hived them in different hives, which were left on the ground side by side until the evening, when finding that both hives continued tenanted, he concluded that each possessed a queen, and placed them on their respective stands, but now feared that the one before which we stood was in reality queenless. On turning it up I saw a small cluster of bees and three or four new pieces of comb, but immediately and confidently pronounced my friend's suspicions to be correct, for of these new constructions all were drone-combs. "What is to be done with them?" was the next question. "Give them to me," was my reply, "and if I am lucky in queen-rearing you shall have them back again with a Ligurian queen at their head." And so I took my place in the railway carriage on my way home, putting the hive of queenless bees under the opposite seat, which was forthwith occupied by a clerical gentleman, who on finding the kind of company he was in, smilingly requested to be informed if the railway bye-laws did not prohibit the conveyance of lucifer matches, bees, gunpowder, and other explosive combustibles? declaring that for his part he would rather be seated on a cask of gunpowder, since it was scarcely possible that that would explode, whilst he deemed it highly probable that the bees might escape! Our safe arrival at the Exeter station, however, speedily relieved him of his jocularly-expressed fears, and of the company of the bees as well as that of—A DEVONSHIRE BEE-KEEPER.

#### PUTTING TWO SWARMS INTO A STEWARTON HIVE.

Will you kindly inform me whether if I put a swarm of bees in the lower box of a Stewarton hive and a second in the box immediately above it, the two could be made to unite and so form an extra strong stock?—G. H. H.

[If the two swarms issue within a few days of each other and are united immediately, we do not think there would be much risk of a quarrel.]

#### SWARMING VERSUS STORIFYING.

In my communication under the signature of "AMATEUR," at page 277, detailing my success with the storifying as compared with the swarming system, I promised to record my further progress.

Acting on my resolution, I procured from the country a couple of stocks of bees in common straw skeps to people the boxes of my two new octagon covers, and after these had remained sufficiently long to become familiarised with their new locality, I had them driven on May 9th, and their combs transferred to the frames of my new Stewarton boxes. This last operation was accomplished in a most expert and satisfactory manner in the genial warmth of the greenhouse, thanks to the considerate kindness of my friend, "A RENFREWESHIRE BEE-KEEPER," in again sending his man to aid me in the work.

After the two new octagon frame boxes had been completed, we had as much brood comb left over as filled the frames of a third octagon-box, with which I resolved to nadir my old strong colony. On attempting to raise the pile of three boxes out of the cover, the weight was so great that I first lightened it of the topmost breeding-box, and was taken by surprise to find its every cell filled with fine honey, as it doubtless had been left at the end of the season. It weighed 30 lbs. gross; deducting 4 lbs. for the box leaves 26 lbs. nett; this added to the 68 lbs. formerly reported at page 278, gives a total honey harvest of 94 lbs. from the one hive. Last season, the remaining two boxes were still so weighty as to quite justify the preliminary spoliation process

by the removal of end combs, &c.; but the season I considered not sufficiently advanced, and resolved to content myself meantime with what I had taken.

Such a yield of honey from one stock, in a town locality, too, impresses me most favourably with the storifying system, and the skilled manipulation of Stewarton hives in effecting results I could hardly have supposed possible from my experience of the old swarming plan.—R. B.

#### BEEES IN AUSTRALIA.

WE copy the following from *The Australasian* of March 4th:—Woodbury frame-hives were first introduced into the colony with the Ligurians, and appear to have been fully appreciated, whilst we have reason to know that the "Victoria Apiarian Society" numbers among its members many accomplished bee-keepers. The innocence of the Melbourne editor's reply is, however, perfectly refreshing; he is evidently in a state of the most blissful ignorance alike on the subject of drone-breeding queens, fertile workers, or parthenogenesis in the honey-bee:—"I took a notion of keeping bees, and commenced six weeks since by placing a swarm in one of Woodbury's frame-hives. I thought I had a splendid hive, but on closer examination I found the brood were all drones!

"As I understand the drones never collect any honey, and are only useful for breeding and keeping the brood warm, I am inclined to think that my hive will become extinct. I would feel very much obliged if you would advise me how to cure them.—J. G."

[Your communication is very remarkable. How did you come to buy a hive of all drones? It is the oddest transaction in the apiarian line that we ever heard of. As to curing a hive of being drones, *alias* males, you might as well attempt to cure men of being men, or women of being women.—Editor of "The Australasian."]

#### OUR LETTER BOX.

GEESSE AT THE BRENTWOOD SHOW.—Mr. Postans of Brentwood, Essex, informs us that the Geese which took first prize on the 6th inst. belonged to Mr. Postans of Shelley, in Suffolk.

MANAGEMENT OF BROODY HENS.—HENS PECKING THEIR EGGS (G. H.).—We can see nothing wrong in your management. It has not been a good hatching year because we, like yourselves, have had clear sittings. We had on one day three out of four. Such a thing has never happened before. All our hens sit on the ground, but they are all confined, and in semi-darkness. We would kill any hen that ate the eggs she sat upon. We can only suggest one thing, and that is, that the hens should have dust at hand when they come off to feed. It is the sovereign remedy against vermin, and under the influence of the irritation caused by these parasites hens can not only not sit well, but they will do all sorts of strange things.

EARLOBES OF LA FLÛCHE COCK (E. P. L.).—The earlobes should be quite white. It would be a disadvantage in exhibiting, and in close competition would certainly turn the scale against him.

FOOD FOR YOUNG PARTRIDGES (W. B. d'Almeida).—Young Partridges should be fed on chopped egg, bruised wheat, bread-crumbs, and curd. They must always have water. If the hen with the young is put near a grass or clover field, they will run therein, and find much of their food; but this is only a help. The hen should not be allowed to leave the run, and it should be secured from vermin at night. Cats are great destroyers of young Partridges. Magots of any kind are very serviceable to young Partridges, but especially the larvae, or "eggs," as they are usually called, of the ant. In June and July they prefer these to any other food. We have no recollection of your inquiry about a cow shed.

We have again deferred the answer to the "COUNTRY PARSON" because we are in daily expectation of being able to give him more information than he asks.

FERTILE WORKERS (W. Carr).—Having observed this phenomenon in our own apiary, we have no doubt whatever of its occasional but very rare occurrence.

BUFF AND BLACK-SPANCOLED PIGEONS (A Subscriber).—Your Pigeons are evidently one of the varieties of Le Pigeon Maille; probably the walnut-coloured variety, known here variously as Porcelain, Hyacinth, Victorias, and by other names.—E. P. B.

HIVES (Ferdinand).—For five postage stamps you can have from our office, free by post, if you send your direction, "Bee-keeping for the Many." It contains drawings and a description of the Woodbury hive, Marriot's and Neighbour's hives are much the same. The former, we believe, cannot now be purchased.

SAFEST TIME FOR PUTTING ON A SUPER (A Would-be Bee-Master).—The middle of a fine day is the best time to put on a super as well as for watching the proceedings of bees and performing most other operations on them. When honey is plentiful, their attention is so concentrated on the one grand object of collecting and storing it, that they take but comparatively little notice of the operator or spectator. Towards evening, when the day's work draws near its close and most of the foragers have returned home, they are far more on the alert, and their suspicions are so readily excited that, as in your own case, stings are frequently inflicted with little or no apparent provocation.

SILK-WORMS' SILK.—A lady wishes to know how to dispose of the silk, and whether it should be wound off or left on the cocoons.—C. W. P.

From observations taken near London during the last thirty-eight years, the average day temperature of the week is 72.9°, and its night temperature 49.8°. The greatest heat was 91° on the 30th, 1862; and the lowest cold, 34°, on the 30th, 1863. The greatest fall of rain was 1.18 inch.

MANURING THE AIR.

MANURED atmospheres may seem at variance with the requirements of a plant and contrary to the common course of Nature, but it would be no difficult task to prove that manured atmospheres are within the order of Nature herself. I shall not, however, attempt to do this, but I take for granted that plants feed at night by their leaves, or absorb from the atmosphere nourishment nearly, if not quite,

equal in amount to that derived from the soil. There is not a gardener but will agree that a hotbed of leaves, dung, or other fermenting materials is more suitable for the growth of plants than any other description of artificial atmosphere. It was a common practice to place fermenting dung in vineries on commencing to force, and it was usual to start nearly everything by the aid of dung hotbeds. Whether knowing or not knowing that the steam of fermenting dung was highly conducive to vegetable growth, our fathers in horticulture employed it as largely as we do little. It might not be known to them that the steam generated by the fermentation of the dung parted with its ammonia, and fed the plants by the foliage; and I believe that they were perfectly ignorant of the value of the vapour of hot dung as a manurial agent, and only valued it as maintaining a moist and more uniform heat than flues. At the present day the whole system of heating has undergone so great a change by the introduction of hot water in iron pipes, that dung hotbeds are but little used in comparison to what they were. In the good old times syringes were but little employed, they came in with the present system of heating, and were necessary to counteract the evils of a dry heat; and supplying moisture by sprinkling the floors and syringing the foliage was no doubt prompted by the knowledge that a moist heat was necessary. Accordingly, these proceedings were intended as an equivalent for the steam of fermenting materials. These means, however, were not sufficient, and tanks and guttered pipes were soon invented to more regularly maintain a moist atmosphere, and with the same object flue-covers were made hollow to hold water; yet, after all, an equivalent for the moist atmosphere of hot dung was not secured. It was not simply moisture that it was necessary to supply, but the ammonia of the dung as well: hence we find soot water used by Mr. Fish, and of late guano water by Mr. Thomson, of Archerfield. It must be evident that soot and guano possess little evaporative except ammonia,

and this is precisely what the atmosphere of a house heated by fermenting materials contained along with watery vapour.

I need not search for further evidence in support of ammonia, as vapour, being a manurial agent absorbed by the leaves. Its utility as an invigorator of growth and insect-destroyer is undoubted. If there is an insect that may be attributed to a deficiency of moisture in the atmosphere it is red spider; its presence is ever a sign of a vitiated parched atmosphere, not necessarily dry but lacking the vapour of water fresh from the clouds, which is equally destructive to this pest with soot water. Ammonia few insects can well endure, and, unlike other remedies, it contributes to the health of the subject. It might be argued that red spider does not attack vigorous plants in the same atmosphere. I am not quite certain that plants do not throw off through the leaves any excess of nutrition absorbed by their roots, and this may be retained within the house through early closing, and absorbed by the leaves again at night, and plants would thus be fed, as they naturally are, by the dew at night.

I do not think it will be doubted that fresh rain water is more conducive to growth than that a month old from a tank, or if it be questioned it would be well to account for artificial waterings never being so beneficial as natural ones. If it were possible to have houses so constructed that they could be opened to admit of the rain falling on the plants or fruit trees, I am firmly persuaded it would do more good than many artificial applications.

Setting aside many considerations, we find that some manures are richer in ammonia than others—soot contains a considerable amount, and more especially Peruvian guano and sheep's-dung. These are the most powerful, and scarcely less so are the drainings of a dunghill when they consist of the washings of horse-droppings. My experience is limited to the liquid manures made from these substances. They are made in a tub or barrel holding twenty three-gallon-watering-potsfull of water, or 60 gallons; a peck of fresh sheep's-dung, the same of soot, half a bushel of horse-droppings (fresh), and 15 ozs. of guano are put in each respectively, and soft water poured on them, and well stirred up. In this state the liquid is poured into the evaporating-troughs, and used for sprinkling the floors, &c., of the houses, but is not applied to any highly-heated surface, such as a flue or hot-water pipe from which it would be quickly evaporated. For syringing the clear liquid only is employed, and always at the time of shutting up the house or a little afterwards. In whatever form it is applied, whether in evaporating-pans, sprinkled on the floors, or syringed on the plants, the atmosphere is sensibly impregnated with ammonia, and the odour is not unpleasant, except in the case of soot water, the vapour from which retains the sooty smell. The drainings of the dunghill diluted with an equal volume of water, used in evaporating-pans and for sprinkling the floors, &c., are the most objectionable on account of the smell, though those not actually aware of this liquid being used would not feel annoyed. For syringing with, it is diluted with six times

its volume of water, and always in the afternoon when the sun has lost much of its power. I must remark that the drainings used for this purpose contain no urinary matter except that derived from the solid manure.

All these liquids are used of the same temperature as that of the house, the liquid being heated and strained through a muslin or tiffany bag, so that dirt may not get into the syringe. Some discrimination is necessary in using the manure water for syringing purposes. When the leaves of Vines are young, and consequently tender, it should be diluted one-third more, and the same for Melons, Cucumbers, and all plants of which the leaves are young and soon scorched. After they attain their full size it may be given at the strength named, but always with the declining sun. The clear liquid only is used for syringing with.

I have used all the liquids named at four times the strength stated above for filling evaporating-troughs, but only for destroying insects; for I find that the ammoniacal vapour when very strong is apt to scorch the leaves, particularly when the air becomes saturated with it and the sun is powerful. I may also state that when the evaporating-troughs are filled to overflowing, and the liquid drips on the hot pipes or flues, the air is so quickly filled with the vapour that the leaves of Vines and similar plants, especially when young, are scorched. When, however, the leaves have arrived at that stage at which red spider usually attacks them there is no danger in using the liquid at four times the strength, and as charging the atmosphere with ammoniacal vapour is necessary to destroy mealy bug and red spider, that strength becomes a matter of necessity, otherwise only weak doses are needed as invigorators, whilst syringing the foliage renders it very distasteful to insects.

Ammoniacal vapour, though desirable, should be used with care. Smooth or plain-leaved plants, as Vines, Figs, Peaches, Plums, Cherries, Pines, Gardenias, Oranges, and all those usually attacked by red spider, will endure vapour of double the strength I have stated, and may safely be syringed with the liquid after the leaves attain their full size; woolly and soft-textured leaves, as those of Gloxinias, Azaleas (though not soft but hairy), Gesneras, and Pelargoniums, had better not be syringed, and should never be exposed to a highly ammoniacal atmosphere.

Finally, I would state my conviction of the little reliance to be placed on ammonia alone, thinking it best applied along with phosphates. I find the different salts of ammonia vary so much in strength as to make their use unsafe. The best that I have used was a solution of ammonia made by dissolving 1 lb. of carbonate of ammonia in a gallon of water, keeping the solution in a close-stoppered bottle, and putting a little in the evaporating-pans at the time of shutting up the house. A pint was allowed for a house 30 by 18 feet, 5 feet high at the sides, and 12 feet from the centre to the apex. I must admit that this sensibly invigorated the foliage of the plants, it being larger, and the roots of Orchids were more plentifully emitted, but there was not that increased greenness in the leaves which is the characteristic of an atmosphere manured with guano or sheep's dung in solution. In fact, the foliage was not of so good a colour as without the ammoniacal vapour. We gave it up and converted the carbonate into the sulphate of ammonia by dropping sulphuric acid into the solution till all bubbling ceased. For stimulating the growth of plants, sulphate of ammonia at the rate of 1 oz. to eight gallons of water, is, perhaps, unequalled, it being applied the same as other liquid manures to plants in a growing state.

After giving it may not be out of place to ask for information. Has the presence of ammonia been detected in atmospheric air by analysis? Liebig says nay, and yet he notes its presence in rain water and snow. There is every reason to believe that it does exist in the atmosphere, and descends with the dew and the rain; \* but if it be traceable in water,

\* That falling at Rothamsted, in Hertfordshire, twenty miles from London, has been examined by Professor Way. He found (grains) in an imperial gallon in—

	Ammonia.	Nitric acid.		Ammonia.	Nitric acid.

—(Science and Practice of Gardening, page 74.)

why not in air prior to rain, when the air is often nearly saturated with moisture? Fact proves the presence of it or some other powerful stimulant descending at night with the dew, and exciting plants into growth days even before actual rain falls, and if it come a shower without wetting the earth beyond the surface, what an alteration it makes in the face of nature. The drooping leaves revive, the buds burst their scales, flower-buds swell and await the first gleam of sunshine to unfold their beauties. Then rain water from an open tank some days after falling, is less invigorating than fresh, winter rain water less marked in its effects on vegetation than that which falls in spring and summer. Snow water is the softest of water, it contains ammonia.—G. ABBEY.

### VARIATION OF COLOUR IN HYDRANGEA FLOWERS.

I HAVE read with much interest Mr. Robson's article on the Hydrangea, but I am sorry it does not go further towards solving the mystery as to the cause of the flowers being occasionally blue; and I hope the discussion he has invited may give us a little more light on the subject, but I am not very sanguine on that point, as I think that if blue flowers could be produced at will some of our great Covent Garden florists would have made a display of such before this. The blue-flowered Hydrangea has been a great mystery to me from a boy. I have seen a plant produce blue flowers one year and pink the next, or, perhaps, a year or two pink, then blue, and so on; but I never saw a very young plant with blue flowers. What seems more curious than all was one large plant I knew that used to produce blue flowers on one side and pink on the other—the most shaded side produced the blue flowers. Has Mr. Robson ever seen or heard of such an occurrence before?

It is not at all uncommon to see the Hydrangea with blue flowers in the neighbourhood of which I am writing—namely, on the borders of the Forest of Dean, in Gloucestershire, where I have seen some plants with pink, others, perhaps in the same bed or border, with blue flowers, and to all appearance in precisely the same sort of soil, which was a heavy loam, resting on a sort of red sandstone, where the Foxglove was quite at home; and so far agreeing with what Mr. Robson says of the Rhododendron.

The Hydrangea used to be cultivated much more in that part of England than in the others to which I have been since leaving there—I mean as an out-door plant. Mr. Robson says it is quite hardy, but I am not quite sure of this; for I have seen it killed in several places in the winter, but in some only killed down to the ground, yet rendered useless as a flowering plant. Here, and at a place in Kent (near Ashford), I have found they will not stand the winter—at least not their shoots.—J. BRYAN, *Heydon House, Royston.*

[Some years since the late Mr. Beaton wrote to us upon this subject, as follows:—

“There is one disadvantage in August-made cuttings of the Hydrangea, which is, that the flowers of them come all of one colour, and that the same as that of the parent plant, whether it be blue or pink; but those made in February may be made to flower blue or pink at will. If the mother plant produced blue flowers in the former seasons, and you force it in February, cut off your cuttings as soon as they make three joints, and when they are rooted place them in a rich, light compost, say one-half leaf-mould or very rotten dung, and the rest of any good garden soil, they never fail to produce pink flowers; whereas, if taken from a pink-flowering parent, and after rooting growing them in strong yellow loam, with about a sixth part of iron filings mixed with it instead of sand, nine out of ten of them will produce blue flowers. I have proved this over and over again, and have seen it in other hands, but I never could get an August cutting to differ in colour from that of the parent plant. The reason seems to be that the juices of the parent plant have already, by a season's growth, formed the substance, or the organised matter, as physiologists call it, out of which flowers are produced, so that no after-treatment is able to counteract the effect; whereas if cuttings are separated from a plant at so early an age as when they only attain a few inches in length, and are then made to grow in iron rust

and loam otherwise impregnated with iron, which is well known to favour the production of blue flowers in the Hydrangea, the organised matter referred to is formed from juices impregnated with iron oxide, and so produces blue flowers. The intensity of the blue is, I believe, according to the perfect oxidation of the iron. Chalk water never fails to counteract this effect of the oxide on the flower, as we have often proved here, so that, to give the fairest chance to the experiment of getting blue Hydrangeas, I would recommend the cuttings to be taken as early in the spring as possible, to strike or root them in red sand, to grow them in nothing but red loam and iron filings, according to the above proportions, and never to water them but with rain-water: but I am not sure whether rusty water from hot-water pipes would not add to the success of the experiment; at any rate this rusty water is not injurious to these Hydrangeas. In some parts of the country the natural soil will produce blue Hydrangeas, and in such places it is difficult to meet with pink ones; and, what is singular enough, the Rhododendrons will flourish in such soil, although apparently devoid of all traces of vegetable matter. There is also a kind of peat earth which invariably turns the pink to a blue Hydrangea, but all the peat that we have access to here (Suffolk), does just the contrary. To have pink Hydrangeas next summer, let us, therefore, make our cuttings in August from pink parents."] ]

### SIEBER, THE PLANT COLLECTOR.

FRANCIS WILLIAM SIEBER was a native of Prague, in Bohemia, and from this inland capital he succeeded in extending his botanical travels, and those of his assistants, over several distant portions of the globe, and I think that the number of specimens of plants collected thus may well be put down at one million. As is the case with Beethoven, who is said to have been a son of King Frederic William II. of Prussia, Sieber was a son of the Emperor Francis of Austria, and he certainly bore a resemblance to some of the fairer members of the Hapsburg family. His frame was well formed, and this, and the vivacity of his mind, fitted him for the task he had traced out for himself.

It was about the year 1812 that Hoppe, of Ratisbon, began to publish his "Dried Plants of Germany;" Sturm's "Flora," also composed of small, neatly-coloured engravings, excited the attention of the studious amongst us. Sieber, whose relations were in easy circumstances, had received a good school education, and studied botany under Willibald Schmidt, the author of the "Flora Bohemica," in folio. After some preliminary excursions in the Bohemian Sudets, he started for the Austrian, Carinthian, and Styrian Alps, Saussure and Hacquet being his patterns then. It was a pleasure to listen to Sieber, when he related how he first found and collected the *Wulfenia carinthiaca*, those rare *Saxifragas*, and *Gentianas*, only to be found in certain remote localities of Carinthia and Carniola; already my departed friend collected, *at in grosso*, one and two hundred specimens, if he could get them. Sieber trafficked from the first, like Hoppe, in plants, but not then to the same extent as when he published his "Flora Exsiccata Novæ Hollandiæ," &c.

Sieber's next trip was to Italy, then under Napoleon's rule, and difficult of access, especially for an Austrian subject. The "Flora Italica," was the first considerable issue of dried plants, and the printed tickets to those specimens were a curiosity in themselves. "*Ixia bulbocodium*, in rupe Tarpeja, Roma;" "*Anthyllis barba-Jovis*, in nubibus *Insulæ Capræ*;" "*Lamium garganicum*, in monte Gargano, Apulia;" &c. These issues widely diffused the love of botany, and in Bohemia produced a rich crop of distinguished botanists. Of his stay in Naples a curious incident may be related. Being in the island of Capri, he ventured himself on parts of the rocks where no one had ever been before. This, and perhaps the papers he had about him for placing his plants in, attracted the notice and suspicion of those on board some English cruiser in the Bay of Naples, and they fired several cannon shots at our botanical collector, which, however, fortunately did not reach him.

Returning to Prague from such excursions, a couple of years were occupied in arranging, naming, publishing, and

disposing of these plants. His subscribers became in succession numerous and important, amongst them the late King of Saxony, for whom Sieber collected choice specimens (*Pracht exemplare*) in all his travels. This splendid collection was probably burnt during the outbreak in Dresden, in 1849. It is natural to suppose that our friend would not have sufficed for the large amount of work connected with his enterprise, and he had about him some young gardeners to help him, and thus the idea arose, successively much expanded, to send some of these youngsters on similar botanical errands. I believe it was young Katschy whom he first sent to Martinique for that purpose. Imagine a young Bohemian journeyman gardener going to the forests and mountains of a West India island! Still those lads all turned out well, especially Boyer, who afterwards became Professor and Director of the Botanical Garden in the Isle of France. Still Sieber used a means to facilitate, nay to make possible, such botanical expeditions. There was a book prepared in small folio, and on the leaves were fixed original or cultivated specimens of such plants as were known or supposed to grow in Martinique. I was present when Katschy returned, and certainly there never had arrived in Europe such a vast collection of tropical plants for publication and sale. Sieber generally divided his "Herbaria Sicca" into centuries, which were sold for from forty to sixty or eighty florins (10 to £1) each.

As Schultes and Hacquet had directed my late friend to the alpine world, it was Tournefort who gave him his easterly direction. Sieber visited first the island of Crete, made a long stay at Canea, ascended the Ida, and as he was a man of manifold acquirements, surveyed the Labyrinth. This Cretan, as well as his subsequent Egyptian and Jerusalem voyages, appeared in print, and these volumes are even cited now. In Egypt Sieber went up to the first cataract, and many were the rare and new plants published in the "Flora Egyptiaca," as well as the "Hierosolymitana." Such travels connected with the collection of tens of thousands of plants were expensive then, but I think that the Emperor Francis had settled an allowance on him or his mother.

A few years passed again away in the arranging and publishing of these three herbaria. Besides, Sieber was in communication with most of the leading botanists of Europe—Tenore, in Naples, De Candolle, &c.; but he could never have succeeded in such a wide task, if he had viewed botany only in its dry and matter-of-fact features. Sieber read and knew the fine philosophical works which Kant, Sprengel, Willdenow, and others had published, and many were the pleasant and exciting conversations which I had with him in those rooms of his in the corridor of the old Convent of St. Jacob, in the Kleinseite of Prague. Then he would dress in some of the costumes of chamois hunters, or of Turks and Arabs, which he had brought with him.

About this time, 1817, Boyer went to Madagascar, and it may be said that he acquired even a public character with King Radama. The plants sent thence to the Museum of Vienna, the King of Saxony, &c., were surprising.

But now came the time when my late friend planned and executed his last and greatest botanical expedition—viz., that to the Australian continent. At that time specimens of wild Australian plants were rare even in England, because Banks, Solander, Brown, and Cunningham (?) had not collected specimens for publication and sale; therefore Sieber went to the Antipodes. His head quarters were Sydney, the environs of which, and Botany Bay, are rich in plants. But his enterprising spirit pushed him much further, and he was the first who explored the Blue Mountains, and the plains beyond them, shortly before discovered by Wentworth, Lawson, and Blaxland. These collections he made on horseback, not riding himself, because he was a wonderful walker, but the harvest of plants was so great, that they had to be stowed on the back of a horse. These thousands on thousands of specimens could not have been preserved in the ordinary way; but Sieber had invented an especial method to arrange and dry specimens for the herbarium.

To account for his subsequent melancholy death, it is to be stated that he was during his travels in communication with the Emperor of Austria; and when a letter arrived from Vienna, after a stay of several months in New South Wales,

Sieber returned to Europe, with a collection of dried plants, the bulk of which was contained in a number of cases, and it took again a considerable time to arrange and publish the several centuries of the "Flora Exsiccata Novæ Hollandiæ," in his house at Prague. He was altogether an exceedingly active and successful collector, because even the number of bird and other skins he brought with him was surprising. His correspondence with the first botanists of Europe increased every day, and a genus of plants (Siebera), and numerous species were called after him.

Sieber was in the habit of often writing to Vienna, and when such letters arrived, the Emperor would say, "Oh, let John (Archduke John) read them to me at table." It may be that our friend might before, and on a critical occasion, in 1820, have alluded to political events. So much is certain, that on his return from Sydney, he stated to the captain of the ship, that there were agents of Prince Metternich abroad who had orders to murder him. Sieber, like all men who have accomplished aught extraordinary, was a highly cultivated person, and at a later period, about 1827, he was occupied in a dramatic work, "Plato in Sicily." However, all his MSS. on various subjects have disappeared. His mind was now occupied with subjects extraneous to his original pursuits, and thus it cannot be surprising to find him, in 1830, in Paris, engaged in the political affairs of the French Revolution. His collections had been transferred to Vienna, and as Professor Lichtenstein (the African traveller) was in the Austrian capital, portions of it were transferred to the Berlin Museum. Then, that life-full and bright career which had begun amongst the choicest plants and flowers of the Styrian and Carinthian Alps, and had pursued its course in southern Italy, in Crete, Egypt, and New Holland, drew to a sad and melancholy end. Whether Sieber became really insane or not I cannot say, but my poor friend died (be it said to the eternal shame of the Prague authorities), in the lunatic department of the hospital of that city.

His works and plans, however, survive him to a certain degree, because some of his pupils travelled and collected in Kordofan, and other most remote places. His method of preserving, and well preserving, thousands of specimens of dried plants, is worthy of being generally known.—L.

## REPORT ON THE BEDDING PELARGONIUMS GROWN AT CHISWICK, 1864.

By THOMAS MOORE, F.L.S., SECRETARY TO THE FLORAL COMMITTEE.  
(Concluded from page 470.)

### SERIES V.—SILVER VARIEGATED VARIETIES.

#### 1. LEAVES ZONATE AND MARGINATE.

##### (a) Margins white.

*Argus*\*\*\* (G. Smith).—Moderately vigorous habit; leaves with whitish edge and indistinct pink zone; flowers very bright light scarlet, well formed, and in good trusses.

*Burning Bush* (Hally).—Dwarf habit; leaves with whitish edge and pink zone; flowers light scarlet.

*Countess of Warwick*\*\*\* (Kinghorn).—Vigorous free habit; leaves whitish at the edge and with a dark red zone; flowers abundant, scarlet.

*Elegans* (E. G. Henderson & Son).—Moderately vigorous habit; leaves white-edged and faintly pink-zoned; flowers cerise.

*Fontainebleau*\*\*\* (E. G. Henderson & Son, Scott).—Dwarf habit; leaves with a whitish margin and a faint pink zone; flowers cerise.

*Julia*\*\* (Turner).—Vigorous habit; leaves with very slight pink zone and whitish margin; flowers scarlet, in good trusses.

*Little Beauty* (E. G. Henderson & Son).—Dwarf habit; leaves very white at the edge, with a deep red zone; flowers scarlet.

*Picturatum*\*\*\* (Turner).—Dwarfish habit; leaves flat, with whitish edge and well-marked pink zone; flowers light scarlet.

*Rainbow* (Scott).—Moderately vigorous; leaves with pink zone and whitish edge; flowers light scarlet.

*St. Clair*\*\*\* (Turner).—Free and moderately vigorous

habit; leaves cupped, whitish at the edge, and having a dull zone; flowers rather narrow-petaled, in fine trusses, pale cerise pink. Also grown as Victoria.

*Silver Chain*\*\* (Scott, E. G. Henderson).—Compact dwarf habit; leaves with a broad whitish edge, flat, with indications of being zonate; flowers bright rosy cerise, large and well formed, darker than those of *Venus*, which it very closely resembles: the foliage, however, is better.

*The Countess* (E. G. Henderson & Son).—Vigorous and coarse in habit; leaves with whitish edge and dark zone; flowers scarlet.

#### 2 LEAVES MARGINATE, NOT ZONATE.

##### (a) Margins white.

*Alma*\*\*\* (Scott, Turner).—Moderately vigorous habit; leaves with a broad whitish edge; flowers deep scarlet. Of free healthy growth.

*Bijou*\*\*\* (Low & Co., Turner).—Moderately vigorous; leaves flat, with a whitish edge; flowers of good form, scarlet. Considered better than *Jane*, but of a more compact-growing habit.

*Jane*\*\*\* (Turner).—Moderately vigorous habit; leaves whitish at the margin, rather cupped; flowers scarlet. Of good free habit, covering the ground well.

*Mangles's Variegated* (Scott).—Of free spreading habit; leaves lobed, with a broad whitish edge; flowers small, pink. Useful.

*Mountain of Light* (Fraser).—Dwarf habit; leaves whitish at the edge; flowers scarlet.

*Mountain of Snow* (Fraser).—Dwarf; leaves with whitish edges; flowers loose, scarlet.

*Mrs. Lennox* (Taylor).—Dwarfish habit; leaves white-edged; flowers scarlet. The whitest-marked in the collection, but considered to be practically superseded by *Bijou* and *Jane*.

*Queen of Queens*\*\*\* (Bull).—Moderately dwarf; leaves whitish at the edge; flowers scarlet. A free grower, and dwarfer in habit than *Jane*.

*Variegated Dandy* (Scott).—Very dwarf and compact; leaves very small, with a narrow whitish edge. Useful in some situations.

##### (b) Margins cream-coloured.

*Annie*\*\* (Kinghorn).—Vigorous habit; leaves large, with a broad creamy edge; flowers scarlet, of a free and rather coarse habit.

*Flower of Spring*\*\*\* (Turner).—Moderately vigorous compact habit; leaves broadly edged with cream colour; flowers large, of good form, deep cerise-scarlet.

*Hendersonii*. (E. G. Henderson & Son).—Of rather coarse habit; leaves creamy at the edge; flowers scarlet.

*Koh-i-noor* (Scott).—Dwarfish habit; leaves with creamy edge.

*Lady Plymouth* (Turner, Fraser).—Of free spreading habit; leaves bipinnatifid, with creamy edges. An old useful sort.

*Maid of Orleans* (Scott).—Dwarf habit; leaves with cream-coloured edges; flowers pale cerise-scarlet.

*Meteor*\*\* (Dixon).—Moderately vigorous habit; leaves with a broad creamy-white edge; flowers deep scarlet.

*Silver Queen*\*\*\* (Taylor).—Vigorous habit; leaves large, round, scarcely lobed, flat, with a well-defined broadish creamy edge; flowers abundant, loose, rose-pink.

*The Bouquet* (E. G. Henderson & Son).—Moderately vigorous habit; leaves creamy at the edge, cupped; flowers dull cerise.

*Variegated Prince of Orange* (Fraser).—Dwarf compact habit; leaves small, lobed, scented, narrowly edged with cream colour.

*Venus* (E. G. Henderson & Son).—Dwarf compact habit; leaves with a broad creamy edge; flowers bright rosy cerise. Similar to *Silver Chain*, but a few shades less pure in the colour of the leaf.

### SERIES VI.—GOLDEN VARIEGATED VARIETIES.

#### 1. LEAVES ZONATE AND MARGINATE.

*Golden Baron Hugel* (Wills).—Very dwarf spreading habit; leaves with a bronzy zone; flowers scarlet.

*Golden Woodwardiana* (Wills).—Rather vigorous habit; leaves yellowish-green, with indistinct bronzy zone; flowers scarlet, of good form.

*Lottie* (Wills).—Dwarf habit; leaves yellowish with bronzy zone; flowers cerise-scarlet.

*Mrs. Milford* (E. G. Henderson & Son).—Vigorous habit; leaves with a very broad bronze-coloured zone, becoming at length yellow; flowers deep scarlet, distinct.

*Mrs. Pollock* \*\*\* (E. G. Henderson & Son).—Vigorous habit; leaves flat with a broad yellow border, and zone of deep red; flowers scarlet. A very beautiful variety.

*Sunset* \*\*\* (E. G. Henderson & Son).—Dwarfish and spreading habit; leaves smooth, flat, with a broad yellow border and distinct zone of light orange-red; flowers cerise scarlet. A very beautiful variety.

### 2. LEAVES MARGINATE, NOT ZONATE.

*Cloth of Gold* \*\*\* (Veitch, Turner).—Dwarf habit; leaves flat, downy, deep yellow, with small bright green disk; flowers deep scarlet.

*Golden Cerise Unique* (Veitch).—Moderately vigorous and free habit; leaves with yellow edge and reddish zone; flowers small, cerise.

*Golden Chain* \*\*\* (Scott; Turner).—Spreading habit; leaves broad, flat, surrounded with a deep yellow edge; flowers deep cerise-scarlet.

*Golden Fleece* \*\*\* (Veitch, Turner).—Dwarf spreading habit; leaves flat, yellow, with green disk; flowers abundant, bright scarlet. Appears to be of freer habit than *Cloth of Gold*.

*Golden Harkaway* \*\* (E. G. Henderson & Son).—Dwarf habit; leaves lobed, and having yellow margins; flowers loose, orange-scarlet, tinted with cerise.

### 3. LEAVES WHOLLY YELLOW.

*General Longstreet* (Wills).—Apparently not free; leaves yellowish; flowers scarlet.

*Golden Leaf* (Carter & Co.).—Dwarf habit; leaves yellow; flowers scarlet.

*Golden Little David* (Wills).—Dwarf habit; leaves yellow. This plant was not vigorous enough to produce flowers.

*Robert Fish* (Wills).—A gold-leaved variety, with orange-scarlet flowers of the semi-nosegay character, and highly promising as a dwarf sort for edgings, but not well developed. —(*Proceedings of the Royal Horticultural Society.*)

## CERASTIUM TOMENTOSUM—ARABIS LUCIDA VARIEGATA AS EDGING PLANTS.

I OFTEN find the *Cerastium tomentosum* mentioned and recommended as a border for Geraniums; but as my *Cerastium* has been in full flower for the last fortnight or more, while the Geraniums were only lately bedded out, I know not how these can flower together. I have a six-foot-wide border of *Cerastium* one sheet of snow, with circular patches of Geraniums at regular distances in the midst, but the *Cerastium* is so much taller than the Geraniums, that it quite smothers and hides them. Do you consider the *Cerastium Biebersteini* superior to the *C. tomentosum*? The foliage is sometimes richer, but the flowers so scattered and few that I cut them off, and doubt about using it further.

Is it sufficiently ascertained that there is a good *Arabis lucida variegata* yellow enough to look handsome, and to make it worth inquiring for from nurserymen?—AGNES.

[The *Cerastium tomentosum* is very beautiful when in full bloom, and then it would be apt to dwarf out of sight scarlet Geraniums when first planted out, unless these were very large plants. Even in your case, with circles of Scarlet Geraniums in your six-foot-wide border of *Cerastium*, the tall flowers of the *Cerastium* will shade the Geraniums in this scorching weather, and thus do good. The *Cerastium*, however, makes the most effective bordering for scarlets, blues, and purples, after the flowering is over, and the edging is nicely trimmed. One great advantage is, that you may cut it pretty well as you will. One of the finest massive edgings we ever saw was at Trentham (see account of that place in Vol. V.) Mr. Tyerman of the Liverpool Botanic Gardens also does it admirably; but in both these places the mass of white shoots was more valued than the pretty white flowers. In the damp atmosphere of Liverpool Mr. Tyerman cuts the *Cerastium* close to the ground early in spring, and when it shoots takes it up, divides, and plants in narrow rows, and then it becomes large enough during the summer. Our correspondent may therefore be glad rather than otherwise that her *Cerastium* will be a better

edging for small Geraniums without the flowers than with them.

We like the *Cerastium Biebersteini* very well, but not better than *tomentosum*, and the former is not so hardy and will not bear the knife and the shears so well as the latter. In some soils it comes very white, in others and with dripping skies it is apt to come greener than *tomentosum*. Both require bright sun to bring out their pearly whiteness. We have two little gardens on grass, each clump being edged with one or the other of these *Cerastiums*, and the effect is very pleasing and the saving of other plants in planting is great. The yellow *Arabis variegata lucida* is very good for small edgings, as distinct for the yellow markings as the other variegated one is for white markings, but both are apt to revert to the green original on good rich soil. It is decidedly worth having.]

## CRYSTAL PALACE ROSE SHOW.

As might have been expected from the extreme heat and burning sun that we have for some time experienced, the collections of Roses were both deficient in number and quality as compared with previous years. Leaving to others the task of enumerating the prizes, &c., of the general exhibition, I would confine my remarks to the new Roses of 1863 and 1864, that including, in fact, Roses from the autumn of 1862 to the spring of 1865, as Roses sent out from France in the autumn of 1862 are not sent out here until 1863, while those of last autumn are included in the lists.

Messrs. Paul & Son were placed first with a fine selection, and considering the season, an exceedingly well-bloomed collection of the following, of which the finest are marked with an asterisk. \**Duchesse de Caylus*, *Celine Gonod*, *Jean Goujon*, *Lady Emily Peel*, *President Lincoln*, \**George Prince*, *Princess of Wales*, *Bernard Palissy*, \**Alpaide de Rotalier*, *Madame Josephine Guyot*, \**Duc de Bassano*, *Gustave Bonnet*, \**Madame Victor Verdier*, *Madame Alfred de Rougemont*, \**Rev. H. Dombrain*, \**Lord Macaulay*, *Dr. Andry*, *Triomphe de Villecrenes*, *Paul Desgrand*, *Emotion*, *Comtesse de Coucy*, \**Pierre Notting*, *Louise Damazin*, *Souvenir de Comte Montault*, *Madame Soupert*, \**Laurent Descourt*, \**Gabriel Peyronny*, *Madame de St. Arnaud*, \**Leopold Premier*, *Alphonse Belin*, \**Claude Million*, \**Lord Herbert*, *Eugene Verdier*, \**Hamlet*, \**Madame Derreulx Douvillé*, *Vainqueur de Goliath*, *Madame de Stella*, *Jean Touvais*, *Amiral La Peyrouse*, *Dr. Spitzer*, *Pavilion de Pregny*, *Paul de la Meilleray*, \**Arles Dufour*, *Madame C. Doffoz*, *Abbé Berlése*, *Louise Margottin*, \**Madame Vallembourg*. *Duchesse de Caylus*, a seedling of Charles Verdier's, is one of the best Roses of this season—a lovely pinkish crimson, a shade of colour that we most want; while of those of last year *Madame Victor Verdier* and *Pierre Notting* were the best. *Arles Dufour* is a fine Rose, while *Louise Margottin* was the most delicate pink of Bourbons. *Gabriel Peyronny* and *Madame Vallembourg* were also fine, as were *Hamlet* and *Lord Herbert*, but all of that crimson shade of which we have such an abundance.

*Mr. Keynes*, of *Salisbury*, was second. His Roses were *Louise Van Houtte*, \**Alpaide de Rotalier*, \**Prince Henri de Pays Bas*, \**Centifolia rosea*, \**Baron Pelletan de Kinkelin*, *Bernard Palissy*, *Louise Margottin*, *Emotion*, *Abbé Reynard*, *Senateur Reveil*, *Triomphe de Villecrenes*, *Reine de la Pape*, \**Duchesse de Morny*, *Macaulay*, \**Claude Million*, \**John Hopper*, *Lays*, \**Rev. H. Dombrain*, *Jaune d'Or*, *Kate Hausburg*, *Madame de Stella*, *Alphonse Belin*, *Gabriel Peyronny*, *Laurent Descourt*, *Madame Soupert*, *Jean Touvais*, \**Maréchal Souchet* (Guillot), \**Leopold*, \**Joseph Fiala*, \**Lord Clyde*, *Amiral La Peyrouse*, \**Madame Freeman*, *Paul de la Mielleray*, *Abbé Reynard*, *Paul Desgrand*, *Lamartine*, *Madame Victor Verdier*. Of these I have again marked the best; *Duchesse de Morny* is a good Rose, *Maréchal Souchet* is a fine dark. *Madame Freeman* in its expanded state reminds one of *Souvenir de la Malmaison*; *Joseph Fiala* is a fine large-petalled Rose; *Claude Million*, a good dark; *Prince Henri de Pays Bas*, a good crimson; and *Centifolia rosea*, a fine rose; *Baron Pelletan de Kinkelin* is a fine rich dark Rose.

*Mr. Cant* was third. Amongst his Roses was a fine *Xavier Olibo*, a very rich dark colour, adding another to the many good Roses which *Lacharme* has given to us.

In the decorative stands the competition was confined to those of Miss March's design, with the exception of one from Mr. Turner, which was very pretty; but the *Lycopodium* used had better have been replaced by *Adiantum*. Mr. Round's gardener, was first, and Mr. Turner second. The Roses in both these stands were good, while the arrangement was excellent. It seems, however, as if no fertility of invention can devise any real improvement on Miss March's original design. One may have something to say by-and-by about the novelties amongst Roses; but, in the meantime, I think it is clear that in Duchesse de Caylus and Xavier Olibo we have a great addition to our flowers.—D., Deal.

OUR remarks on the general show will be brief, and chiefly confined to the enumeration of the principal prizetakers; for the observations of our valued contributor "D., Deal," have already told more than half the tale. The great heat of the last few days carried fear into the heart of rosarians, and Friday, with a temperature of 89° in the shade and 136° in the sun, brought dismay—so much so that many intending exhibitors withdrew from competition, and the quality of the blooms of others, who did venture to put in an appearance, was seriously impaired. This drawing back of exhibitors at the eleventh hour must have seriously interfered with the arrangements of the most active and most courteous of Superintendents, Mr. Wilkinson, but before the Judges came round all was in excellent order, and the line of tabling, though not so long as in former years, presented a fine appearance.

In Class I., ninety-six varieties, one truss of each, Mr. Mitchell, of Maresfield, was first. Victor Verdier, Madame Vidot, Maréchal Forey, Madame Rivers, Gloire de Santenay, Impératrice Eugénie, Louise de Savoie, Souvenir de la Malmaison, Baron Adolphe de Rothschild very rich in colour, Kean, Queen Victoria, Charles Lefebvre, La Ville de St. Denis, Maurice Bernardin, and last, but not least, the beautifully-formed new yellow Tea Maréchal Neil, were among the most noticeable. Messrs. Paul & Son were second with a good stand, in which were Comtesse de Chabrilant, Madame Charles Wood, Madame Vidot, Général Jacqueminot, Maréchal Vaillant, Maurice Bernardin, Lord Clyde, Triomphe de Caen, and Pierre Notting, one of the best dark crimson in the Show. Mr. Keynes, of Salisbury, was third; Mr. Cant, Colchester, fourth; Mr. Cattell, Westerham, fifth.

In Class II., forty-eight varieties, three trusses, Messrs. Paul & Son were first, and second in the following class for twenty-four varieties, with beautiful stands, in which we particularly noticed Madame Caillat, Professor Koch, François Louvat, Lord Clyde, Lord Macaulay, Madame Vidot, Alba Rosea, Madame William Paul, Madame C. Crapelet, Caroline de Sansal, and Louise Margottin, very beautiful and fine in form. In addition to the above, Messrs. Paul & Son also exhibited their new Rose Princess Mary of Cambridge. Mr. Turner was an excellent second in forty-eights, Mr. Keynes third, and Mr. Francis, of Hertford, fourth. For twenty-fours Mr. Keynes was first, having Gloire de Dijon, Louise Peyronny, Laurent Descourt, Comtesse de Chabrilant, and several others particularly good; Messrs. Paul and Son, as already stated, were second, Mr. Turner third, Mr. Cant fourth, and Mr. Mitchell fifth; the last-named had Isabella Gray, fine.

In Class IV., single truss of twenty-four varieties, Mr. Cranston, Hereford, was first with Louis XIV., Sénateur Vaise, Olivier Delhomme, Comtesse de Chabrilant, Pauline Villot, &c. Mr. Turner was second with Gloire de Santenay, François Lacharme, Duc de Rohan, Queen Victoria, and Baron Gonella, very good. Mr. Treen, Rugby, was third, and Messrs. Paul & Son fourth, with good stands.

Class V., was for single trusses of twelve varieties, and here Mr. Turner was first, Mr. Francis second, Mr. Keynes third, and Mr. Cant fourth. In the different exhibitions were some excellent examples of Souvenir de la Malmaison, Victor Verdier, Madame Victor Verdier, La Reine, and Comte de Paris.

In the Amateurs' Classes were some excellent exhibitions, especially those from Mr. Hedge, the Rev. S. Reynolds Hole, and Mr. Ingle.

In Class VI., single trusses of thirty-six varieties, Mr.

Hedge was first, Rev. S. R. Hole second, Mr. Ingle, gardener to Mr. Round, Colchester, third; Mr. Exell, gardener to J. Hollingworth, Esq., Maidstone, fourth; and Mr. Bristowe, gardener to G. Orme, Esq., fifth.

Class VII., twenty-four varieties, was also very good, especially the exhibitions coming from Mr. Ingle and the Rev. S. R. Hole, which had the first and second prizes; Mr. Smith, gardener to T. Monson, Esq., Leyton, was third; Mr. Hedge fourth; Mr. E. B. Postans, of Brentwood, fifth; and an extra prize was awarded to Mr. Hunt, Leicester.

In Class VIII., eighteen varieties, single truss of each, there were likewise several meritorious collections. Mr. Hedge again took the first place; Mr. Dennis, gardener to H. Hayward, Esq., Folkington, was second; Mr. Bristowe third; Mr. Chard fourth; extra Mr. King.

In Class IX., twelve varieties, Mr. Bristowe was first, Mr. W. Smith second, Mr. Ingle third, Mr. Postans fourth, and Mr. Hunt had an extra prize.

Of Roses in pots there were only three collections, two of which, in good condition considering the weather, came from Messrs. Paul & Son, who had a first prize for twenty-five in eight-inch pots, and a similar award for twelve sent out in 1864. Mr. Francis was second for a collection of twenty-five.

The day was delightful, and, as usual at the Rose Show, the crowd of visitors was so great that the tables could only be approached with great difficulty, and long and patient waiting; especially was this the case where the Nurserymen's collections of forty-eight and twenty-four were shown.

## ROYAL HORTICULTURAL SOCIETY.

JUNE 24.

A FLORAL Decoration Show was held this day, prizes of the value of ten, seven, and three guineas being offered by Sir Wentworth Dilke, Bart., for the most tastefully decorated dinner-table laid out for twelve persons. The Judges were Lady Caroline Kerrison, Lady Margaret Chateris, the Hon. Mrs. Rose, and Mrs. E. Bowring, assisted by Mr. J. E. Millais, E.A., Mr. Richard Thompson, and Mr. J. H. Pollen. The first prize was awarded to Messrs. W. & G. Phillips, 155, New Bond Street, for an arrangement in which Minton's china, of several beautiful designs, largely entered. The centre piece consisted of three female figures supporting a circular basket filled with Grapes and other fruit, resting on moss and Ferns; but the chief novelty lay in small glass tubes for holding water and flowers being supported all round, so as to form a festoon, by means of metal bands made to resemble tape. The two end pieces were also figures in Minton's china, forming elegant candelabra, with four branches, in which rose-coloured wax candles were set. Other end dishes were filled with fruit, and the whole was set round with baskets made of the same kind of china filled with fruit, flowers, and Ferns. A mirror at the base of the central figures supported a tripod glass stand of flowers. The frame was of metal, and perforated to admit flowers; and the plates which were set for the guests had three holes at the edge for holding water and flowers. The second prize was awarded to Mrs. Dalton, of Ealing, for a design consisting of Petunias, White Roses, Scarlet Geraniums, and Corn-Flowers crossing each other diagonally, and the centre a basket of fruit. The whole was very simple and permitted of the guests seeing each other and conversing, but the arrangement did not seem to us very pleasing. The third prize went to A. Chapman, Esq., 22, Norfolk Street, Park Lane, for an elaborate design, the principal pieces being of glass and set on a mirror. That in the centre had two dishes, the lower one filled with Delphiniums and Ferns, having also three flower-tubes springing from it; the upper one filled with Roses, Stephanotis flowers, and Ferns. At each end was a glass stand about 20 inches high, containing Grapes, Peaches, and other fruit, and two more at each side containing *Aerides* and other Orchids. The mirror was surrounded by the flowers of *Stephanotis floribunda*, and Roses with their foliage. Messrs. Dobson & Pearce, of St. James's Street, were highly commended for an exhibition in which what is called a Grecian tripod glass stand was very elegant and different from those generally employed; and a similar stand was employed by Mrs. Thompson, pendant

glass baskets being attached by a wire hook to the body of the stand. Mr. Naylor was commended for an arrangement consisting of a central circle in which the glass flower-stands were surrounded by spar and Ferns, and an outer circle for water and flowers. The whole was novel and rather pleasing.

The prizes offered to ladies by the proprietors of the *Gardeners' Chronicle* for plants grown in a room—viz., £10 for the best Orchid in bloom, and £10 for the best flowering or fine-foliaged plant, brought forth a good competition. Miss Williams, Sutton House, Highgate, took the first-named prize with a very good *Aerides affinis*; and Viscountess Doneraile had the other for a basket containing a fine plant of *Alocasia metallica*, *Gymnostachyum Verschaffeltii*, *Dracæna Cooperi*, and a *Caladium*. We noticed besides a good plant of *Lycopodium cæsius* from Mrs. McKenzie, Alexandra Park, a fine *Adiantum cuneatum* from Mrs. Dombrain, and some good *Oncidiums* and *Cypripediums*.

### PRETTY CANADIAN WILD FLOWERS.

BEFORE the last patch of snow has melted from the hillside the beautiful little Mayflower (*Epigæa repens*), bursts its buds, and dots its dark glossy leaves with pretty pink flowers, as it creeps over the granite boulders, and peeps out here and there on the mossy banks. Then come the modest little Hepatica, the yellow Dog's-tooth Violet (*Erythronium americanum*), the Blood-root (*Sanguinaria canadensis*), used as a dye by the Indians, the purple Trillium (*T. erectum*), and the painted Trillium (*T. erythrocarpum*). In more open places, and by the roadside, may be found the Spring Beauty (*Claytonia virginiana*), whilst down on the sandy beach of the St. Lawrence is to be seen the elegant fairy Primrose (*Primula mistassinica*), a perfect little gem, pale lilac in colour, and so small that a plant in flower may be potted in a thimble.

A little later, and the woods are gay with the Star-Flower (*Trientalis americana*), the Bunchberry (*Cornus canadensis*), the Columbine (*Aquilegia canadensis*), the Clintonia borealis, with its rich glossy leaves and pale yellow flowers, the Dicentra (*D. canadensis*), and the Corydalis (*C. glauca*).

As the month of June advances the swamps contribute their share, and yield in profusion *Kalmia angustifolia*, and, still later, *K. latifolia*, Labrador Tea (*Ledum palustris*), *Rhodora canadensis*, Pitcher-plant (*Sarracenia purpurea*), Cranberry (*Vaccinium oxycoccus*), *Cypripedium acaule*, *Smilacina trifolia*, *Pogonia ophioglossoides*, *Calopogon pulchellus*, and several of the more common varieties of the Orchis.

In the woods we have the yellow Lady's Slipper (*Cypripedium pubescens*), one or two varieties of Wintergreen (*Pyrola*), the Prince's Pine (*Chimaphila umbellata*), and the beautiful *Linnaea borealis*, trailing so gracefully over the moss-covered logs.—(*American Gardener's Monthly*).

### THE YORKSHIRE GALA.

WEDNESDAY and Thursday, the 14th and 15th of June, were the days fixed for the seventh year of the York Gala and Floral Fête, held in the grounds of the Bootham Asylum.

The show of plants and cut flowers has each year gone on improving, and this year the display of Pelargoniums, stove and greenhouse plants, and ornamental-foliaged plants was exceedingly good. One of the most interesting features of the Show were the collections of cut Roses, which were brought together by the additional prizes offered by the Committee this year, with the hope of inducing some of our principal Rose growers to compete; and although, owing to its being too early in the season, our northern Rose growers were not represented, yet the Committee have every reason to congratulate themselves on the exceedingly fine display of Roses shown, and all the space we can spare is for some notes on them, for, as is usually the case, when a good collection of cut Roses is exhibited, they proved the most attractive feature in the Show.

In Class 27, for forty-eight varieties, single blooms, Mr. Keynes, of Salisbury, was first; Mr. R. B. Cant, of Colchester, second; and Mr. E. P. Francis, Hertford, third. There were no other competitors. Mr. Keynes was *facile princeps*. The race between Mr. Cant and Mr. Francis was much closer, the number of good blooms in each tray being nearly

equal; but one or two inferior ones occurred in Mr. Francis's collection, which gave Mr. Cant the second place. Mr. Keynes's forty-eight were, to take them as they were staged, Madame Hector Jacquin; Madame Joseph Guyet, a good new Rose; Mlle. Bonnaire, too small; Madame C. Joigneaux, too open; America; Maréchal Suchet, good; Alpaide de Rotalier, a very fine bloom; Senateur Vaisse, good; Cloth of Gold, very good; Madame Pauline Villot; Comte de Nanteuil, good; H. Laurentius, moderate; La Ville de St. Denis; Olivier Delhomme, very good; Anna de Diesbach, too far gone; Madame C. Wood, very good; Baronne Gonella, good but a little sullied; Prince Camille de Rohan; Louis Van Houtte, new; Madame Vidot; Charles Lefebvre; La Tour de Crouy, an enormous Rose, but apparently not likely to open well in damp weather; Parmenier, moderate; Devoniensis, splendid; Madame Victor Verdier; Vicomtesse Douglas, too loose; Général Jacqueminot; Caroline de Sansal; Maurice Bernardin; Sœur des Anges; Souvenir de C. Montault; Louise Peyronny Souvenir de Malmaison, too far gone; Madame Boll; Evêque de Nîmes, very fine; Madame Furtado; Louise Margottin, both very fine; Duchesse d'Orleans, too loose; Madame Boutin; Lord Macaulay, a splendid bloom; John Hopper, almost equally fine; these two Roses were superb, and prove that our French raisers will have to look well to their laurels, as Lord Macaulay is equal if not superior to any French Rose in that class; François Lacharme, good; La Fontaine, too loose; Madame Vigneron; Maréchal Vaillant, too small. There were two or three others whose names we forgot. On the whole the collection was first-rate, though, as the blooms were fully expanded when they were first staged, the heat of the tent soon caused some of them to open too much.

Mr. Cant was second. Among his blooms we noticed some very good specimens of Souvenir d'Elise (Tea), Madame Hector Jacquin, Prince Camille de Rohan, Colonel de Rougemont, rather too light; François Lacharme, Mathurin Regnier, Comtesse de Kergolay, Evêque de Nîmes, Princess Marie, Keane, Elise Sauvage, very good in colour; Eugène Appert, President (Tea). We especially noticed that all the Tea Roses in Mr. Cant's collection were good. Madame C. Wood, Madame Caillat, Gloire de Chatillon, and Vicomte Vigier were hardly up to the mark. We remarked a curiously striped bloom of Comtesse Cecile de Chabrillant in Mr. Cant's collection, which is no improvement.

Mr. Francis was third with exceedingly good blooms of Anna de Diesbach; Louise Peyronny; Cloth of Gold; Louise Margottin; Isabella Grey; Joseph Fiala, rather small. There were also good blooms of Pauline Lanzeteur; Smith's Yellow; Auguste Mié; Eugène Appert, rather faded but of good form; Gloire de Dijon, curiously marked with pink from the sun. General Washington, Charles Lefebvre, Caroline de Sansal, Madame Furtado, Victor Verdier, Marie Portemer were none of them up to the mark.

In thirty-sixes, Mr. Keynes was again first; Mr. Treen, of Rugby, second; and Mr. Cant, third. In Mr. Keynes's collection were some splendid blooms of Baronne A. de Rothschild, the best we have seen of it yet; Charles Lefebvre; Alpaide de Rotalier, a great acquisition, a clear satiny pink with fine form and smooth petals; Lord Macaulay; Madame Boutin. Gustave Rousseau, a good Rose, but rather too loose in form, and thin, John Hopper, Triomphe des Rennes, and Comtesse Ouvaroff, were also very good, Madame Clemence Joigneaux was too far gone, it wants to be shown before it is fully expanded; Madame C. Wood and Beauty of Waltham, both very good, but too much alike; Rev. H. Dombrain, a good new Rose, somewhat like Catherine Guillot. Among the light Roses in this collection, Sœur des Anges, Madame Vidot, and Madame Vigneron, were all good, but none of the blooms of Sœur des Anges in any of the stands was as good as it ought to be. There were some good blooms in Mr. Treen's collection, who was second for thirty-sixes, but they were badly named and not judiciously staged. Jean Goujon appeared as Jan Jougon; Caroline de Sansal, was called Catherine de Sansal, &c. We should advise Mr. Treen to take more pains both in staging and nomenclature. Mr. Cant was third in this class, but we did not remark any blooms which were not shown in his forty-eights, which were a superior collection.

In Class 32, a prize of £5, given by W. Dove, Esq., Crown

Cottage, York, for twenty-four distinct varieties, in trusses of three with foliage and buds, there were three competitors, and the first place was again easily obtained to Mr. Keynes. Amongst these were some splendid blooms of Comtesse Ouvraro; Gloire de Vitry, Madame Knorr, Madame Charles Wood, Comtesse de Chabillant, Souvenir d'un Ami, Victor Verdier, and John Hopper. The only decidedly bad blooms were La Fontaine, all three of which were loose and open.

We have not much space to accord to the amateur classes. There were many competitors for sizes and twelves; Mr. Evans's twelve being very good. In eighteens, the competition was not so close. Mr. Perry was first with good blooms of Charles Lefebvre, Paul Ricaut, Jean Goujon, John Hopper, Madame Boll, and Senateur Vaisse. As a general rule we may remark, that the Roses in the amateur classes were not shown sufficiently fully expanded; for though many Roses are prettiest when half opened, yet in an exhibition of Roses we are of opinion that those which keep their form and shape when fully opened will always bear off the palm against mere buds, and it ought to be the object of Rose growers to select those which are best when fully expanded, and which are more likely to prove of general service in our flower gardens.

There were four classes for Roses in pots, but none that were very worthy of remark, as the hot weather had been too forcing, and the colour of the Roses was not good; a plant of Charles Lawson was the best.

We have not space at present to particularise the other features of the Show, but we cannot pass over the splendid collection of Pelargoniums shown by Mr. May, of Bedale, who easily distanced all competitors. Amongst the Fancies were splendid plants of Exquisite, Madame S. Dolby, and Countess of Waldegrave. His twelve English Pelargoniums were—Ariel, Lord Clyde, Viola, Rose Celestial, Gem of Roses, Saracen, Desdemona, Admirable, The Bride, Leander, The Belle, and Sir Colin Campbell, which were all equally good. Mr. Steward also showed six first-rate plants in the amateur class—Leviathan, a very large flower; Desdemona, Rose Celestial, Lucifer, Majestic, and Viola. The Hon. Payan Dawney also showed some fine plants of Fancies, among which were Celestial, very good, Sweet Lucy, Cassandra, Cloth of Gold, &c.

We noticed an error in judgment in the class for six Fuchsias. Those which obtained the second prize were not named, and in them were two plants of Souvenir de Chiswick, and two of Venus de Medici. In first-class shows we should be inclined to disqualify all plants which were not named, as it is very easy in a large collection for two plants of the same sort to be shown, and yet pass the judge's eye. In the same tent were collections of twelve Geraniums for bedding purposes, eight of which were to be variegated. These were not shown at all up to the mark; and we should be inclined to limit the size of the pots, as some were shown in small pots and others in very large, in some cases the plants not being nearly large enough to cover the pots. There were also prizes offered for collections of twenty bedding plants, excluding Geraniums. The first prize was awarded to the largest plants, but there were some inferior plants, amongst them a white seedling Petunia, and a pot of variegated Sage, being each equally poor; the collection which was placed second was more compact and more like bedding plants. There was nothing very novel in any of the collections unless we except Iresine Herbstii, or Achyranthes Verschaffelti, which promises to be an acquisition. We must not pass over in this tent some blooms of Pansies exhibited by Mr. Dean, of Bradford Nursery, near Shipley, amongst which were Mrs. R. Dean, raised, we believe, by Downie, Laird, & Co., which is a great acquisition. Amongst the Fancies, were Princess of Wales, very good; Prince of Wales, a very handsome bronze and yellow with dense blotch; Amy Hogg; and Princess Alice, which still keeps its position amongst the Belgian Pansies.

We cannot conclude without a few remarks on the splendid collections of stove and greenhouse plants shown by Mr. Micholls, gardener to Mr. Baines, of Summerfield House, Bowden, Cheshire. He was placed first both for twelve stove and greenhouse plants in bloom, and for ornamental-foliaged plants, amongst which there were some good specimens of Anæctochilus, Sarracenia flava and purpurea; and two very handsome Crotons, especially the Croton variegata longi-

folia. Amongst his collections of plants in bloom were two very fine Azaleas, Gledastanesi and another; three Ixoras, coccinea, javanica, and aurantiaca, all in splendid bloom. We also noticed Phænocoma prolifera, and Acrophyllum venosum. A very fine collection of six stove and greenhouse plants was exhibited by Mr. Davidson, gardener to G. J. Yarborough, Esq., of Heslington; they were Rhynchospermum jasminoides, well bloomed; Allamanda Schottii, Erica ventricosa, Polygala Dalmaisiana, Stephanotis floribunda, and Medinilla magnifica. A very fine plant of Clerodendron Thomsonæ was shown by J. E. Pease, Esq., Haslewood House, Hull, the contrast of its scarlet flowers and white calyx producing a very pleasing effect.

We may congratulate the Society on the excellence of the Show and the general arrangements of the tents. The weather, too, was all that could be desired. We shall hope another year to see a better competition for bedding Geraniums and bedding plants, as these classes were introduced into the schedule for the first time this year; and we should be inclined not to limit the numbers to eight or more variegated, but to leave it to the option of the exhibitors to send what proportion of bedding Geraniums, whether plain-leaved or variegated, they thought fit.

#### VISITS TO GARDENS PUBLIC AND PRIVATE.

J. F. LOMBARD'S, ESQ., SOUTHSIDE, RATHGAR, DUBLIN.

THERE are some words and places which bring with them so many associations, that no matter how interesting may be the objects which at present surround them, they are lost in the far deeper interest of the past; and so, although I stood in a garden where there was much to greatly please me, yet I could hardly for a moment forget the scenes which its situation on the banks of the Dodder called up to my memory. How little do we appreciate the dream character of our life! nor until years begin to tell on one to see how vain are all its pursuits, how unstable the friendships we form, how changing the character of our own thoughts and feelings, how much the "I" of forty-five differs from the "I" of twenty. How well if that difference be all in the right direction, and we be given to be more anxious for the "home beyond!"

Well, I must not sermonise, but write a few lines about Mr. Lombard's garden. Mr. Lombard is known to many in England as one of the most successful growers that Ireland possesses of the Gladiolus and the Rose; and as these two flowers are favourites of mine, I was anxious to see how they were grown, and whether their appearance justified auguries of success again.

The situation of Mr. Lombard's garden reminds me not a little of that of Mr. Radclyffe's at Rushton—on a bank facing the south-west, although the advantage as far as soil, climate, and shelter, is decidedly on the side of Mr. Lombard's. This similarity has led Mr. Lombard, perhaps, to derive so much profit from Mr. Radclyffe's disquisitions on the Rose. At the bottom of his garden there is a fine stream of water, so that, as the Yankees say, he has great water-privileges. The garden itself is an old-fashioned one, laid out in great part in those small, square, Box-enclosed beds which were once so popular, and which at one time doubtless contained many of those fine, much-loved, herbaceous plants, so long neglected, but for which there is now a revived taste. At present these are filled with dwarf Roses; and the number of plants of the queen of flowers dispersed throughout the garden is upwards of two thousand. Mr. Lombard grows each variety as standards and half-standards on the brier, budded dwarf on the Manetti, and on its own roots. He has thus an opportunity of testing it in every way, and to decide as to how to grow it for a permanency. He is, like most rosarians, a great lover of the Manetti. It would be useless to enumerate the kinds which he considered the best, for they are the same which we esteem on this side of the Channel.

In Gladioli Mr. Lombard's garden is very strong. His choice beds contain about four hundred roots, and in these he had not had above seven misses, showing that the notion that there is a difficulty in growing and saving the bulbs of this fine flower is a nightmare. I may mention, too, that

in my own garden I have planted upwards of three hundred bulbs, and that I have not in a bed of 250 roots more than three misses, and the roots are to a great extent my own saving. Mr. Lombard's collection comprises the best of English and French varieties, and some good seedlings of his own. Of the new ones of this year he has four or five roots of each; and as he is a friend of Mr. Standish's he has also some of his finest and choicest varieties. He quite agrees with the notion which I have maintained about the Gladiolus—that no bulb takes stronger feeding than it does. He not only thoroughly manures his beds, but also gives them a good deal of liquid manure. Living as he does close to the Dodder, he obtains some of the drift sand which the floods wash down and leave just in front of his garden, and mixes this with the soil; but I am persuaded that if the soil be light and rich this is not necessary. As in every other flower, we can lay down no positive rules for every garden, but every cultivator must decide upon his own requirements. Let me advise every one, however, who is growing them this year to give them a liberal supply of water. I should be myself chary of liquid manure this very hot weather, but should give copious waterings every day when the plants are showing for bloom. Mr. Lombard provides against their being blown about by placing stakes at intervals in the beds, and then twisting list (the edgings of cloth and flannel), in and out amongst the plants, so as to enclose each stem in a loop. This is done at three separate heights, and so prevents them from being blown about, and the stalk from being broken. Shading he never resorts to, and indeed few flowers need it less than the Gladiolus, as it stands the weather very well, and shading to a great extent takes the colour away. As to varieties, he spoke favourably of the following seedlings of Mr. Standish:—Samuel Weymouth, Sir Walter Scott, Carminata, Eleanor Norman, The Colonel, Mrs. E. Nott, Basil, Lucy Neal, and Ensign. And of Souchet's, amongst older flowers Achille, Napoleon III., Ophir, Princess Clothilde, Linné, Pline, Comte de Morny, were pronounced good; while John Waterer, Princess of Wales, Flora, and Impératrice Eugénie were considered amongst the best of the newer varieties. With regard to what are called "winged" flowers, when the oppositiflorus blood is more strongly present, he said a good deal may be done to bring them more to a face by pressing the flowers together when they are just showing bloom; but at the same time he agreed with me that the time must come when winged flowers must be dispensed with.

The fruit trees in Mr. Lombard's garden were in fine order. Cox's Orange Pippin was largely planted, and considered by him to be the best Apple grown. That fine Apple, the Irish Peach, was also considered well deserving of cultivation. It is indeed a most delicious Apple, little known in England, but when eaten from the tree nothing can be finer. One Beurré Diel in a corner of the garden was a match for Mr. Radelyffe's Peach trees. It had borne last year as many as 400 fruit, and after keeping 150 for his own use, the residue had been sold for £3 10s., and this year the crop is again full. Mr. Lombard has also some nice Conifers; and in an old greenhouse, which is now to give way to a larger one, there were some fine pans of seedling Gladioli, sowed from the best flowers carefully impregnated, from which he expects great things.

Altogether I enjoyed, as only a florist can enjoy, the sight of many things that showed Mr. Lombard to be an excellent and enthusiastic grower; and he is, moreover, a genial and hospitable amateur. On some points we were wide as the poles asunder; but this did not prevent our having a pleasant and agreeable chat, and of, I believe and hope, mutually enjoying one another's society.—D., Deal.

**GREAT CONTINENTAL ROSE SHOW.**—On the 9th of July, there will be held at Brie Comte Robert (Seine et Marne), a Rose Show on a scale far surpassing anything we are accustomed to see in this country. Brie Comte Robert is the great centre of Rose rearing and Rose culture in France, and English nurserymen and amateurs may not be aware, that from this district the Paris nurserymen draw their supplies. When we state that the growers have an extent of somewhere about a million and a half of Roses to cut from, we may form some conception of the extent of the exhibition.

## MY PLANTS,

AND HOW AND WHERE I FOUND THEM.—No. 5.

I ASSURE you I felt "everlastin' sorry" I ever quitted our pretty home in the old country village, with its kindly faces always ready to give us a greeting, for the uncertain welcome we might receive amongst strangers. However, "it's a long lane which has no turning," and ditto a voyage which has no end. Morning dawned at last, certainly cold and grey the dull light stole over us, but still sad, indeed, must be the heart to which hope comes not with returning light. There was less straining and creaking of the good ship's planks, less booming of the angry waves, and a feeling of security began to circulate amongst us. Totally regardless of my companions or children, and thoroughly exhausted in mind and body, I fell into a busy and unrefreshing slumber, from which I was soon awakened by the joyful news that we were within sight of the town of St. Helier's. In consequence of the severity of the weather, the steamer was unable to enter the harbour, and we were landed at the pier in boats, amidst the congratulations and cheers of the crowd which had collected to welcome the overdue mail.

Solacing ourselves, after the English fashion, with a good dinner at the hotel, my husband left me to rest awhile, whilst he perambulated the town and neighbouring fort. I must not, I suppose, in a publication devoted to botany, give any further details with regard to the religion, manners, or customs of the islanders, or of their civil and military history, all very interesting topics to lovers of history, and of the past. I may, however, be allowed to speak cursorily of the soil, fertility, and natural productions of the country. The former is generally composed of a light, sandy, yet highly productive earth. Scarcely a specimen of limestone or chalk has been found in the island. This makes good the rule, that "nothing of a calcareous nature has ever been discovered there." In fact, the whole island is a mass of stone, the higher parts of which are but thinly covered with sand, and the *débris* of rock, which are driven over the tops of the highest cliffs by the strong gales from the sea. The valleys have many feet of vegetative earth, and are extremely fertile, and we were much struck in the early part of the summer by the pretty streamlets which trickled down from between the fissures in the rocks, and gladdened the flowers and Ferns beneath them; during the hotter months these fertile sources failed. The chief anxiety of the farmer in the spring seemed to be the cultivation and securing in its perfection the early Potatoes, for the supply of the London markets. The sides, or *côteaux*, as they are called, of the hills present quite a gay and holiday appearance during the Potato harvest, if I may so term it, for something after the fashion of the American "bees," do these island families help each other in a press of work—unlike our American neighbours, however, in one point, which is, that whilst "brother Jonathan" works first and plays afterwards, the Jerseyman will have his bottle of spirit at hand, and often so frequent are the visits to this all-powerful medium, that his own spirits are raised to the most hilarious pitch, and frequently the finale is a fight between these well-meaning friends, and as a natural sequence, a finale also to the day's work, perhaps quite early in the afternoon. These *côteaux* also yield "timber, Broom, Gorse, Fern, and where neither too steep nor too rocky, tolerable pasture."

Very little corn is grown in Jersey, as it can be brought from the foreign markets cheaper than the inhabitants could grow it themselves. The soil will, however, produce all the farinaceous kinds of grain. Many hogsheads of cider are annually manufactured in the island, and at the end of the spring, when the orchards are a mass of blossom, a drive through the numerous roads and lanes which intersect each other in all directions, is a treat which all lovers of the picturesque might envy. I remember during our residence with a French family in the parish of Trinity, we often had a delicacy placed upon our tea-table by Madame our hostess, called "black butter," it was a kind of black preserve, of peculiar flavour. I was informed by the loquacious donor that it was a concoction made of Normandy Pippins, butter, and I suppose sugar. I propose at some not far distant time to obtain the receipt for this same dubious-looking, yet pleasant mess. Whilst speaking of the tea-table and

its adjuncts, I may mention that Jersey was famed in years gone by for its honey. Amongst the farmers, also, the favourite drink was mead. Now, the apiaries are much fewer in number, but I should imagine from the mildness of the climate, and the great variety of herbs which are found on all sides, that the bee-keeper might realise a very good profit from his busy little family. Clover with its deliciously-scented blossoms, and Lucern, are cultivated to some extent, and would, no doubt, help to fill the combs of the colony of workers.

Whilst residing in the parishes of St. Helier's and Trinity, we did very little in the botanising line, for it was too early in the year, and besides that we did not yet know the island sufficiently well to be able to economise our time; but subsequently after locating ourselves in St. Saviour's, we spent the months of May and June in the most enjoyable rambles possible. Our plan of action was to pack up a basket of provisions directly after an early breakfast, not omitting an interesting book of some kind, and off we started, either for a day's stroll amongst the woods, and through the innumerable roads with which the island abounds, and which are lined with over-shadowing trees, the bank's sides being covered with the pretty Irish Yew; or we turned our steps towards the sea coast, generally selecting the northern side of the island, encamping at Bouley Bay, Rozel Bay, or Grève de Lecq; the latter place is rich in marine Grasses, and the scenery charming. Here are caves quite as worthy of notice as the far-famed caverns of Plemout and La Maye, one is perforated, and extends in length about 100 feet. It is, in fact, a subterranean passage, which cannot be explored when the tide is up. Another, "which lies under a hill on the western side of the bay, the mouth of which is an opening nearly 20 feet in height, rises from the entrance to a considerable degree of elevation, and penetrates horizontally to the depth of 50 or 60 feet." When illumined by the rays of the sun, and looking outwards from the extreme depth, it conveys the idea of a church, with a lofty vaulted roof. It was in the sands close to this spot that I came upon the *Elymus arenarius*, Upright Sea Lyme Grass; the *Triticum loliaecum*, Dwarf Sea Wheat Grass; and the *Rottboellia*. I thought this latter one of the stiffest-looking Grasses I had ever seen, there is something so quaint and old-fashioned about it. What the connection of ideas in my mind can be, I know not, but in thinking of it, I think, too, of Eliza Cook's poem, "The Old Arm Chair." Certainly there is no intimate connection between a grass and a chair; but I picture the "old arm chair" as a thing of stiff and formal design, with plenty of corners for the children to break their noses upon, and the *Rottboellia* with its formal name and appearance, is put in the category of my ill-regulated mind as akin to the antiquated piece of furniture aforesaid.—ALICE.

#### CUTTING ASPARAGUS.

I HAVE always thought that the practice of keeping Asparagus continually cut, whether fit for table or not, was erroneous; but my attention has lately been called to a remarkably good plantation that has been managed for years upon that plan. Every bit of it is cut as soon as it shows above the surface, whether wanted for table or not, until cutting for table is given up, when it is allowed to grow away. The plantation is very thick indeed, and, I am informed, produces very excellent Asparagus for table. One of the beds is rested every year, and as there are nine beds in the plantation, each bed is rested in turn, but every ninth year. Now, as the superior quality of the "grass" is attributed to the system of keeping it all clean cut off, I wish to inquire if such a practice is sound in theory? If so, how is the Asparagus an exception to the general rule or principle, that the continual cutting down of any plant weakens its energies, and if the practice is continued beyond a certain limit will eventually kill it?—J. K.

[The whole subject is an interesting one, but it pretty well comes under the same rule of circumstances as the cutting off and the saving of the old leaves of Strawberry plants. In fine, light Asparagus ground we would cut more and cut longer, than in stiff, heavy land. There can be no doubt that continuous and complete cutting would eventually kill the Asparagus, just as it would Rhubarb, and,

as we have proved, will kill the worst of all weed roots, the white Bindweed. In practice, if we could manage it, we would prefer not to cut a bed of Asparagus that we intended to take up and force, because in such a case the buds would be sooner matured, and the whole plant placed in a state of rest sooner, so as to be aroused into fresh energy more easily. Unless for such a purpose, we see little use in the rest every ninth year. From forcing and rotation cropping ours seldom attain any such age, though when well established and properly treated with manure, &c., there need be no reasonable limit to the productive powers of a bed. In cold, stiff soils, it would be advisable to cut all at first, and then allow the weaker to grow, to make sure of buds ripening for next season, even though there should not be too many of them; but in light, rich land, in which the Asparagus delights, it will often be the best plan to cut all that comes regularly, until Peas begin to come in. If you leave the weaker as you cut the stronger, the shoots left will take the running of the plant, and finer buds will be formed than if you had a greater number of shoots. If in such favourable circumstances you cut all, the plant is stimulated to throw up a mass of shoots, and though these may be rather small at first, they will gather strength and firmness, and form at their base a whole army of buds for next season. If the beds were all cut far into the season, the shoots would be so small and ill-ripened, that the buds would be deficient in organic matter, and if the process were continued the produce every year would deteriorate more and more. The cut-all principle if not continued too long, we have no doubt answers well in the light rich ground about Fulham and Battersea, but the cutting must not be continued so long, in cold, stiff soils, because the plants cannot produce fresh shoots and ripen them so quickly. In the latter circumstances it will always be good policy to let the Asparagus grow as soon as Peas can be obtained. What say our coadjutors?]

#### CACTUS CULTURE.

THIS tribe, to be grown in great perfection, requires moisture and dryness. The point is to give each as it is most needed. We used at one time to grow a rather large collection of these succulents, and we feel inclined to take to them again if we have a chance. Many of us find it necessary to vary the plants of which we make a hobby for a time; and we used to go on with the Cactus and *Cereus* tribe, until those most interested became tired of their gaudy colours. The greater part of them originally (for there are now beautiful hybrids), came from South Africa, where they are found in abundance festooning rocks and other dry places, their roots penetrating into the interstices of the rocks, and their succulent stems pretty well reduced to a mummy state by the intense heat of a cloudless sun and an arid atmosphere. A period of downpouring rain succeeds, and the roots and stems absorb the moisture, so that the stems become succulent with juice instead of being like thongs of dried leather. Then follows another drying period, in which the stems are again deprived of their moisture, and what is technically called ripened—that is, the growth made becomes indurated. When the moist season comes again the stems swell and are covered at every angle with the beautiful flowers. Now to thoroughly succeed we must take a lesson from Nature, and give to this succulent tribe a period of rest and a period of growth. One great drawback is that at no time have we the command of the sun of South Africa, and to make matters still worse we are forced to use our summer chiefly for excitement and growth, and our dark winters chiefly as the season of rest. When the best results are to be aimed at, the plants must be matured and partly rested under the bright sun of autumn, and then they will bristle with flower-buds, when we either force them with moisture and heat in early spring, or allow them to come more naturally in early summer. By acting on this system some farmers' daughters have bloomed them in such perfection as to tell me they thought they now could rival their instructor. They even succeeded admirably with *Cereus speciosissimus*, a rough-looking species, and its spines very dangerous for some hands. If you succeed with that none need beat you.

Now, let us go into a few details of practice, all based on the facts alluded to above. Here is a nice little plant green and flourishing, but the stems are rather too flabby, and lead you to suppose it has had too much moisture. The drainage, therefore, is examined, a quantity of the old soil taken away, and a nice clean pot given. No plants are too careless of soil. Sandy loam, loam and peat, loam and lime rubbish will grow them admirably, but my preference as to compost would be equal parts of sandy loam, brick rubbish, and old, sweet, dried cowdung. After potting—say in June, water and give all the sun you can to the plant, keeping it inside of the house or window. Water on till August whenever the plant wants it, as you would do a Geranium, not watering when the plant does not require it, nor yet allowing the stems to shrivel or shrink in the least. If the autumn is bright and sunny place the plants outside the window by the middle of August, or in front of a fence or wall facing the south. Keep giving a little water until the middle of September, but a skiff over the stems will be better than much at the roots. From the middle of September I would give all the sun possible, and not a drop of water unless the plants showed signs of distress, and then I would damp the stems instead of the roots. By the middle of October the plants should be placed in-doors, and if the temperature ranges only during winter from 38° to 45°, they will rarely need any water all the winter. The atmosphere at that temperature will supply them with enough of moisture. When you wish them to grow and bloom syringe the stems, give them a rise in temperature, and as soon as there is the appearance of a pin-head of bloom, give a little water to the roots, increasing the quantity gradually as the buds swell. After flowering again follow the above process and success will be obtained.

Considering their beauty and the very little trouble they give, these succulents deserve to be extensively cultivated by those who have little time to spare, and who from their avocations cannot give that regular attention which most other plants require. Let the above leading principles be kept in view, and extra heat, and extra cold, provided there is no frost, and a little excess of moisture or of dryness now and then, will never injure these beautiful and accommodating succulents.—R. FISH.

## THE PLEASURE GROUNDS OF PARIS.

(Concluded from page 384.)

RETURNING now to the entrance at the end of the Avenue de l'Impératrice, and following the road which lies before us, we arrive in ten or twelve minutes at the extremity of Lake Inferior, which here presents a dazzling perspective. This extensive sheet of water, covering an area of 14 acres, is 1272 yards long, 113 wide, and from 3 to 6 feet deep. Above its surface rise two small islands of which the united area is about 6½ acres; the larger, to the north, containing 3a. 3r. 12p. and being 457 yards in length; and the smaller, to the south, is 366 yards long. These two islands are united by a rustic bridge, which in summer is covered with various climbing plants, and harmonises well with the chalet or Swiss cottage which stands close by under the shade of a clump of old Pine trees, which cover the upper part of the larger island. The chalet is a sort of tavern, comprising a small theatre, in which are acted some minor pieces during the summer months.

Lake Superior is divided by a road under which the water passes, as required, through several rocky passages into the deep and sinuous end of the lower lake. The upper lake has a surface of nearly 4 acres; length, 455 yards; mean width, 60 yards; and depth, from 3 to 5 feet. In 1855, 50,000 young salmon and trout artificially hatched were put into the lakes; but most if not all have since died from the want of current. The water for the lakes is taken in part from the Seine, by means of force pumps placed at the Quai de la Conférence, and in part supplied by the artesian well lately opened near the Grille de la Muette, where the water, after rising 1600 or 1700 feet, gives a temperature of 37° or 38° Fahr. The water enters at the Grille de la Muette, and is conducted to the Butte de Montmartre, where it enters the southern extremity of Lake Superior, forming a cascade.

The Butte de Montmartre is an artificial elevation which has been formed with the earth obtained by the excavation of the lakes and rivulets; it is the highest point in the Bois de Boulogne, being from 32 to 40 feet above the surface of the lakes. From here we gain glimpses of the heights of Issy, Meudon, Bellevue, Saint Cloud, Suresnes, and Mont Valerien. The full view of this magnificent and picturesque landscape has been intentionally shut out by clumps of the old wood, which are here rather too artificially arranged. The slope from here to the Porte Boulogne is very bare, the walks so superbly constructed everywhere else being here very diminutive, and the trees are too far from the edges. Even the grass here is coarse and ill kept, and the various beauties of the lakes are indistinctly seen; but these slight defects are very likely soon to be removed, and are well compensated for by about twenty minutes' walk to the grand cascade; and the road we shall select, although a little tedious, is certainly the most interesting. On descending the magnificent walk which follows the lakes, a full view is obtained of the lakes and islands, every step presenting some new beauties. We arrive in a few minutes between the lakes—this chosen spot around which all the luxurious grandeur of the place lies profusely spread. The slopes are here often abrupt, sinuous, and undulated, but covered to the water's brink with a verdant carpet of well-kept grass, planted here and there with clumps of the finest Coniferae, shrubs, and in summer with isolated plants, such as *Aralia papyrifera*, *Caladium esculentum* and *odoratum*, *Ficus elastica*, *Musa rosacea*, *Wigandia urens*, *Gunnera scabra*, *Erythrina*, *Nicotiana wigandioides*, *Bambusa aurea* and *metake* &c.

There are some specimens of *Araucaria imbricata*, *Wellingtonia gigantea*, *Taxodium distichum*, *Daerydium cupressinum*, *Cedrus deodara*, *Abies Douglasii*, and *Abies pinsapo*; but Coniferae do not grow so well here as in England.

There is a small walk forming a kind of edging around the lower lake and its islands, leaving a small margin of grass between it and the water, where stand some fine examples of *Gynerium argenteum*, *Weigela rosea*, *Fraxinus pendula*, *F. ornus*, and *Salix babylonica*, with the beautiful *Daubentonia magnifica*. Among these run numerous walks, leading to bowers, and mounds, and little valleys, now kissing the clear waters where close by grows the Pampas Grass, in the shadow of whose plumes rests leisurely the heron or duck, and again rising gradually to rockwork clad lightly with Ivy. On the water everything is gay and living; thousands of beautiful-feathered birds skim to and fro, prattling their different languages, while the swan, more conscious of his beauty, may be seen arranging his white plumage in the mirror of the water.

On arriving at the northern extremity of the lakes, where the water is on a level with the surrounding banks, but is kept from overflowing by a shallow outlet allowing the surplus to fall gently into the mouth of a rivulet already mentioned, this divides into three—the two minor ones to the right go, one towards the Jardin d'Acclimation, the other towards Madrid; and the third, the longest and most winding, we shall accompany till we arrive at the Grand Cascade of Longchamps, where it tumbles about 20 feet over a large semicircular surface of projecting blocks of half-decomposed limestone, which have been brought here from the Forest of Fontainebleau. Underneath the falls is a cavern, on the roof of which may be seen some examples of fantastic stalactites. This water is received in a large bason which furnishes the numerous little rivulets and lakes which spread over the plains below.

The plains of Longchamps have been purchased by the city, and were annexed to the Bois de Boulogne in 1854; there 200,000 trees and shrubs have been planted in isolated clumps, so as to harmonise with the surrounding landscape. A portion of these plains is set apart as a race-course and for holding reviews. Returning to the summit of the rock, which forms a sort of arch above the water, we behold these verdant plains stretching down to the Seine, while beyond are the hamlets of Suresnes, Saint Cloud, and Neuilly; a little to the left may be seen the old town of Boulogne; while close by to the right, on the main road to Suresnes, may be seen the habitation of the Prefect, standing on the ancient ruins, and close to the tower of the famous Abbey of Longchamps, which was established by Isabelle of France.

Bois de Boulogne is laid out with that rare taste and

judgment which understands how to unite nature with art, without leaving them in disputation as to their respective rights—walks conducting us to shady wilds, or glades opening to receive the bright radiance of the sunshine; vistas terminating in indistinct grandeur; lakes, rivulets, and cascades, either in motion or repose; sunny slopes and happy valleys, the fit homes of contentment and pleasure.—**WILLIAM KELLY.**—(*Irish Farmer's Gazette.*)

### ENTOMOLOGICAL SOCIETY.

THE June meeting of the Entomological Society was held on the 5th inst., F. P. Pascoe, Esq., F.L.S., President, in the chair. An unusual number of new members and associates were elected. Amongst the donations made to the Society since the last meeting were the publications of the Royal and Zoological Societies, and the Entomological Society of France, also a Memoir addressed to the Trustees of the British Museum on the disgraceful state of the entomological collection in the national Museum, in consequence of the insufficiency in the numbers of persons employed in the entomological department, by "Philocosmos;" also a remarkable Memoir by Dr. Sichel, of Paris, on the varieties of *Bombus montanus*, a species of Humble Bee, in which the author considered that a number of species, hitherto regarded as quite distinct, were only local varieties of one inconstant species.

The Rev. Hamlet Clark read a passage on the luminosity of the Firefly in Brazil, quoted by Gosse from Southey's "Madoc," in which the simultaneous emission of the light by great numbers of these insects was recorded. He also read descriptions of twenty-eight new species of plant-eating Beetles from West Australia, sixteen of which belonged to the genus *Paropsis*. He also distributed a number of specimens of a new and remarkable Coleopterous insect, collected by Captain Bowker in British Kaffraria, allied to the genus *Macronychus*, and which was found very numerous in the neighbourhood of the Sunn River, whirling about in the sunshine over the edge of a fall of the river, hovering and making sudden dives through the fallen water, and fastening themselves to the face of the rock.

Letters were read from Mr. Edwin Reed, who is engaged in an entomological excursion in the neighbourhood of Bahia, and from Mr. Brewer at St. Michael's, Azores, who is also engaged in an entomological voyage.

Mr. Smith exhibited a specimen of the very rare Beetle, *Apate capucinus*, taken by his son in Bishop's Wood, Hampstead, running over felled oak timber. The capture of other specimens by the Rev. F. W. Hope, Longmynde Forest, Shropshire; and by Sir T. Pasley, in Pembroke Dockyard, were mentioned.

Mr. F. Bond exhibited a specimen of the rare Moth, *Dianthæcia albimacula*, captured last year, near Gosport, in June; also, a specimen of the fine North American *Bombyx Polyphemus*, reared in this country from the cocoon, of which a very fine large Ichneumon, of the genus *Ophion*, had been reared.

Mr. Stainton exhibited several curious cocoons from Mentone on the banks of the Mediterranean, chiefly found on *Quercus Ilex*.

The President exhibited a species of the genus *Dorcadron*, from Alicante, supposed to be new.

Mr. Moore read a paper containing descriptions of various new species of *Bombycidae* or Silk Moths from India.

Professor Westwood mentioned an interesting mode of preserving caterpillars of exotic *Lepidoptera* by pressure, as exemplified by various specimens in the Burchell collection, recently presented to the University of Oxford.

An animated conversation took place with reference to the meeting recently held at the South Kensington Museum for the disposal of the iron-covered buildings for local museums; when it was generally admitted that it was desirable to establish museums in various parts of the metropolis. The death of M. Leon Dufour, the father of entomology in France, was announced.

A paper by Mr. Smith was read in opposition to the views of Dr. Sichel as to the varieties of *Bombus montanus*; and Professor Westwood made some observations on the prolific powers of workers of the hive Bee recently observed,

and on the vast quantities of female Wasps occurring during the past spring, notwithstanding the destruction of great numbers of Wasp nests last season, by a disease similar to that of "foul brood" in the hive.

### STRAWBERRY LORD CLYDE.

IN Belgian catalogues I notice that, according to Mr. Radclyffe's opinion, the new Strawberry Lord Clyde is the most valuable of all existing kinds. How does it happen that Mr. Radclyffe does not mention this fact in his last article, page 461, of this paper? Or has it, perhaps, come to "nil?"—FRAGARIAN.

### WORK FOR THE WEEK.

#### KITCHEN GARDEN.

THE principal crops here will now require attention in weeding, hoeing, thinning, and watering in dry weather. *Broccoli*, where the Cape varieties have been sown in drills thin them out to one plant at every 2 feet, and immediately afterwards water those left. As soon as the weather will permit plant out the main spring crops. *Carrots*, a little more seed may be sown; to produce a later crop for drawing young. Loosen the earth between the main crops where it is baked hard. *Cauliflowers*, some of the late sowing should be planted as soon as the weather will permit, or if the planting of them can be no longer postponed, they must be watered until they make fresh roots. *Celery*, no culinary vegetable demands larger supplies of water at this season, the first crop runs to seed in a short time if not kept moist, and the late ones will be very much checked for want of it; the earth should be stirred about the plants whenever it appears crusted. *Cucumbers*, the plants on the ridges will be much benefited by being mulched with short grass or litter of any kind, they should be previously watered, which may generally be done early in the morning. *Lettuce*, where the seed has been sown in drills thin the plants to 1 foot apart. *Mushrooms*, this is now a good time to make spawn for winter and spring use; after the bricks are made and partially dried they may be placed in layers in an open shed, with a thin layer of spawn from the old beds which have done bearing between each course; the whole should afterwards be covered with sufficient dung to keep it moist and warm. *Small Salads*, keep up a succession by repeated sowings in the open ground in a shady spot. *Spinach*, it is necessary to sow once a fortnight let the weather be what it may, as it so soon runs to seed. Keep it watered during dry weather. *Tomatoes*, keep them trained to the wall and well supplied with water, or but very little fruit can be expected. Advantage must be taken of the first good shower of rain to get out the main crops of Brussels Sprouts, Broccoli, Savoys, &c.; until then they had better remain where they are. Recently-transplanted plants must be kept constantly watered, and the ground about them occasionally stirred.

#### FRUIT GARDEN.

The season being favourable for growth the necessity is increased for keeping all young wood properly nailed to the walls, in order to guard against the effects of high winds. Gooseberries and Currants trained against north walls should have the leaders nailed in, and all the side shoots spurred down to within a few joints of the base. Peaches, Nectarines, and indeed wall trees in general, will be greatly benefited by occasional strong syringings, whether infested with aphides or not; for besides washing away all cobwebs, &c., which of itself is a benefit, it disturbs and routs out woodlice, earwigs, and other vermin, which are sure to congregate among the shreds and at the back of the shoots, and which, if left undisturbed, will spoil the fruit. Pay particular attention to stopping and tacking-in the shoots of Vines.

#### FLOWER GARDEN.

Attend to staking in due time. Peg down the early Verbenas and Petunias. Reduce occasionally some of the blossoms in the bud state on some of the very free-blooming Perpetual Roses; it will cause them to remain longer in bloom. Let gross shoots on fancy Roses be pinched off, when a few eyes long, after the manner of fruit trees.

## GREENHOUSE AND CONSERVATORY.

These are now gay with Pelargoniums, Fuchsias, Balsams, Cockscombs, Globe Amaranths, and Lilies, intermixed with other gay plants. A slight canvass awning should be employed, and a system of cleanliness maintained. See that there are successions of the above plants and others encouraged and growing-on for maintaining a display throughout the autumn and winter. The time has now arrived that many Heaths and New Holland plants will require more pot room. Give every attention to *Lilium lancifolium*, *Chrysanthemum*, *Salvia splendens*, *Globe Amaranth*, tree *Carnations*, *Scarlet Geraniums*, *Cinerarias*, *Chinese Primroses*, *Gesneras*, *Begonias*, *Euphorbias*, &c. Let them have plenty of pot room, good rich compost, a moist atmosphere, and plenty of space for the perfect development of their foliage. We have nothing that surpasses the *Epacris*, the winter-blooming *Ericas*, and the *Cytisus*, and these should not be overlooked in the crowd of suitable plants. The early-flowering Pelargoniums will now have been out of doors some time, and if the wood is thoroughly ripened, they must be cut-in preparatory to the coming season. Do not spare the knife, and after they are all cut-in place the plants in a shady situation, so that they may break regularly and strongly. Herbaceous *Calceolarias* which have done blooming, should have their flower-stems removed forthwith, and the plants be afterwards placed in a shady situation under the protection of a frame. The atmosphere of plant-houses can hardly be kept too moist at this season, therefore sprinkle every available surface frequently, and syringe growing stock twice a-day during bright weather. Avoid a too free use of shading, and ventilate freely in order to secure compact growth.

## STOVE.

Take particular care to give liberal syringings, and keep up a constant humidity by dashing abundance of water about the floor, walls, &c. This with abundance of air and light shading will maintain a kindly atmosphere. See to the stock of *Gesnera zebrina*; also, provide a sufficient number of plants of *Euphorbia fulgens*, which is one of the most useful of winter-flowering plants both for cutting and furnishing the drawing-room, conservatory, and stove throughout early autumn, winter, and spring, if grown under a good successional system of culture. As plants will soon be ripening their young wood, they want as much light and even moderate sunshine as possible, therefore shading should be then used with great caution. At all times whenever it is, it should be removed when the weather is in any way dull. In the case of *Orchids* this is especially necessary, in order that the young leaves and pseudo-bulbs may be thoroughly matured. Plants in this condition, or nearly so, should be removed forthwith to a cool house, and care taken not to induce them to push again, as a fresh start would interfere with their flowering next year.

## PITS AND FRAMES.

These will require abundance of air and the most careful watering daily. Some of the delicate stock will at times require shading during the middle of the day, especially when unplunged.—W. KEANE.

## DOINGS OF THE LAST WEEK.

## KITCHEN GARDEN.

*Turnip Fly*.—In general we are little troubled with this devastator, but though we cannot see the destroyers, we see their effects so much that we have been obliged to sow thickly under a piece of cloth, and when they had two or three good-sized rough leaves, to transplant some 6 or 9 inches apart, in rows 2 feet apart. For the first time, they or a similar beetle has attacked our *Verbenas*, especially *Purple King*, and as good a deterrent as any is to damp the plants with the syringe and scatter over them a mixture of dry road dust and wood ashes. There are many insects that decamp before a good dusting of road dust.

Mulching, to keep things cool, has been the chief work in this department. Sowed successions of *Onions*, *Lettuces*, &c., for salads, and the main crop of *Endive*. Among a lot of fine *Potatoes* that at first were protected by old sashes in earth-pits, we were sorry to notice some traces of the old disease. We hope we shall see no more of it, but we almost

dread a continued cold rain after such broiling weather. A good rain and warm weather after it would do much good. Have placed little twigs and branches of trees over all our late-planted *Cauliflower*. Large flower-pots are good things for the same purpose, taking them off in the afternoon. Every plant or cutting succeeds all the better if never allowed to feel distress. It is much easier to keep such things right, than to make them right after they have gone wrong.

## FRUIT GARDEN.

Watered *Strawberries* in the afternoon with clear water, as the extreme heat seemed to dry the outside of the fruit so much as to prevent swelling freely. We have had some nice *Keens*, but our chief supply out of doors up to the middle of last week has been *Black Prince*. Those plants that we took up and potted late in spring, and plunged out of doors in a heap of tree leaves, have done good service, when placed in a cold pit under glass, in keeping up a good regular supply.

Went over *Peaches* and *Apricots* on walls, thinning out the fruit, superabundant branches, and fastening what were left close to the walls, and lashing them with the engine in the afternoon to prevent *red spider*. We are sorry to say that some of the *Strawberry* plants out of doors are affected by it, and it is such a pest to spread. Keeping it down and frightening it away are better than destroying it when it boldly takes possession. Dipping plants in sized sulphur water, or even brushing the leaves with a water of soft soap and quinine, are often the quickest and easiest modes of getting rid of the little visitor, that we would all wish to be a little stranger. It is singular in what strange circumstances the spider will manifest itself. In a small *Fig-house* or pit rather densely clothed with foliage, a small cut-in plant of *Linum trigynum* had been left on the floor. We could not discover any insects in the house, but the above plant, standing in such a moist shady position, was even ornamented and festooned with the webs of this *Acarus*. The plant and its embellishments were carefully transferred to quarters where they could do no more harm. For many such things the furnace is the best and cheapest remedy. How often does it happen that the keeping and the attempting to clean a dirty plant, perhaps worth only a few pence, involve the loss of many pounds? Destroying insects when once they have got fairly ahead is alike unprofitable and unsatisfactory. Many a bed of *Cucumbers* has had quantities of tobacco wasted on it, and without avail, when a very little of that material or of quassia water would have made all right if the first insect that appeared had been seen and settled. Stirred up soil in borders of *Peach-house*, and gave a good watering, as the fruit is coming in, and promises to give a long succession. A little air as well as moisture to the soil is enjoyed by the trees. Cut, or removed, or placed aside any leaves shading the fruit, as flavour so much depends on full exposure. In these brightest days, however, to prevent anything like scorching of the points of the *Noblesse*, we syringed on the glass some water slightly whitened, just to break the force of the rays without excluding much light. More air constantly on would have saved such an operation, but the more air would have retarded the swelling, and we wished to get some fruit in.

*Vineries*.—In the house from which we are cutting, we have now removed all plants in pots, so that the air may be drier. In very hot days we threw a little water on the floor and stages; in dull days kept dry. Dryness now, however, greatly helps flavour, though it is rather unfavourable to large-swelled berries, if the dry process is too quickly applied. In thinning the late *vinery*, have as a rule left only one bunch to a shoot, and bushels of bunches have to be cut off. They make nice tarts when young—that is, when smaller than the smallest *Peas*. After the berries attain the size of *Marrow-fat Peas*, it would pretty well require a grocer's supply of sugar to make them palatable. A number of ladies and gentlemen have told us, that one of the greatest luxuries they ever tasted, was a tart made of *Grapes* when not larger than small bird shot, and about one-fourth part of *Gooseberries* just formed, and the remains of the blossom at the end of the berry.

*Melons*.—We have said so much on this fruit, that we would merely state now, that to have good flavour in swelling and ripening fruit, it is advisable to give water to the

roots by means of holes or upright drain-pipes, and yet keep the surface of the soil dry, so as to have a dry atmosphere. It is best when these plants are so treated as never to need any shading, unless for a few days when planted out. We dispensed with covering at night after these hot days, as the coolness, with the soil warm, was refreshing rather than otherwise; but, then, a cool night should be protected against that a check be not given.

#### ORNAMENTAL DEPARTMENT.

Proceeded with rolling, machining, and scything the lawn, and nearly finished planting-out bedding plants. After a time of hard continuous work, we are now having the satisfaction of seeing that we shall master our labour, instead of being mastered by it. When there is a great deal of planting-out, there is a good deal of trouble in not only making a different arrangement from the preceding year, but also in giving a diversified tone to the whole place, so that one border or group shall not appear to be a repetition of another, merely slightly varied. Our own taste would prefer the fine outline of trees and shrubs, instead of a tinge of this bedding-out, as the trees will grow whilst we sleep, and require none of the coddling attention that these bedding plants need, even when they receive the roughest, but systematic, treatment. However, sometimes we are forced to go with, and even head the stream, against our own fancies and inclinations. Two matters may be here alluded to. First, in planting out beds as we have lately done, in the case of Geraniums, Dahlias, &c., the plants are sure to flag in this weather. A little shade would be useful, but then the removing of the shade, whatever it is, when thousands of plants are used involves no small amount of labour. In general, we dispense with the shading on that account. We water just enough to moisten the roots, and most likely repeat the process a second time before the day is over, as we have no notion of the propriety of deluging the soil in such circumstances, whatever the quantity of water at command. Our great safety valve is the syringe or garden engine, generally the latter, as a few fine dewy squirts take in a large part of a bed or border. This is continued the first day, if it is a bright sun, just as soon as the foliage becomes dry. We prevent evaporation from the leaves by skiffing moisture on them to evaporate. The second day they will need the process three or four, or more times, according as the sun is bright. By the third day they generally can hold their heads upright, and want little more care in this way. Such plants raised with less or more of a ball out of beds, generally do better afterwards than plants turned out of pots; but they suffer after this season more at first if the weather is sunny, unless such a plan as the above is resorted to. It involves little labour, where there is much planting going on, as a few strokes of the engine handle scatter the mist like dew on the foliage, and on the surface of the ground, and it again rises among the plants in the state of vapour. Some gentlemen were horrified the other day at seeing the engine so used during a broiling sun, and imagined the plants would be scorched. We never saw one injured by such an application in the open air. Who has not often noticed the refreshing effects of a sunny shower? This refreshing of the foliage is often of more importance than deluging at the roots.

The other remark has allusion to watering bedding plants that are becoming established. Partly from necessity and partly from choice, if our plants stand the sun uninjured we let well alone. We would prefer refreshing the foliage of an evening if we could, especially if, from being cloudy, there was little chance of much dew. If we watered at all we would move the surface as soon as possible afterwards, to keep the moisture in and the heat out. We are sure that deluging with cold hard water, as some do, is often worse than labour lost. A little patience would often do more than the water-bucket. We saw several flower gardens last season where great expense had been incurred so as to lay on a plentiful supply of water, and after a hot day they were generally next to inundated with the hose, but with the exception of Calceolarias we can say without egotism that on the whole Geraniums, &c., were not equal to our own that had scarcely had a drop except what came from the heavens—we mean after they had fairly taken hold. One of our best gardeners told us the other day that his great

command of water he had found was of little benefit to him. If he could have had it warm and soft he thought wonders might have been done. Even then we should not forget that the more moisture we give, the more will cold be produced by the evaporation of the moisture. It is pleasing for some of us to contemplate the advantages of dryness, and good will be done if people will see that the beauty of their flower-beds depends as much on deep stirring at first and surface-stirring afterwards as on continuous drenchings from the water-can or barrel.—R. F.

#### COVENT GARDEN MARKET.—JUNE 24.

Ample supplies of fruit and vegetables come in. Pines are sufficient for the demand; but though Grapes very plentiful, Peaches and Nectarines unusually good, being quite equal to what they generally are in July. Strawberries are a high price in consequence of the short supply, the failure of this crop being very general. New Potatoes are abundant, and of the old there is a very heavy stock on hand, much more than is likely to meet a sale.

#### TRADE CATALOGUE RECEIVED.

James Veitch, Royal Exotic Nursery, King's Road, Chelsea.  
—Catalogue of New and Beautiful Plants for 1865.

#### TO CORRESPONDENTS.

GRAFT OF LABURNUM (*Casper*).—The purple-flowered branch grafted upon your Laburnum is *Cytisus purpureus*. It is a native of Germany.

SELECT PEARLONIOS AND FUCHSIAS (*Tom Tit*).—Lord Clyde, Sanspareil, Street of the Fair, Ardel, Viols, Belle of the Ball. Fuchsias Myrtle Banks, Don Giovanni, Charming.

PIGS TURNING YELLOW AND FALLING (*S. B.*).—We suspect that the roots either get dry at the bottom, or are in stagnant moisture. If not, then lessen the tree's vigour now by ringing, and next season by root-pruning. Take no more of a ring of bark off than will heal over this season—say one-eighth of an inch in principal branches.

LILIU GIGANTEUM NOT FLOWERING (*J. F.*).—Your plant, so far as we can make out, is doing well, the bulbs not being sufficiently large to bloom. Water copiously until October with weak liquid manure at every alternate watering, and then withhold water, so as to thoroughly ripen the bulbs or roots. We think you keep the soil wet during the winter, judging from the plant going so much to offsets. Reduce them in number, and treat those left liberally with water and liquid manure, and a top-dressing of rich compost, which last may be done in spring, removing a portion of the surface soil. Secure a good growth by liberal treatment, and ripen the plants well in autumn, and they will bloom finely, unless, indeed, the border be shaded by creepers or plants, in which case this Lily may grow, but will seldom if ever flower.

LAPAGERIA ROSE COVERED WITH LIVERWORT (*Idem*).—The plant that mats over the soil where your *Lapageria rosea* is growing is *Marchantia polymorpha*, usually called *Liverwort* by gardeners, and is a never-failing evidence of a sodden soil. It may be destroyed by providing more perfect drainage (no plant more needs good drainage than the *Lapageria*), or by (to the water required), and frequently stirring the surface with a piece of wood, removing the surface soil now, and top-dressing with somewhat rough peat.

**DROVING CRICKETS** (*A Regular Subscriber*).—A few months since Mr. Fish wrote as follows:—"A friend of ours has availed that means greatly from crickets. They have pretty well cleared off the young shoots of his Vines; and in some gardens they are becoming a perfect pest. Crickets on the hearth, indeed! it would be well if they stayed there. Much as they like heat, keeping them close and even exposed, will not send them away; if there are other places to which they can betake themselves and be warm. We have noticed two modes successful for keeping them down, if not wholly extirpating them. The first is cutting bread into thin slices, spreading a little butter on the upper surface, and placing the slices in the cracks together, and then breaking them into pieces, and placing these in the driest and warmest places. We have been assured that, when examined by a light at night, not only would the crickets be seen eating the baits, but the lively little insects, when cold, or even exposed, will not send them away, but the sickly and the dying. The other mode was sinking a bell-glass level with the earth, &c. of the bed, and filling the glass nearly full with treacle and water. Whenever the cricket got amongst the treacle he was done for. We also noticed an improvement of this—a small strainer, with the mesh half across the width of the glass, was fastened by a pebble close to the outside. It was then bent repeatedly over the rim of the glass, so as to form a sort of flexible hinge. A little treacle was stuck on the end of the stem. When Mr. Cricket marches along, he gets it, it, his weight brings down the straw, and he is precipitated into the liquid, the straw rising again ready for another adventurer."

**CLEANING OLD BOX EDGINGS** (*M. H.*).—Old box edgings cannot be clipped at a better time than now, as, though you cut them well in, they will soon grow, and will look well all the winter. We have seen Box cut in September that did not recover all the winter. We have seen it cut now in April, and so damaged by frost as to be unsightly all the season. Cut now by all means.

**BOOK (R. B.)**.—Brown's "Forester," published by Messrs. Blackwood.

**NAME OF VINE (A. R.)**.—It is the Clotat, or Parsley-Leaved. It is really a variety of the *Rhododendron*, from which it differs chiefly by having its leaves deeply divided into numerous lobes.

**REGULATING LIL-SHAPED RHODODENDRONS** (*A. H.*).—The most suitable period at which to cut in *Rhododendrons* is at, or a little before, the time when they commence their annual growth. It may be done when the flowers fade, but it is now too late to cut them in so as to have the prospect of a good growth this year, or, if growth were made, the shoots, though not being ripened, would be liable to injury from frost and wind. If the shrubs have a number of shoots at their base, they may now be cut down to these, though it would be better to defer doing so until the flowering season another year.

**ROSE CUTTINGS IN WATER** (*A. D.*).—Though we have not tried this mode of propagation, we should, were we going to do so, use soft water. We would not change the water, but drop in a few pieces of charcoal, keeping the water filled in as it evaporated; and finally we would put the cuttings as soon as a callusity was formed. A window to the south, and without shade, would be the best place. Roses strike so freely from cuttings, inserted in a cold frame from July to October, as to render striking in water recommended, even if practicable, for its novelty only.

**FERNSEEDS FROM SEED—CANTON SEED SOWING** (*Inquirer*).—At the back of the border we should have *Eleocharis* and a little row of them 3 feet apart; and in the next row, 3 feet in front, *Campanula pyramidalis*, *Delphinium formosum* and *Hendersoni*, and *Tritoma avaria*; in the next row, *Cyrtanthus* in varieties, *Potentilla*, *Lytirum roseum superbum*, *Lychnis chalcedoniensis*, and *Digitalis gloxiniflora*; interspersed with *Glaucium gaudensis*; 4th row, 2 feet from the last, the others being 3 feet distant, *Pentstemon*, Sweet William, *Campanula grandiflora*, *Antirrhinum*, Columbine, *Armeria formosa*, French Honestyck, *Statice sinuata*, Rocket, Wallflower, and *Polemoniumeruleum*; 5th row, Finks, *Hieracium Lewsonii*, *Lychnis fulgens*, *Armeria formosa*, *Aquilegia Skinneri*, *Campanula Vidalii*, *Platyodon grandiflorum*, *Lychnis Haageana*, and *Papaver orientale*; 6th row, *Dodecatheon gigantea*, *Lychnis fulgens*, *Gnothera macrocarpa*, *Campanula* in variety, *Anemone coronaria* varieties, *Agrostemma coronaria*, *Adonis autumnalis*, and *Linum flavum*; the last and front row, *Statice Armeria*, *Wahlenbergia grandiflora*, *Gnothera taraxacifolia*, *Iberis saxatilis*, *Gentiana scabra*, *Dianthus deltoideus*, *Saponaria cynoides*, *Polyanthus*, *Primula crotinoides*, *Scutellaria macrantha*, *Statice Fortunii*, *Arctotis repans*, and *Arcticia*. This is not exactly the arrangement and plants we should follow ourselves; but you confine us to those procurable from seed, otherwise we should have named plants which, we think, would answer our purpose, and be as cheap, or cheaper. In the long run, besides you will only want a plant or two of each kind. Now is a good time to sow them. *Carnation* and *Picotee* seed, sown now, will stand the winter in a sheltered border, and the plants will be likely to bloom next year.

**GRAPES GAGE TREES OVERLOADED** (*H. L. Ozon*).—As the fruit hangs like "a mass of Onions," pick the grapes, and the tree will not then be weakened, and those left will be finer than if the crop were not thinned. We know of Greengage trees which were overloaded fifteen years since, and which have never borne again until this year.

**CONSTRUCTING AND ARRANGING A FERNEY** (*Irish Subscriber*).—It would be a pity to make the house 8 feet wide when you wish it 10 feet. We would have it 12 feet wide if we had space, but certainly 10 feet. Sashes 1 foot high in front are unnecessary; they add to the expense, and are no gain, but waste of room, for you can carry the rockwork higher without the front sashes. For so narrow a house we would have a path 3 feet wide along the centre, and rockwork on one or both sides—certainly at the back—carrying it to within about 3 feet from the glass roof; and in front the same kind of rockery only lower, and reaching to 1 foot 6 inches from the front sashes. For the doorway there is nothing to hinder the work at the other. This arrangement might interfere with your proposed mode of heating the contemplated fernery from the greenhouse; but as the heat entering by the three openings would not be sufficient for such Ferns as *Davallia cicutaria*, &c., there is nothing to hinder the path 3 feet wide all round, except at the doorway, wherever it be, and having the pathway in the centre; only you must grow the better kinds of the hardy Ferns, which are equally handsome with those requiring greenhouse or stove protection. We do not have stony walls of the inside of the house, and the spores of Ferns vegetate in them rapidly; but we think only the commoner kinds of Ferns would do this; for the majority of Ferns delight in rock rather than rich decaying vegetable matter. With the walls of turf you might have rockwork in the centre, with a pathway all round. This arrangement would, undoubtedly, look well, only you could have Ferns growing out of the turf wall; and yet we are puzzled to know what becomes of the turf wall when the whole is reduced to mould. We suppose the wall is not so perpendicular, or we should not have the turf in the outer wall, but placed tier above tier, sloping upwards. We have, in the absence of large rockstones, had them placed in the form of a stage, forming steps of turf, and planting the Ferns on the shelves, which appeared as so many terraces, and the "green" of the ferns was seen in the crevices. I presume, something of this kind that you propose, by having which your openings for heat from the greenhouse will be free; but they will not answer, or give sufficient heat, for half-hardy Ferns.

**ROSES (Tyro)**.—Your No. 1, is one of the old unnamed Provence Roses, but I think it is a variety of *Provence No. 1*, which we saw here, the spray of your Rose trees show that the soil requires to be manured, well watered, and the surface mulched.

**CONCRETE WALKS (Amateur)**.—They wear well and bear sweeping. Weeds will not grow well on them, but more than on the asphalt. Trench and gravel should be moderately shallow, put them in dry, and water afterwards. Roll both before and after watering.

**CABBAGE PLANTS DYING** (*Subscriber, Wigton*).—We have no doubt that the grubs which eat the stems of your Cabbage plants underground, are the larvae of the Daddy Longlegs (*Tipula*). The best course to pursue is to have the ground carefully examined by gently spudding it up with a knife round each plant. The grubs will be found close to the stem. A large bed may be thus gone over in a few hours, and every grub destroyed.

**PRIMULA FARINOSA**.—I have been up into the Craven districts collecting wild flowers, and having collected more roots of *Primula farinosa* (*Bird's-eye Primula*), than I need, I offer the surplus to your readers. If any lover of alpine plants, particularly those who live in situations where *Primula farinosa* is not to be had, will send an addressed envelope, or box, with six stamps attached to pay the postage, to Mr. Robt. Smith, Dewsbury, Yorkshire, or to the writer, they will receive them very promptly.

**NAMES OF INSECTS (Mrs. C.)**.—The grubs which destroy your *Gaulthier* plants are not wireworms. They are the larvae of a two-winged fly (very like the house fly), belonging to the genus *Anthomyia*. The young plants affected ought to be covered over with netting or gauze, to prevent flies and burrs. The Rose leaves have been gnawed by the caterpillars of one of the Tortricoides Moths. As they have been quite smashed in the post, it is impossible to determine the species. The injured and rolled-up leaves should be collected carefully and burnt.

**NAME OF ROSE (E. J.)**.—The purple climbing Rose is the Old Boursoisul.

**NAMES OF PLANTS (A. B.)**.—1, *Hyperix Rooperi* (?); 2, *Anchusa italica* 3 and 4, unnameable; 5, *Sollia peruviana*; 6, *Bizia maxima*. (*A. Foenig Gardener*).—1, *Alyssum saxatile*; 2, *Nepeta cataracta*; 3, *Asplenium vitarium*; 4, *Arum liliatum*. (*A. Subscriber*).—*Niphobolus lingua*. (*C. B. Powell*).—*Helipterum eximium*. (*W. Foster Newton*).—*Diervilla japonica*. (*A. Journeyman Gardener, Griff*).—1, *Pinus mugo*; 2, *Abies montana*; 3, *Cryptomeria japonica*; 4, *Fernctya mucronata*; 5, *Senecio sp.*; 6, *Garrya elliptica*; 7, *Menziesia poliflora*; 8, *Helianthemum croceum*; 9, *Alyssum saxatile*; 10, *Valeriana saxatilis*; 11, *Phlox setacea*; 12, *Antennaria plantaginifolia*; 13, *Veronica agrestis*; 14, *Myosotis sylvatica*; 15, *Saxifraga hypnoides*; 16, *Prunella grandiflora*; 17, *Geobus tuberosus*. (*G.*).—Four Ferns were not numbered; they are *Gonolopteris pennigera* and *Cystopteris fragilis*. (*Inquirer*).—1, *Asplenium adiantum-nigrum*; 2, *Nephridium molle*; 3, *Lactaria spinulosa*; 4, *Cystopteris fragilis*; 5 and 6, *Polyctichum angulare*; 7, *Lactaria Filix-mas palencosa*. (*A. K.*).—1, *Erica Baurii*; 2, *Erica*; 3, *Castanea vulgaris*; 2, *Prunus pinatifida*. (*J. G.*).—*Sempervivum tortuosum*. (*A. S. A.*).—*Nepeta Mussinii*. (*Without Name or Initial*).—1, *Polemonium corollatum*; 2, *Geranium sanguineum*; 3, *Saxifraga ajacifolia*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending June 24th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.
	Max.	Min.	Air.		Earth.				
			Max.	Min.	1 ft. deep.	2 ft. deep.			
Sun. 18	30.327	30.261	59	47	63	61½	N.E.	.00	Uniformly overcast and rather cold; overcast at night.
Sun. 19	30.316	30.280	68	32	62	61	N.E.	.0	Densely overcast; fine with hot sun; at freezing at night.
Tues. 20	30.328	30.274	59	30	62	60	N.E.	.00	Very fine; hot and dry; below freezing at night.
Wed. 21	30.296	30.274	59	30	62	60½	S.	.00	Very fine; cloudless; with excessively hot sun, and dry air.
Thurs. 22	30.298	30.125	64	40	63	60	N.E.	.00	Dry haze; hot and dry; fine at night. Fair; cloudy at night.

## POULTRY, BEE, and HOUSEHOLD CHRONICLE.

### AMONG THE CHICKENS:

I HAVE just returned home from a visit of a few days' duration. Whether I have been in Cumberland or Cornwall, Suffolk or Sussex, it matters not; sufficient to say it was a very pleasant visit. I like a visit of a couple of nights: it is not too long nor too short—long enough to see your friends, renew the intercourse, talk over all that has happened since you met, and not so long that you become anxious about those at home, or start with terror at the sudden ringing of a bell at night, and fear a telegram to say, "Baby's got the measles!" when after all it was only that petted tom cat which scratched at the window, and was let in, and struck against the bell hung on the shutter for fear of thieves. Two nights, that is the right length—there is royal warrant for it, for the Queen's guests go for that time. By the way, don't fancy that it was a visit to Her Majesty—that cannot take place under the present Government. "WILTSHIRE RECTOR'S" presence at Windsor would cause serious alarm to the Chancellor of the Exchequer; his grim face might be laughed out of court favour—who knows?

Well, I had my visit and am home again, and that little visit was perfection—pleasant to anticipate, pleasant to enjoy, and pleasant to look back upon. All visits are not so pleasant. Thus, visits to grand houses are often horrible things. When I was younger I was (well, we are all weak when young), overjoyed to receive an invitation from a grand country gentleman who lived in ducal style. I went with great glee—it was weak of me, I own—but I returned with greater—happy, only too happy, to escape home again. That was a miserable visit. The weather was cold, and damp, and dreary. I was put into a little draughty room, opening directly upon the top of a staircase. I could not during the whole morning get into my room to write or read, as the housemaids apparently resided there until noon. Worst of all, there was nothing to do, nowhere to go, no retreat. The drawing-room, of course, was supposed to be inhabited by the ladies; in the music-room they were practising; in the library they were in full force, where one poor male guest dared to be sitting writing his letters, but looked very uncomfortable all the while. I was too shy to stay there; I durst not remain in that room alone with rustling silks—that room usurped (for I hold it was an usurpation), by a bevy of fair dames. Then there was no retreat; as to my own room, to which ever and anon, like a terrified rabbit running to his burrow, I bolted up in the hope that those maids had finished, but there they were, gaunt and weasel-faced—oh! I remember them well—brandishing brooms and rattling dust-pans. I savagely repeated Tennyson's lines slightly altered—

"Bitter housemaids, waiving fast!  
Haste the clothes upon my bed,  
What! the flower of life is past!  
It is long before ye wed."

That was a miserable visit, and I was a wretched guest. What alleviations to my miseries were huge footmen matching like twin elms, or gorgeous furniture, or dazzling plate? I had rather have had a leg of mutton to eat, a deal table, with a five-pound-a-year little maid to wait on me, and the only plate my own, and that willow pattern. I shook my fist at that big mansion when nearly out of sight down the drive—it was a comfort to shake my fist at it, and I said through my clenched teeth, "I'll never enter your door again—no, never!"

But a truce to all unpleasant things. I hold it to be a law with all agreeable guests not to hang heavy upon their host's hands, and especially to get off somewhere during the interval between breakfast and luncheon. "To your room, go?" "Yes, if the housemaid permits," but go somewhere. Well, during my late visit I had somewhere to go, for my host was a poultry-fancier. I went and sat "among the chickens," my felt hat, so light it was scarcely felt, on my head, and my camp stool in hand. Down the garden paths were numerous coops with chickens of various ages coming in and out. I sat me down in the front first of one and then of another coop. N.B.—There was one lot of

black ducklings; I saved the life of a very juvenile one who was lying on his back having nearly his last kick, but my hand saved him from—"kicking the bucket." A man passed me while sitting among the chickens and said, "Nice gardeners them chickens be, sir." I made no answer, so perhaps he thought I agreed in his dislike of the presence of the little things in a garden, but I did not agree with him. One hen had but one chick. "Oh, that cold spring!" thought I. None had large broods. The mother of the one was, of course, the most fussy of all, just as human mammas are; and very capricious and troublesome was that one, just as only sons usually are. Chickens vary in temper. There is the sullen chick; the glutton who runs off with what he cannot swallow. A neighbour's Hamburg cock choked himself in that way. I long to tell the story to all greedy chicks—indeed, it ought to be inserted in every chicken primer. Then there is the persevering chick, who at the peril of breaking his beak will break the hard crust. There is also the good-tempered chick who pecks nobody, and the sharp-tempered who pecks everybody; the cuckoo-like chick who turns another out of the best place, and the poor little chick, feather-light, who runs—skins along, rather—with his wings drooping, the very last to get home, and is so thin that the coop-bars are a world too wide for his lean form. He never will grow up. Well, then, he never will feel the knife run into his jugular artery. "Whom the gods love die young." And if chickens vary in temper, how the same vary in appearance at different ages. At first all are "things of beauty;" Cochins, the little golden fleeces; Black Bantams, scarce chicks, little birds Marten-like; Game with their three stripes, and long, fine, brown, polished noses; Hamburgs, speckled;—lovely little things every one of them. But as with mankind so with chickens.

"Beauty is but a fleeting good;"

for there soon sets in the ugly age when they each and all become ragged wretches. If they have access to a manure-heap, which mine have, they become dirty as well as ragged. They at this age strongly resemble London street boys, with a queer, thievish, sideway, cheating look, ready to gamble for half-pence, or to whine out, "Please toss us a brown, sir." I own I pay little attention to them. I don't think they look respectable company. I had a thought of sending them to the ragged-schools. I exclaim, "Are these the lovely things of three weeks since? What! to this have ye come?" I think of Hamlet in the churchyard scene. I contemplate writing a paraphrase of Juvenal's immortal tenth Satire *more* Pope and Swift, and applying the famous "*Expende Hannibalem*" to — "Oh ye gods!" — to chickens. Or I remember Hervey's "Meditations among the Tombs." I read it years ago at an old lady's, and was frightened by a cut representing a figure divided from top to toe by a straight line, on one side, one half, a lovely lady dressed in the height of the fashion of that day, and very beautiful, too, she was; the other half a grim grinning skeleton. Underneath were the words, "Corinna was one night at a splendid ball, the next," and so on. Such a change, at least almost such a change, takes place in chickens; so evanescent is chicken beauty, but unlike human beauty, save when the sweet-looking matron almost eclipses the slender girl one knew twenty years ago. And this takes me to the field beyond the garden, where the bigger chickens were, and marvellously had they recovered their beauty. They were Cochins every one—some lying down, others peering through the long grass, showing their sensible-looking heads and bright golden hackles; some, the bigger, off for a stroll—no mother's attendance needed by them: oh no! quite strong, and old enough to take care of themselves. How clean and pretty the new-grown feathers look! That large, light-coloured pullet is exquisite in feather, the yellow straw hackle and the creamy back. The hobbledewy cockerels, though ungainly, are not ugly; and as the new fluff blows about on both cockerels and pullets, I perceive their beauty is fast returning—the beauty of a fuller growth, not baby beauty, but the beauty of youth.

I enjoyed greatly my two mornings "among the chickens." I learned that even early in the year a brood reared in a cucumber-frame was entirely lost—not one survived, owing to their not having sufficient ventilation. Cochins do not require warmth, and die if they have heat. I learned how

some improve that did not promise well, and how a tall cockerel became a lanky cock, and that a chicken that carries its tail awry as a chicken will as a hen do just the same.

My last act was to choose a pen of adult Cochins for an exhibition, and by to-day's post the delighted owner tells me that pen has taken first prize. "Well done!" say I. I am sincerely glad, and not a little proud of my judgment. It was not unaided, however. I looked at the pen after we had chosen them when they were in the basket, and pronounced them "beautiful." N.B.—They were not so large as so thoroughly well-shaped. The Judge who awarded the prize had the reverse of a coarse taste.—WILTSHIRE RECTOR.

### THE BEVERLEY EXHIBITION OF POULTRY AND PIGEONS.—JUNE 21st.

For a period of eight years an exhibition of poultry has annually taken place, under the superintendence of a committee of gentlemen connected with Beverley, and year by year its improvement has become more and more apparent, until it holds place among the best of the poultry shows in the United Kingdom. By one of those most singular coincidences that so rarely happen, the entries of last year, and those of the Show just held, tallied as to numbers to a pen; but it must be borne in mind, that the Exhibition of this year, as a whole, infinitely surpassed in quality any of those preceding it. That public interest and public confidence in the Beverley Show are thus strongly manifested has no doubt arisen from the rigid punctuality always displayed in the careful repacking and speedy return of the specimens the instant the meeting has closed for public inspection. Invariably by the very first train leaving Beverley on the morning following the exhibition, every pen has been ready and awaiting dispatch at the railway station, and, consequently, all grumblings and disappointments have been done away with altogether, as to the return of the birds exhibited, for, on the contrary, such firm confidence has been established, that year after year this Exhibition has increased in popularity, until it now embraces contributions from nearly every noted yard in the kingdom. Another most favourable feature is the fact that the birds are exhibited only a single day, and, therefore, very little (if any) falling off in condition can ensue from their very brief confinement. It is barely necessary to name, that the attention paid to the welfare of the birds during the Show, is also of the highest character, and that the Norwood Assembly Rooms, as to construction, are perfect both as regards light and ventilation, also for the purposes of a poultry show.

The *Game* class for a cock and one hen headed the Beverley list, open to all colours; and, as the sequel proved, in such competition Brown Reds had a decided advantage. Of this variety of colour there were several extraordinarily good pens shown, and the competition was necessarily severe. Mr. Matthew, of Stowmarket, took the first place, closely pressed by excellent pens, exhibited respectively by Messrs. Boyes and Julian, both of Beverley. Another good pen was shown in this class of the same colour, but the hen being "duck-footed," or, as is commonly called in this district, "duck-heeled," it was impossible to hold place in any competition, that being always a fatal defect. In "Single Game Cocks" (of any colour), Brown Reds again carried the day throughout the whole prize list, the prizes falling to Mr. Julian, of Hull; Sir St. George Gore, Bart., of Hopton Hall; and Mr. Matthew, of Stowmarket. In point of first-class condition, the *Game* birds of this year's Show were evidently scarcely equal to those of previous years. The *Spanish* class was undoubtedly, perhaps, one of the finest ever placed before the public, a fact pretty well illustrated from the circumstance, that twelve pens out of an entry of only sixteen, received favourable notice on the prize list. Mr. Beldon, it will be seen, took first and third; and Mr. Rodbard the second premiums. Few birds exhibit at this time of year to greater disadvantage than *Grey Dorkings*; many of the pens were, doubtless, beyond the usual merit of even prize birds; but still want of condition was manifest throughout most of them. The class for *Cochins* was open to every colour, and a marvellous competition ensued; the truth being, it was the class of all others causing most public attraction in the Show. Captain Heaton, of Manchester, here took first prize,

with a most excellently well-shown pen of Buffs; and second with Silver Cinnamons; Mr. Zurhorst, of Belle Ville, Dublin, being successful with a pen of unusually good White ones for third position. Our readers will, by referring to the prize list, find that not less than ten pens from the best breeders of Cochins in the kingdom, also were "highly commended," besides four pens one step lower in the scale. The competition was very severe. Although excellent otherwise, we were sorry to see a pen or two of Cochins of good natural merit, had their tails purposely broken down and otherwise tampered with, such practices being quite inadmissible. Every exhibitor of *Hamburghs* knows from experience, that to show *Hamburghs* at midsummer is one of the most precarious adventures in poultry exhibiting. At this season the plumage of these birds suddenly fades away, and specimens that might be first-rate only a few days previously, go out of character so much as to defy even their identity. Condition in these classes could, therefore, be hardly expected, but it is certain these classes, nevertheless, contained very many pens that a couple of months to come will be no mean rivals, and, indeed, uncommonly difficult to beat anywhere. The *Polish* class was a very superior one, every variety being well shown. Silver-spangled ones carried the day, and Blacks were second. Every pen in the *Polish* class was well shown. The class for "Any other variety," was a strong one and far exceeded this class at our general shows. A pen of the now rarely seen *Ptarmigans* were first, and a pen of *Brahmas* second prize. The *Black Hamburghs*, of which there were four pens shown in this class, are also worthy of especial mention. In the *Game Bantam* class, the time of year now so closely drawing on moulting time, told unfavourably, many first-rate specimens now shown being in a condition quite inopportune for exhibition, still the bulk were good birds, Brown Reds taking precedence, and a good pen of *Black Reds* the second position. In the class for "All other varieties of Bantams except *Game*," a beautiful pen of *Cochin Bantams* was first; and a pen of excellent *Golden-laced Sebright Bantams* second, to the absolute exclusion of many other varieties of great merit—viz., *Black* ones, *White-booted Bantams*, and *White* ones also, the prizes being confined to two, a first and second only.

That Mrs. Seamons, of Aylesbury, should monopolise both of the *Aylesbury Duck* prizes at Beverley, proves that lady courts rather than dreads competition. After so long a journey the manner in which they were shown reflects great credit on her management. The *Rouen Ducks* proved not nearly so deserving a class, but the extra *Duck* class contained *Black East Indians*, the property of Mr. Jessop, of Hull, some very good domesticated *Wild Ducks*, shown by the same gentleman, and some deserving specimens of *Carolina*, and also *Grey Call Ducks*.

The *Pigeon* show was an excellent one, and proved highly attractive, and the classes for *Canaries*, and other small birds did not lack admirers. Mr. Yardley won the silver medal given to the most successful exhibitor of Pigeons.

As in former years, the grounds of Charles Reynard, Esq., were freely thrown open for the purposes of a flower show, and thus the combination of sightseers was this year even beyond the average, as to both gaiety and numbers, for both portions of the meeting were excellently attended. There was a brilliant display of fireworks, and a large assembly of visitors in Mr. Reynard's ground during the evening.

The weather proved most satisfactory, being perfectly fine and free from rain, yet of a temperature so subdued, as to render the flower tent comfortable to the company generally. In bright sunshine the result might have been far less satisfactory, as the experience of the previous day fully attested. We congratulate the Beverley Committee on the success of their show, a result they fully deserved.

**GAME.**—First, S. Matthew, Chilton Hall, Stowmarket, Suffolk (Brown Reds).—Second, W. Boyes, Beverley. Third, E. M. Julian, Hull. Commended, Easton & Mabon, Jedburgh, N.B. (Duckwing).

**GAME COCK.**—First, H. M. Julian, Hull. Second, Sir St. G. Gore Bart. Hopton Hall. Third, S. Matthew Chilton Hall. Highly Commended, W. Bourne, Newton Heath, Manchester; W. Boyes, Beverley. Commended, Sir St. G. Gore, Bart.

**SPANISH.**—First and Third, H. Beldon, Gortstock, Bingley, York. Second, J. R. Rodbard, Wrington, Bristol. Highly Commended, G. Wallace, Aberdeen; W. Massey, Fulford, York; E. Brown, St. Phillip's Road, Sheffield. Commended, S. Robson, Brotherton; E. Jones, Clifton, Bristol; R. Teebay, Fullwood, Preston; Capt. Heaton, Lower Broughton; Burch and Boulter, Sheffield.

**DORRING.**—First, Rev. J. F. Newton, Kirby-in-Cleveland. Second, J. White, Warlaby, Northallerton. Third, Miss A. Charter, Driffeld. Highly Commended, Sir St. G. Gore, Bart. Hopton Hall.

**COCHIN.**—First and Second, Capt. Heaton, Lower Broughton, Manchester. Third, F. W. Zurharst, Belville, Donnybrook, Dublin. Highly Commended, T. Stretch, Ormskirk; H. Beldon, Bingley; C. W. Brierley, Middleton; H. Tomlinson, Balsal Heath Road, Birmingham; W. Dawson, Hopton, Mirfield; T. Boucher, Birmingham; E. Smith, Middleton; W. Harvey, Sheffield. Commended, R. Adams, Birmingham; C. W. Brierley, Middleton, Manchester; H. Merkin, Driffeld; R. White, Broom Hall Park, Sheffield.

**HAMBURGH (Golden-pencilled).**—First, S. Smith, Northwram, Halifax. Second, Birch & Boulter, Sheffield. Highly Commended, Sir St. G. Gore, Bart. Hopton Hall. Commended, H. Beldon, Bingley; H. Snowden, Great Horton; J. Preston, Allerton, Bradford; S. Smith, Northwram, Halifax.

**HAMBURGH (Silver-pencilled).**—First, H. Beldon, Bingley. Second, H. Snowden, Great Horton. Highly Commended, Sir St.-G. Gore, Bart. Hopton Hall; W. Harvey, Sheffield. Commended, A. K. Wood, Burnside, Kendal.

**HAMBURGH (Golden-spangled).**—First, J. Newton, Siladen, Leeds. Second, W. Driver, Bank House, Keithey. Highly Commended, A. K. Wood, Burnside, Kendal; Sir St. G. Gore, Bart., Hopton Hall; Messrs. Burch and Boulter, Sheffield.

**HAMBURGH (Silver-spangled).**—First, H. Beldon. Second, Sir St. G. Gore, Bart. Commended, A. K. Wood, Burnside, Kendal.

**POLISH.**—First, C. W. Brierley, Middleton. Second, H. Carter, Upperthong. Highly Commended, H. Beldon. Commended, H. Beldon; J. Heath, Nantwich.

**ANY OTHER VARIETY OR FARM-YARD CROSS.**—First, R. Loft, Woodmansey (Sultans). Second, Mrs. Seamons, Hartwell, Aylesbury (Brahmas). Commended, J. Wood, Chorley (Brahmas); M. Oliver, Darlington (Black Hamburgs); H. Beldon, Bingley (Brahmas and Black Hamburgs); W. Harvey, Sheffield (Brahmas).

**BANTAMS (Game).**—First, D. Ashworth, Halifax. Second, J. Ward, Chesterfield. Highly Commended, R. Smith, Hull; C. W. Brierley, Middleton; J. Pickering, Driffeld; G. Osgerby, Highgate, Beverley. Commended, R. Tate, Leeds; G. Manning, Springfield, Essex.

**BANTAM (any other variety).**—First, T. Boucher, Birmingham (Buff Cochins). Second, C. W. Brierley, Middleton. Highly Commended, H. Beldon, Bingley (Laced); W. Harvey, Sheffield (White Booted Bantams). Commended, Sir St. G. Gore, Bart.

**GAME BANTAM COCK.**—First, Sir St. G. Gore, Bart. Second, R. Smith, Hull. Highly Commended, Master C. Crossland, Wakefield. Commended, T. C. Harrison, Hull; C. W. Brierley, Middleton.

**DUCKS (Aylesbury).**—First and Second, Mrs. Seamons, Hartwell, Aylesbury. Commended, O. A. Young, Driffeld.

**DUCKS (Rouen).**—First, A. Cattley, York. Second, H. Beldon, Bingley.

**DUCKS (any other variety).**—First and Second, J. R. Jessop, Hull (Black East India and Wild Ducks). Highly Commended, T. C. Harrison, Hull (Brown Call); A. Cattley, York.

#### PIGEONS.

**POWTER COCK.**—First, J. Smith, Walkley, Sheffield. Second, H. Yardley, Birmingham. Third, W. Watson, Beverley. Very Highly Commended, W. Harvey, Sheffield. Highly Commended, E. E. M. Roys, Ashby-de-la-Zouch; C. Cole, Bradford; H. Yardley, Commended, S. Robson, Brotherton; C. Cole. *Hen.*—First and Third, C. Cole. Second and Highly Commended, E. E. M. Roys.

**CARRIER COCK.**—First, H. Yardley. Second, W. Massey, York. Third, C. Cole. Highly Commended, E. E. M. Roys; J. Firth, jun., Dewsbury; E. Brown, Sheffield. Commended, H. Yardley. *Hen.*—First, C. Cole. Second, H. Yardley. Third, W. Massey. Highly Commended, E. E. M. Roys; H. Yardley.

**ALMOND OR KITES.**—First, H. Yardley. Second, C. Cole. Third, J. Smith, Walkley. Highly Commended, W. Watson, Beverley; E. Brown, Sheffield. Commended, C. Lythe, Cottingham.

**TUMBLERS (Any other variety).**—First, H. Yardley. Second, J. Smith, Walkley (Black Mottled). Third, E. E. M. Roys (Black Mottled). Highly Commended, J. R. Jessop, Hull (Mottled). Commended, C. Cole.

**TRUMPETERS.**—First, A. Middleton, Newport. Second, E. E. M. Roys. Third, H. Yardley. Highly Commended, J. R. Jessop, Hull.

**BARDS.**—First, W. B. Van Haansbergen, Newcastle-on-Tyne. Second, H. Yardley. Third, E. Brown, Sheffield. Highly Commended, J. Firth; C. Cole; H. Yardley; W. B. Van Haansbergen.

**FANTAILS.**—First, W. B. Van Haansbergen. Second, T. Ellerington, Woodmansey. Third, T. C. Taylor, Middlesborough. Highly Commended, J. R. Jessop. Commended, H. Yardley.

**JACOBI.**—First and Second, T. Ellerington, Woodmansey. Highly Commended, E. E. M. Roys.

**TURBITS.**—First, J. R. Jessop. Second and Third, H. Yardley. Very Highly Commended, W. B. Van Haansbergen. Highly Commended, E. E. M. Roys; W. Harvey, Sheffield; W. B. Van Haansbergen.

**NUSS.**—First, J. Pickering, Driffeld. Second, E. Leason, Driffeld. Third, A. Middleton, Newport. Commended, W. Harvey, Sheffield.

**OWLS.**—First, Third, and Highly Commended, E. E. M. Roys. Second, H. Yardley. Commended, J. R. Jessop.

**DRAGONS.**—First, W. Watson, Beverley. Second, H. Yardley. Third, T. Statters, Hull. Very Highly Commended, H. Yardley. Highly Commended, W. Massey; C. Cole; H. Yardley.

**ANY OTHER VARIETY.**—First, H. Yardley. Second, W. B. Van Haansbergen. Third and Very Highly Commended, E. E. M. Roys. Highly Commended, J. R. Jessop; T. Statters, Hull; H. Yardley; W. B. Van Haansbergen.

**SELLING CLASS.**—First, T. Ellerington (Fantails). Second, E. Leason. Third, W. Massey. Highly Commended, W. Massey; W. Watson.

#### CANARIES.

**BELGIAN (Cock or Hen).**—First, J. Campay, Beverley. Second, W. Campey, Beverley. Highly Commended, G. Grant, Beverley. Commended, C. Powell, Beverley.

**MARKED (Cock or Hen).**—First, J. Tebb, Beverley. Second, R. Jameson, Beverley. Highly Commended, Miss Campey, Beverley; Mrs. W. Pottage, Beverley; W. Coates, Beverley.

**ANY OTHER VARIETY.**—First, G. Grant, Beverley. Second, J. Campay, Beverley. Highly Commended, Miss J. A. McCoy, Beverley; Mrs. W. B. Taylor, Beverley.

**NEST OF YOUNG CANARIES (Clear).**—First, J. Kely, Beverley. Second, F. Tritschler, Beverley. Highly Commended, J. Kely; if this nest had consisted of three birds instead of two they must have been first.

**NEST OF YOUNG CANARIES (Marked).**—First, W. B. Taylor, Beverley. Second, Mrs. Thornton, Beverley. Highly Commended, E. Campey, Beverley.

**BEST MULE.**—First, W. Campey, Beverley. Second, J. Widdall, Beverley. Highly Commended, Mrs. J. Dale, Norwood.

**BEST REDCAP.**—First, Mrs. Campey, Beverley. Second, R. Dawson, Beverley.

**EXTRA STOCK** consisted of three Australian Parakeets, Very Highly Commended; six Java Sparrows, Commended; and a pair of Bramblings.

The Poultry was judged by Edward Hewitt, Esq., of Sparkbrook, near Birmingham; and the Pigeons by Wm. Boulton, Esq., of Beverley; whilst the premiums for the Singing Birds were awarded by these gentlemen conjointly.

#### WARNING TO POULTRY PURCHASERS.

ALLOW me to put purchasers of poultry on their guard against what I consider extremely like swindling. Some time ago I noticed an advertisement in your paper of Spanish fowls, &c., intending purchasers to apply to certain initials at the post-office, Bayswater, London. I applied and received a reply, with card enclosed, purporting to be from Mr. — surgeon, 4, Queen's Road, Bayswater, London, stating price and particulars, and requesting a post-office order, on the receipt of which the fowls should be sent off. Unfortunately placing reliance on the apparent genuineness of the affair, I sent off a post-office order, which was acknowledged; and in a few days afterwards, instead of the fowls, I received a letter stating that they had been stolen on the night before they were to have been sent off; but that, unless they could be found in the course of a few days, the money would, of course, be returned. I waited some time, and when next I wrote had my letter returned through the dead letter office with the remark on the back "Returned from the post-office, 4, Queen's Road, Bayswater, W., address not known." I suppose I have seen the last of my post-office order.—A VICTIM.

[This is a new and very artful mode of swindling. The swindler in this instance made use of the name of a gentleman of high respectability resident at Bayswater, but with an address different from his, so that if any persons inquired as to the respectability of the alleged vendor they might be misled to believe that he was really the vendor, but had changed his residence.]

#### BUCKINGHAMSHIRE DUCKERS.

DUCKERS are a class of persons resident within ten miles of Aylesbury, whose chief, if not only employment is to furnish ducklings for the London market. They may be divided into two classes—those who keep Ducks solely to furnish eggs, and those who rear ducklings from those eggs. There are individuals in the former class who keep 5000 head, and in the latter, who despatch 2000 ducklings to London every season between February and October.

In Ireland the pig is allowed free entrance to his master's cabin, and the warmest place at the hearth, because he pays the rent, and enjoy the same privilege. On account of the filth so engendered (and I know one small hamlet of twenty houses inhabited by duckers, wherein eighteen persons died of cholera in 1849), many landlords refuse to allow their tenants to keep Ducks. If they do not object, the village board of health have rare work with the duckers; and if the cottages are kept clean, the duckers usually contrive to be summoned before the magistrates for defiling running streams.

When Christmas has turned, and the Ducks begin to lay, the duckers look out for a brooding hen. Poultry books tell you, that you should never sell good brood hens. The duckers know better. When a brood is raised, the foster-mother is sold, because her keep in the interim would cost more than the purchase of another when wanted.

Under the advice of my Mentor, I laid out one shilling in the purchase of a hen, who might from her venerable appearance have laid eggs for the breakfast of the Red Fisherman, when

"He fished in the ark with Noah and Shem."

The pedigree was doubtful, as she exhibited the distinctive ugliness of every known species of fowl. She might be "a run one to look at, but she was a good one to go." She brought out one brood of Ducks, one clutch of Guinea fowl, and one hatch of chickens in the year, besides laying eggs in the intervals of business. Duckers always buy a steady old Dame Partlett, who has been used to the line. They allow themselves to be handled with impunity, and sit closely when young hens are giddy, and break the eggs. When the hen is bought at a price varying from five shillings at Christmas, to half-a-crown in June, she is taken home, and deposited on her future nest under an inverted basket, whilst the ducker goes to purchase the necessary eggs. Their price is usually the same with that of the hen under which they are to be put. Duckers never answer advertisements in the paper, and part with a golden portrait of Her Majesty for a sitting of eggs. The nest is made by putting straw on the ground, on which is placed a piece of damp sacking to receive the eggs. Duckers say that if the eggs are dry, the ducklings cannot chip out; therefore during the period of incubation the eggs are sprinkled daily with cold or lukewarm water whenever the hen gets off to feed. When the eggs are duly deposited, the hen is placed on them, and covered as before. All the eggs are warranted to quicken, so on the third day they are individually examined by the light of a candle. Those which have not quickened are re-couped by the vendor, and the fresh eggs carefully placed with the others. The basket is then removed, because the hen is by that time habituated to her nest, which she will not leave more than once a-day for the purpose of feeding and dusting herself. The eggs require the heat of the hen for about thirty days, and on the day before that she feels them to be coming out, she will not leave the nest even to feed.

When the ducklings are hatched, they are removed from the nest and placed in flannel by the fire. Poultry books recommend peppercorns to be forced down their throats, which is as natural and sensible a practice as that adopted by those nurses who take great care that the infant should make its first extraneous meal off an oyster, or the brain of a hare. That is a fact, and I have often been disturbed at dinner by an applicant requesting the latter delicacy upon the ground aforesaid.

The ducklings never see their foster-mother after they are removed from her, through fear that she might kill them by treading on them. She is forthwith sold, and for about a week they are fed in the house upon bread crumbs and chopped egg. At the end of that time they are taken out of doors, and placed two or three broods together in a pen under cover, whence they emerge once a-day to bathe themselves. If let out oftener, they walk the fat off.

It takes about eight weeks to fatten them ready for market. If kept longer, they become stubby, as their wing feathers are developed and they fetch a lower price. Their food is barley meal mixed with brewers' grains, pollard, and greaves. Chopped lettuce and young onions are given when practicable. A bullock's liver when unfit for market, a dropped calf or disensed cow is a *bonne bouche*, to which but few Ducks attain, although it brings them on rapidly.

The success of the ducker depends on the goodness of the eggs. He can generally rear those which come out of the shell, unless the fever intervenes and carries off all his stock. When saleable they are despatched on Mondays or Fridays to a salesman in Newgate Market, who next week returns an invoice, with a P. O. for the amount. The earliest Ducks fetch 7s. 6d. a-piece. In August they realise 2s. 6d., after which they cease to be sent. This branch of industry supports hundreds of persons, and assists thousands in procuring those articles which their wages would not furnish. Depend upon it, the duckers know their own business best, and that it is more profitable for them to rear ducklings as above-mentioned during the season than to be bothered with hens during all the year.—(Once a Week.)

#### SPONTANEOUS UNION OF SWARMS.

PERMIT me to join you in expressing a hope that Mr. Stuttle will tell us something more about his hive of bees with three swarms in it. For his information I will repeat

what occurred in this neighbourhood from the amalgamation of two first swarms. In a fine May, some years ago, a man had two hives, which swarmed at the same time and settled on the same bush. He, chancing to have a very large hive, shook them into it. The season was a remarkably fine one, and in eight days from the time of swarming the combs gave way and broke down with the weight of the honey, destroying thousands of bees, and the man was compelled to drive the remainder into an empty hive; but from the full one he took 60 lbs. of run clear honey, all collected in little more than a week!

If Mr. Stuttle's hive is so full as he describes it I would recommend him to raise it at least a foot, and see how long in this fine weather his three swarms will be in filling it.—T. G.

#### PREVENTING EXCESSIVE SWARMING, &c.

AFTER a long silence I am tempted to make a few notes upon sundry apiarian matters which have come under discussion in your pages of late, and I will begin with the subject which heads this paper. I quite agree with the remarks of the Editor (May 30, page 423), as to the inutility of destroying the queens of swarms with a view to prevent swarming; at the same time it is very vexatious to see a fine stock throw off swarm after swarm, some of which may be lost, and most of them be worthless, not to speak of the impoverishment of the stock itself. The tendency of my own bees to swarm excessively this year has set my invention at work, and I suggest for imitation the very simple plan, which I have successfully adopted, of putting the swarm in the stock's place. Here, of course, is no prevention of swarming, but it does prevent all "excessive" swarming. I would, in fact, advise the apiarian to be beforehand with his bees, and to make them swarm artificially by driving as soon as he is aware of the existence of sealed royal cells in his hives, otherwise he may chance to lose his swarms. Sometimes you cannot prevent swarming.

"B. B.'s" Dilemma.—The above remarks lead me to notice the case of "B. B.," with whom I can sympathise, having myself lately experienced a similar dilemma. In my own case the queen of the swarm, which took possession of a hollow tree, was a pure Italian of my own rearing. I did not allow "the errant swarm to remain in the domicile it had chosen until the autumn." The tree (a quarter of a mile off) was first carefully examined, then pieces of the wood were sawn off till the cavity was fully exposed to view. In two of the pieces sawn off large clusters of bees were found and brought home, but, the queen not being among them, they were soon all off again. Not to be baffled, I proceeded myself to the tree and smoked them out early the following morning. A bee-dress and gloves, a common hive, and an unlimited supply of matches and brown paper, soon enabled me to bring off my valuable queen and swarm. Holding the hive in such a manner that the bees could pass uninterruptedly from the tree into it, I put the brown paper into the cavity under the bees, and soon had the pleasure of seeing the queen and her subjects march up. In due time the hive was enveloped in a cloth, and carried away. To make sure of her I put her in a new box in my bee-house, in place of the old stock, where she is doing wonders in a very contented spirit.

Hiving of Natural Swarms.—This I prefer doing in the way indicated at page 439, first into a common straw hive, and then into the permanent box; but I find it better to transfer them at once, or as soon as possible, not waiting till evening. I like all these operations to be done in broad daylight, when the bees are active and expectant of locomotion.—B. & W.

#### BEEES PERSISTING IN SWARMING.

ABOUT a week ago all my bees were in a state of great commotion. They are in a south aspect at the bottom of the kitchen garden fully exposed to the sun. I had previously obtained two swarms from the same number of stocks, and had placed a bee-glass over one of the hives to prevent its swarming again, and a piece of comb inside as a guide; but they neglected that, and began building from the bottom. However, they seemed all right and very busy;

but after their commotion a swarm issued again from each hive, and now they have quite deserted the bee-glass, and to-day seem likely to swarm again.—RECTOR, Kent.

[We fear you must now accept the swarms, and forego the attempt to obtain honey this season by supering your old stock; but the glasses may yet be filled if you transfer them at once to the two first swarms.]

### BEES AFTER SWARMING.

ABOUT four weeks since there issued from a plain straw hive of mine a very heavy swarm. For some days previously, not only did the bees hang in clusters about the entrance, but they almost entirely filled a Taylor's super placed over the hive. After the swarm had left the super became empty, though it appeared that while crowded together in the super the bees had contrived to continue the comb through the aperture at the top of the hive, some 5 inches upwards, into the super. There was honey in some of the newly-constructed cells, but the bees must either have consumed it or taken it away to store the main hive, for it soon disappeared.

Now, the drones which previously to the swarm issuing bore but a moderate proportion to the working bees in number, have become relatively so numerous, that during the few hours that the drones take the air they seem to be about one to three of the workers, and I can discern no progress whatever, so far, certainly, as the super is concerned.—C. H. H.

[What you describe is exactly the normal state of things after the issue of a swarm. The super is not likely to be again occupied in force this season, and one or two more swarms may probably issue, whilst the drones will have their fling until the juvenile monarch of the old stock commences egg-laying. Soon after this event takes place, these idlers will have notice to quit, such notice being speedily followed up by a summary process of ejection on the first unfavourable change of weather, or possibly even earlier.]

### VARIOUS QUERIES.

1st. WHAT is the best way and time to change a hive of bees from an old hive to a new one?

2nd. Is it wrong to put the bee-glasses on a new hive and fresh swarm (this year's) before the bees fill the under part of the hive with combs and honey?

3rd. How should the glass be prepared for the bees? Should there be a cross stick as well as an upright one, and is there any fixture to be put on the top of the glass to give the bees air?—A SUBSCRIBER.

[Your hive should swarm at least twice in such a season as this. Three weeks after the issue of the first drive all the remaining bees out of the old hive, and unite them to the second swarm. The contents of the original hive may then be appropriated, and will be found free from brood.

There is no objection whatever to putting a moderate-sized super on a swarm, and it is best done before the stock hive is quite filled with combs.

Glasses should be furnished with some pieces of clean worker comb, and an upright and such cross sticks may be used as are necessary to support them, taking care that those props are as little visible as possible. No contrivance is necessary for ventilation at the top of the glass.]

### THE LIGURIAN BEE AND THE VINEYARDS.

I HAVE been asked to confute a very absurd paragraph under the above heading, which has been copied from a Melbourne paper into several of our English newspapers, and which declares that much damage has been done to the vineyards in Australia by the new bee. I need only state that no complaint of the kind appears ever to have been made in Italy, where this bee is indigenous, nor has it arisen in the Rhine provinces of Germany, into which the Ligurians have been extensively introduced, whilst nothing

that would in the slightest degree tend to give even a colour to the imputation has ever come under the observation of—A DEVONSHIRE BEE-KEEPER.

### SHEEP DYING AFTER SHEARING.

WHAT is it that sometimes causes sheep to die after shearing? I had my little flock of twenty sheep and thirty lambs shorn last week. On going out to look at them in the evening one ewe looked ill, and I asked the man who has charge of them what was the matter. He said one sheep with two good lambs had been looking very ill after being shorn. They had bled her in two places and given her castor oil. I directly ordered gruel with gin in it, but before it could be given the poor animal died. Three men sheared the sheep and lambs, they began at half-past three o'clock and had finished soon after six. Do you not think the sheep must have been injured by the haste and roughness used? This is a matter of some consequence to many of your clerical country readers.—E. R.

[We incline to the opinion that your sheep died from exposure to the great cold which characterised the nights at the time they were shorn. If you do not live in a southern district, you had better have waited until July before you had them clipped. Bleeding and castor oil hastened the catastrophe, if the sheep were ill from exposure to the cold. The men, if expert, did not work too fast. A good clipper will shear from fifteen to twenty and even more sheep in a day.]

### OUR LETTER BOX.

COMPLAINTS AGAINST THE DECISIONS OF JUDGES.—These complaints are always steps in the wrong direction. We are aware that it is difficult to submit with dignity to defeat, but silence under the reverse is by far the wisest course. It so happens that the complaints we have recently received we know to be groundless, for good judges in no way connected with those who gave the awards approved of the awards appealed against. Some of the complainers have had the bad taste to abuse the judges in their absence, and to write to them very ill-advisedly. And to them, and indeed to all exhibitors, we say, if you cannot lose with good temper never send a pen of fowls to an exhibition. We refrain from mentioning names, and will conclude by saying that unless evidence is placed before us that an award has been founded on dishonourable motives we never will assail it.

ROUPEY FOWL (*M. A., Walthamstow*).—Give it one grain of powdered sulphate of copper mixed in a little soft food daily. Feed on oatmeal moistened with ale. Allow it to have as much green food as it will eat. Separate it from all the other fowls. If not better in a week kill it.

POLE PIGEON-HOUSE (*F. T. H.*).—Any carpenter could make you one. If you prefer one ready made you had better advertise, stating size, &c., that you require.

FOOD FOR YOUNG BULLFINCHES (*Matilda*).—Egg boiled hard, and chopped fine, shell and all, with a little crumb of stale bread crumbled small, and a sprinkle of mawseed. Use for your melons, &c., the water which has been placed in the sun.

BOOK ABOUT POULTRY (*Inquirer*).—A very copious and fully illustrated work on poultry will be published at our office in the course of a few weeks. No book that we know treats of capons, nor would we quote it if we did. Caponising is a barbarous and totally needless operation.

BACK NUMBER (*A. T., Noirmant*).—Upon the receipt of four postage stamps with your directions, No. 161 will be forwarded to you by post.

CHARGE FOR GRAZING (*Cecrops*).—All depends upon the abundance of the herbage, supply of water, and other circumstances of which we have no knowledge. You had better consult some farmer in your neighbourhood; no one at a distance can advise you reliably.

BUILDING COW-HOUSE (*W. B. A.*).—It is quite impossible to answer such queries. You had better state to one or two carpenters in your neighbourhood, or elsewhere, the accommodation you require in the cow-house, &c., and then obtain an estimate. In No. 2 of "Fullarton's Home and Foreign Agricultural Miscellany," just published, there are full particulars relative to cow-houses. Any of the hothouse builders near London will send you an estimate; we cannot recommend one in particular.

EARWIGS (*G. C.*).—We fear you have no remedy but to kill them whenever you see them. You perhaps, are not aware that they fly.

BEES DECREASING (*L. D.*).—There can be little doubt that the dwindling stock has lost its queen. The readiest mode of restoring it to prosperity would be by adding to it a small swarm.

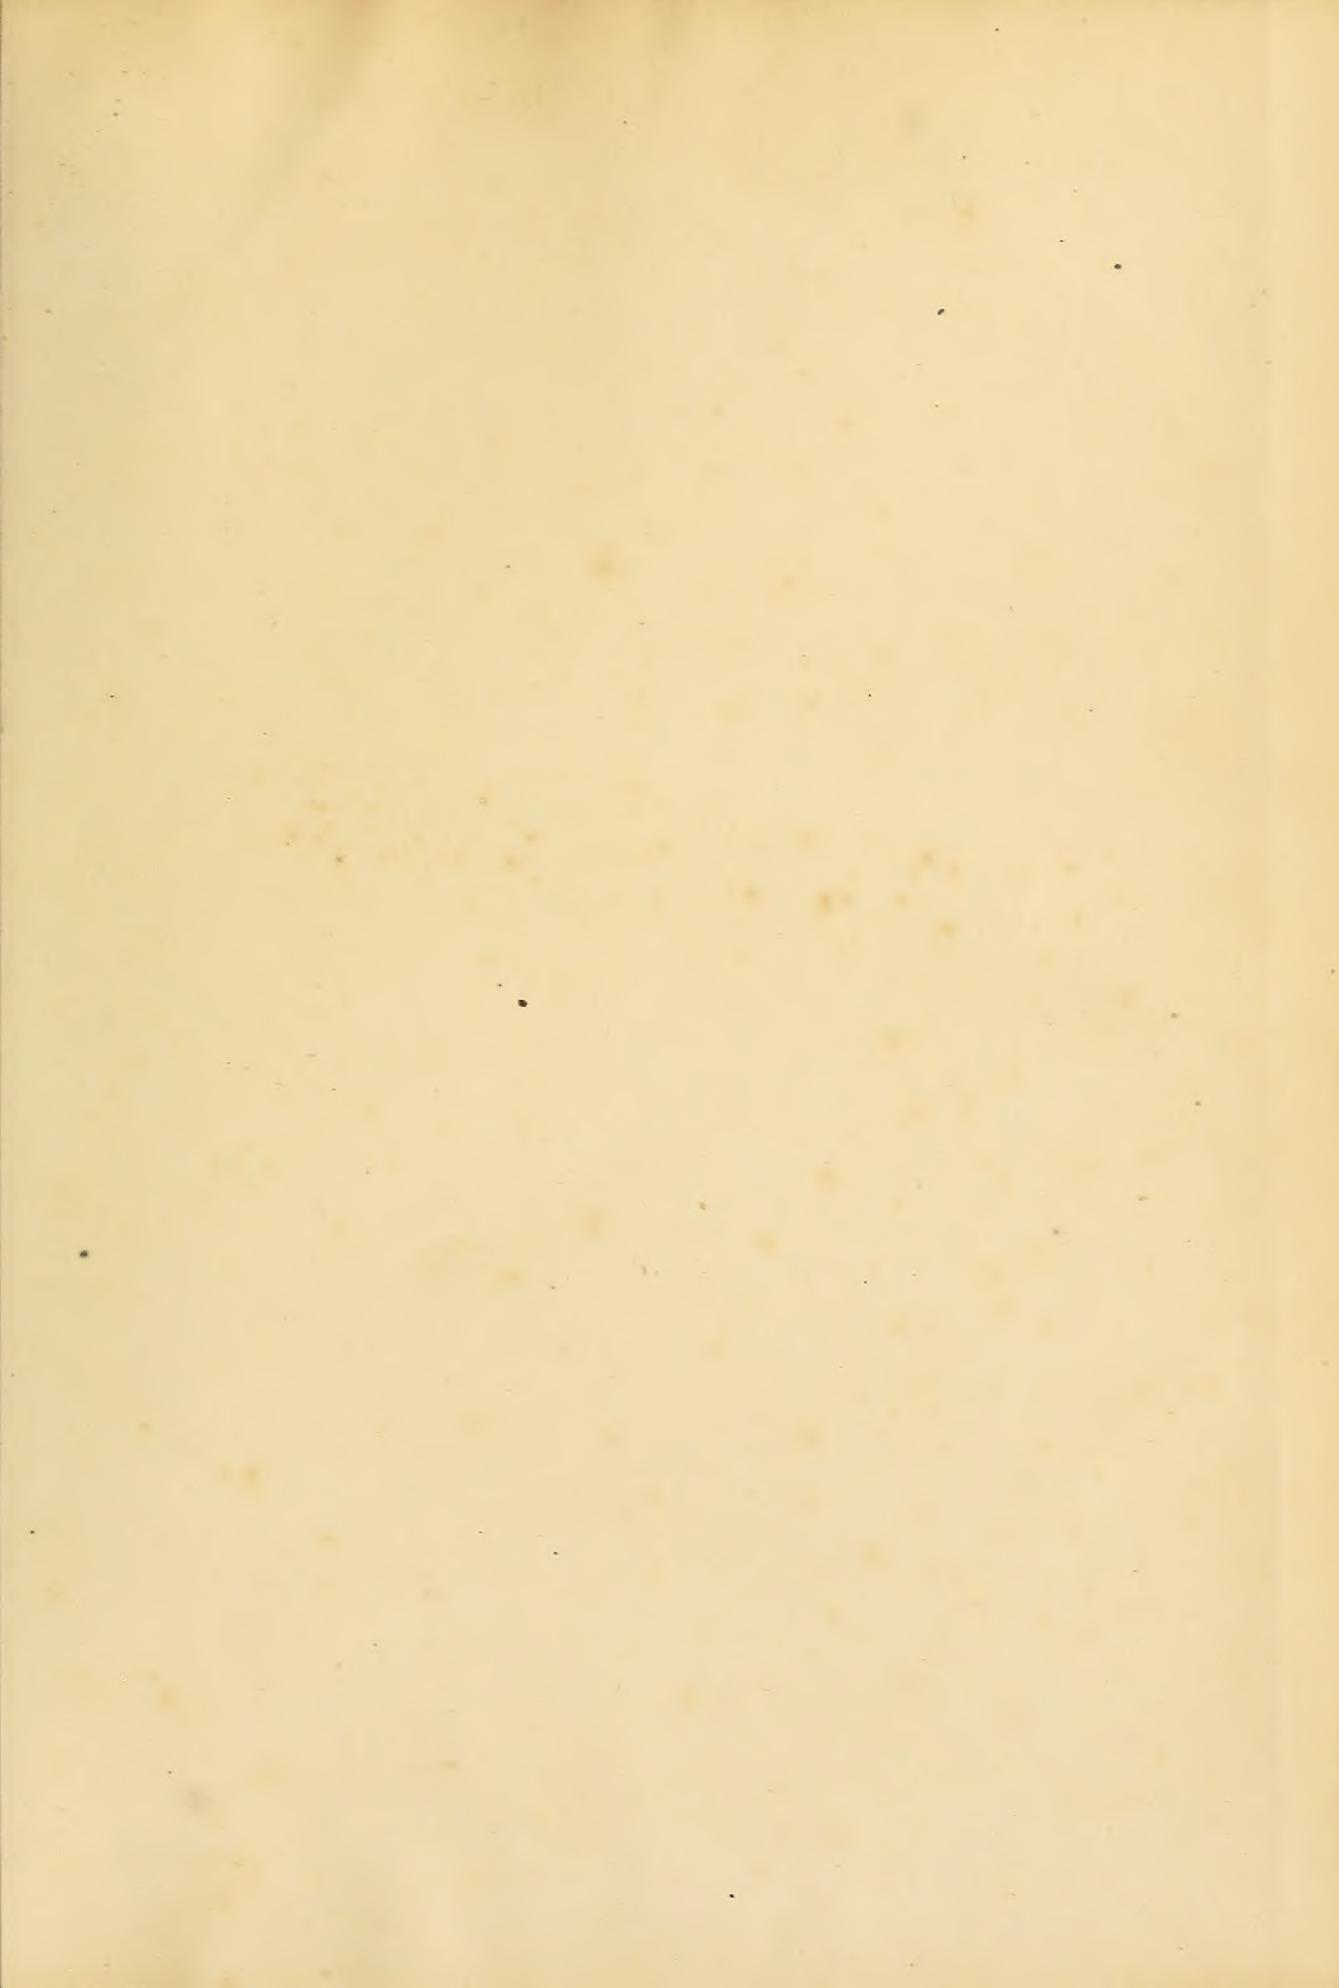

### LONDON MARKETS.—JUNE 26.
